Electrical

THE

TELEGRAPHIC JOURNAL

AND

ELECTRICAL REVIEW.

VOL. XI.

JULY 8—DECEMBER 30, 1882.

LONDON:

H. ALABASTER, 22, PATERNOSTER ROW.

London:
PRINTED BY H. BLACKLOCK & CO.,
FARRINGDON ROAD AND CROSS STREET, E.C.

INDEX.

ACCIDENT from electric lighting, 34
,, Railway, in Germany, 206
Accumulator, The Sellon-Volckmar, 224
Accumulators, Electrical, 34
,, Improvements in, 71, 181, 268
,, Planté and Faure, Chemistry of, 64, 329
Acid, Chromic, elements, 110
Addyman's friction clutch, 348
American Association for advancement of science, 207, 283
Approximative photometric measurements of sun, moon, cloudy sky, electric, and other artificial lights, by Sir William Thomson, 490
Arc circuits, Incandescent lamps on, 366
Aurora Borealis, 419
Ayrton, Professor, and Perry's electric tricycle, 394
,, ,, W. E. and Perry, John, on measuring instruments used in electric lighting and transmission of power, 190

BALLOONS, Military telegraph stations in, 141
Ball's dynamo-electric machine, 50, 131
BATTERY—
Brush's secondary, 70
The Faure storage, 225
New photo-electric, 211
Perry and Ayrton's metallic galvanic, 109
resistance, Measurement of, by Mance's method, 276
Theory of the voltaic, 183
BATTERIES—
Improvements in electric, 184
,, ,, secondary galvanic, 134
New process for rapid formation of secondary couples with plates of lead, 202
Secondary, or accumulators, 154, 197
Testing of low resistance, 233
Baudet's incandescent lamp with magnetic super-excitation, 458
Baudot's telegraph, 8, 43, 212
Bell, Professor, upon the electrical experiments to determine the localisation of the bullet in the body of President Garfield, 491, 509
Bells, electric, and signals at her Majesty's military prison, Lancaster Castle, 489
Bernstein's electric lamp, 285
Berthelot, M., on the electromotive force of a zinc-carbon element, 100
Berthould, Borel and Co.'s electric cables, 368
Bonneau's, M., apparatus for observing direction of currents, 202
Boys, C. V., on electric meters, 218, 277
Brard's, Dr., new system of electric generating apparatus, 203, 508
Breguet regulator, The, 295
Brillouin, M. Marcel, on methods of comparing co-efficients of induction, 165
British Association, Meeting of, 142, 153, 171, 196, 217, 239, 258
Britten's, F. J., watch and clockmakers' handbook, 449
Brockie's electric arc lamp, 406
Brongersma, H., on double refraction in glass and sulphuret of carbon occasioned by electric influence, 110
Brook's underground cable system, 262
Brush Companies, The, and the Lane-Fox lamp, 452
Brush's, C. F., dynamo-electric machine, 70
,, current governor for, 71
,, secondary battery, 70

Burglar alarm exchange system, 311
Burglars and electricity, 156

CABANELLA'S, M. G., theory applied to recent experiments made on transmission of power from Miesbach to Munich, 388
Cables, Interruptions to:—
Fao and Bushire, 287
French Atlantic, 206
Guadaloupe and Dominica, 301
Islay, 70
Key West-Habana, 182
Mull, 13
Shanghai and Amoy, 287
Shetland, 13
West India and Panama, 267
CABLES, NEW:—
Atlantic, 35, 53
Bone-Biserte, 14
Central and South American, 72, 132, 155, 224, 299, 301
Fort Wadsworth to Fort Hamilton, 287
France and Senegal, 311
French Government, for, 90, 182, 246
Great Northern Telegraph Company, 301
Lisbon and United States, 245
Port Said, 133
Red Sea, 28, 72
CABLES, REPAIRS OF:—
Amoy and Hong Kong, 301
Anglo-American, 245
Fao and Bushire, 340
Guadaloupe and Dominica, 326
Havana-Key West, 52
Indo-European, 396
Jamaica and Porto Rico, 464
Mull, 52
Otranto-Corfu, 155
Paris and New York, 140
Rio Grande do Sul and Monte Video, 140
Shetland, 52
St. Thomas and St. Kitts, 286
St. Vincent and St. Lucia, 416
West Coast of America, 13, 364
West India and Panama, 205
CABLE—
Brook's underground system, 261
The Djeddah-Souakin, 346
The French Company, 356
New Atlantic, enterprises, 107
Ship for Post-Office, 301
Siemens', factory in St. Petersburg, 377
Telephone, across the Tay, 440
Underground, between Paris and Marseilles, 155
CABLES—and coral fishers, 246
Electric, 368
Manufacture of submarine, 310
Protection and preservation of, 13
Speed of working through, 90
Tests of Atlantic, "1881," "1882," 169
Underground, in America, 377
,, in Germany, 14
Callender's insulating material, 148
Capanema's insulator, 213
Carbon, Resistance of, and the telephone, 119, 207
Catalogue of the Society of Telegraph Engineers, 502
Chaster's electro-motor, 242
,, telephonic apparatus, 168
Chelsea Surveyor on the electric light, 396, 465
Chemical work, Influence of positive electrode of battery upon its, 15
,, produced by a battery, 14, 134
Chemistry of Planté and Faure's accumulator, 64, 329
City and Guilds of London technological examinations, 108

CITY NOTES (Meetings and Reports of Electric Light, Telegraph, and Telephone Companies, &c.):—
Anglo-American Telegraph Company, 20, 113, 272
,, ,, Brush Electric Light Corporation, 40, 59, 92
,, Austrian (Brush) Electrical Company, 307
Australasian Electric Light, Power, and Storage Company, 231, 272
Birmingham and Warwickshire Brush Electric Light Company, 253, 423
Brazilian Submarine Company, 308, 326, 360
Brush Midland Electric Light and Power Company, 401
,, Electric Light and Power Company of Scotland, 62, 138, 344, 442
Cuba Submarine Company, 20, 40, 60
Devon and Cornwall Electric Light and Power Company, 209, 398
Direct Spanish, 250, 289, 326
,, United States, 62, 94, 308, 344
Duplex Electric Light, Power, and Storage Company, 251
Eastern, 20, 36, 93, 272, 504
,, Electric Light and Power Company, 362
,, Extension, 20, 254, 308, 344, 359, 504
Edison's Indian and Colonial Electric Company, 249
Electric Carbon Storage and Apparatus Manufacturing Company of Scotland, 140
Electric Light and Generator Company, 58
,, Lighting and Maintenance Company, 77
,, News-Telegraph Company, 325
,, Sun Lamp Company, 342
European, American, Canadian, and Asiatic Cable Company, 79
Faure Electric Accumulator Company, 382, 463, 524
Globe Telegraph and Trust Company, 79, 308
Great Northern Telegraph Company, 504
Gülcher Electric Light and Power Company, 185
Henley's Electric Light and Power Company, 98, 290
India-rubber, Gutta-percha, and Telegraph Works Company, 62, 79
Indian and Oriental Electrical Storage and Works Company, 38
Indo-European, 344
Jablochkoff Electric Light and Power Company, 251, 290
London and Provincial Electric Light Company, 210
Mediterranean Extension, 186, 461
Metropolitan Brush Electric Light and Power Company, 76, 136
National Telephone Company, 160
Oriental Telephone Company, 402, 464
Phœnix Electric Light Company, 523
"Pilsen"-Joel and General Electric Light Company, 229
Provincial (Brush) Electric Light and Power Company, 118, 162
Railway and Electric Appliances Company, 93
Reuter's, 308
The J. B. Rogers Electric Light and Power Company, 364
South African Brush Electric Light Company, 57
South Eastern (Brush) Electric Light and Power Company, 116, 162
Submarine Telegraph Company, 95
,, Cable's Trust, 308
Swan Electric Light Company, 250, 504

CITY NOTES—*continued.*
Telegraph Construction and Maintenance, 40, 62, 344
United Telephone Company, 62, 96
West Coast of America Telegraph Company, 325, 342, 364, 504
West India and Panama, 289, 308, 343
Yorkshire Brush Electric Light and Power Company, 232, 266
Clark's Latimer, treatise on transit instrument as applied to determination of time, 449
College, Owen's, Manchester, 393
Commissioners of Sewers and Electric Lighting, 425, 429
Companies, Registration of, 17, 36, 54, 73, 91, 110, 156, 207, 247, 287, 304, 340, 357, 378, 397, 421, 459, 483, 502
Condensers, On singing, 510

THE TELEGRAPHIC JOURNAL AND

Electrical Review.

Vol. XI.—No. 241.

ELECTRIC LIGHT APPARATUS.

The interest felt by all classes in the introduction of the electric light for household purposes is now so universal that the one great question is, "When shall we be able to have this light in our houses?" At present this is rather a difficult matter to deal with, for, notwithstanding all that has been gone through by the Parliamentary Electric Light Committee, we are now at a standstill as far as any important operation is concerned towards solving the problem of domestic illumination. Several well-known gentlemen with unlimited funds have provided for themselves the necessary apparatus wherewith to light their own mansions by means of the incandescent electric lamps, the result, after the first cost, being eminently satisfactory; but the laying down of the necessary plant involves the outlay of a considerable sum, and it is this first expense which is keeping back many who would otherwise invest in a private installation of the electric light. It would really be worth the consideration of electric light companies to endeavour, by a different design, or proportioning of the various parts of dynamo-electric machines, to materially cheapen them, so that the evident desires of many private persons with tolerably good incomes could be met. M. Marcel Deprez has lately demonstrated, both theoretically and experimentally, that a magnetic field of given intensity is least expensive to obtain when it is produced by electro-magnets of considerable dimensions, and he recommends the employment of very powerful inducers surrounded with a *moderate quantity* (the italics are ours) of wire.

It is the wire for winding the bobbins and electro-magnets of these machines which constitutes the most expensive item in their construction, and we quite believe that the electro-magnets may be made much more cheaply and yet be equally as efficient as those now employed. As far as arc electric lamps are concerned, it is not probable that they will trench upon the subject of domestic illumination beyond a slight degree; but as they, too, have their special uses, cheapness in their construction is most desirable. Apparently the lamps of this type which have had the greatest sale have been the most costly, but it is easy to imagine that the demand for them would have been more than quadrupled had their price been reduced to one-fourth of their present scale. There is, however, every possibility of great reduction on this point, for there is, at least, one lamp lately brought before the public which can be made for a few shillings, and will last in action thirty or forty hours without recharging. Even presuming that the use of such a lamp entails the cost of 10 or 20 per cent. extra horse-power, its enormously reduced first cost and ease of manipulation will outweigh such consideration, more especially where the supply of power is unlimited. The question of consumption of carbon, and also of the manufacture of the carbon itself, is of the greatest importance. It will be seen, in the description of the illumination of the North Brussels Telegraph Office in our other pages, that of many experiments with retort and artificially-produced carbons, the best results were obtained with the former. Of course, gas carbon could not economically be used with the ordinary arc lamps; therefore, any system which can employ short and roughly-shaped pieces of gas carbon has a certain advantage over those which necessarily burn carbons artificially made. The manufacture of incandescent lamps has made more progress towards the end in view than any other part of an electric light system; and on the score of expense there is certainly but little to complain of, considering their lasting capabilities, when not forced beyond a normal illuminating power.

The expense attached to the employment of incandescent lamps has been reduced during the last twelve months about five times. This is due to a variety of causes, the principal being, perhaps, the fact that experimental work in this direction can be much more easily carried out than in the case when machines are the subject of investigation. In England, at least, we are deeply indebted to the labours of Messrs. Swan and Lane-Fox, who are practically the pioneers of this branch of electric lighting, and it should be remembered that, whatever improvements may have been made since by others, their path has been rendered easy by the labours of the two gentlemen mentioned.

The cost of conducting wires forms another heavy item in the sum total of a system of electric lighting, yet we have every reason to believe that this will be within a short period reduced nearly 50 per cent. The supply of gutta-percha and india-rubber as insulating materials is limited even now, and it is likely that their cost will be materially increased by the demands for electric light leads. It is therefore necessary that other materials be sought for to answer the same purpose, and this is in a very fair way of being satisfactorily accomplished. The motive power as supplied by steam engines for driving dynamo-electric machines is already established on as economical a basis almost as may be expected, but improvements in gas-engines will doubtless continue for some time to come. But it is not so much to improvements in the apparatus producing our motive power, as to the cheapening of the electrical part of the installation, that we must look to for the increased development of electric lighting. It is quite right and business-like on the part of any company with plenty of work in hand to keep up high prices; but it is no reason why new competitors in the same field should try to emulate the method adopted by the commercially successful company. It is the very object of competition to bring prices down to such a level that both manufacturers and the public receive their fair dues. It is necessary when the demand for certain articles is limited to charge accordingly, but when the demand is likely to become universal, it becomes policy on the part of those supplying the articles to encourage the desire of the public, and not to paralyse or stave it off by the exorbitant sums required for the apparatus. That the wished-for result will arrive sooner or later is a matter of course, but at present electric light companies, with one or two exceptions, show too much apathy towards the very object of their formation, and rapid progress therefore is scarcely to be looked for.

The photometrical results ... the

electric arc and the flame of the candle on the same horizontal line.

The maximum luminous intensity is obtained, with continuous current machines, when a straight line leading from the photometer to the arc makes an angle of 50 to 60 degrees with a horizontal plane.

Not having at our disposal a room sufficiently high to make our experiments under these conditions, we confined ourselves to taking the mean of the intensities. The experiments of M. Hippolyte Fontaine have shown that this average intensity is clearly equal to double that obtained when the arc, the photometer, and the standard light are on the same horizontal line (see *Revue Industrielle*, 9th July, 1879). According to these data, the mean intensity of the light obtained in the Jaspar regulators, burning Siemens' carbons (the positive having a central core, and the negative being of retort carbon), is 1,670 candles, the gas-engine making 160 revolutions and the dynamo-electric machines 955 revolutions per minute.

IV.—*Electric Measurements.*

The length of the circuits, including return wire, connecting the three Gramme machines to the three Jaspar lamps, are respectively 90·5, 120·7, and 140 metres. In order to measure the resistance in ohms of these lengths and that of the coils of the machines, we used a Wheatstone's bridge. After the cooling of the machines we found—

Designation of the Circuits.	Conducting Wires.	Coils of Electro-magnets.	Gramme ring	Solenoid of the Regulator.
First	0·44	0·65	0·88	0·086
Second	0·48	0·66	0·88	0·086
Third	0·53	0·72	0·84	0·086

The resistance of the carbons employed is 0·152 ohms for 0·22 metres of Siemens' carbons, and 0·175 ohms for 0·13 metres of retort carbon. It follows from this that if there had been no other resistance than those already enumerated, the current would have to pass through in each circuit at the commencement of the lighting respective resistances of 1·723, 1·773, and 1·873 ohms.

Each of the circuits, not including the dynamo-electric machines and the lamps, offers an insulation resistance of 55 megohms per kilometre.

When the gas-engine makes 160 revolutions and the Gramme machines 930 revolutions per minute, the intensity of the current measured by Siemens' electro-dynamometer varies between 15 and 16·6 ampères. We found by the method of discharging a condenser that the difference of potential at the terminals of the lamps is approximately 51 volts, and that at the terminals of the Gramme machine 57 volts. If we apply Joule's formula to these results—

$$\text{T} = \frac{\text{I}^2\text{R}}{9{\cdot}81 \times 75} \text{ horse-power.}$$

Where $\text{I} = 15{\cdot}8$ ampères

and $\text{R} = 1{\cdot}8$ ohms

we find $\text{T} = \dfrac{249{\cdot}64 \times 1{\cdot}8}{9{\cdot}81 \times 75} = \dfrac{449{\cdot}352}{735{\cdot}75} = 0{\cdot}61$ horse-power,

which gives us an available force of 24·4 per cent.

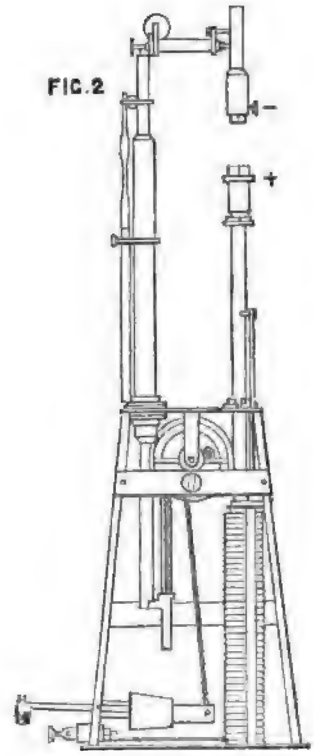
As it is to be supposed that there exists in the arc either an opposing electromotive force or a resistance the preceding formulæ should be modified as to the values to be given to R. This enables us to admit that the available force is greater than that which we obtain by calculation. We cannot, in fact, think that 75·6 per cent. of the effective work is absorbed by the motion of the machines and the heating of the wires.

V.—*Different Methods adopted for Lighting the Rooms at North Brussels.*

The first plan adopted for the lighting was to place three lamps on tripods at the points marked 1, 2, and 3, in fig. 1. In the three lamps, placed at a height of 2·75 metres, the positive carbon was underneath, so that the light was thrown on the ceiling and walls, partly directly, and partly by the help of a reflector, R (*see* figs. 2 and 2*a*). A cylinder, V, formed of sheets of glass, placed on the reflector, R, and a truncated cone of ground glass, G, obviated the projections of incandescent carbon. The globe, G, also prevented the light from striking directly on the eyes of those *employés* near the lamp.

By this method a light was obtained which was more than sufficient, but not very steady.

FIG. 2



This want of steadiness arises from the reverse employment of the lamp: the hollow, which is formed at the extremity of the positive carbon placed underneath, becomes filled with impurities contained in the carbon; these substances, on becoming fused, produce variations in the intensity of the light. This method of lighting was continued until the 15th

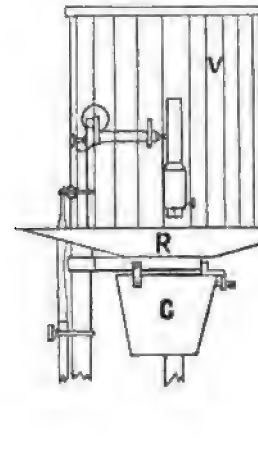


FIG. 2a

of February, 1880. At that date M. Jaspar modified the system by adopting a double reflection of the light. The positive carbon of the regulator was placed at the top of the lamp. (*See* figs. 3 and 4.) The light is reflected on the ceiling by horizontal mirrors, M, N, and M′N′, directed downwards. In order to hinder the full light from dazzling the operators, the luminous arc is enclosed in a truncated quadrangular pyramid, R, S, T, U, of sheet iron nickeled inside; the base of the pyramid is turned upwards. By

this means we obtained a very steady light, although the quantity of light utilised is not so great, on account of the reflection on the mirrors, as that resulting from the first method, it is still more than sufficient for the *employés* who attend to the telegraphic instruments. By using lamp No. 1, which belongs to the first room, we were able to light the little sorting room, which leads to the two instrument rooms. With this object the regulator of the first room (*see* fig. 5) bears a crown of six lenses, on which rests a horizontal

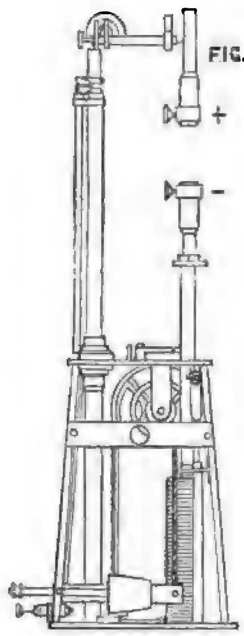

FIG. 3

nickeled reflector. The rays of the cone formed by the lenses are normal to those of the crater of the positive carbon. This arrangement allows of luminous sheaves being sent out by means of plane mirrors in six different directions. One of these sheaves is intercepted by another plane mirror, D (*see* fig. 1), which directs it on to a white blind, *b*, from which the light is reflected on to the pigeon-holes.

A second beam is directed to C, above the clerk who occupies the desk placed in this room. In order to prevent the luminous arc from dazzling the eyes it was enclosed in an elliptical truncated cone of sheet iron, nickeled inside. The luminous point occupies a focus of one of the horizontal sections.

VI.—*Experiments with different Carbons for Regulators.*

We tried the principal carbons known: the gas carbons, Carré's, Gauduin's, Siemens' coppered carbons, and those with central core, of Siemens Brothers, of different diameters. The majority of the artificial carbons gave bad results, the light changing frequently in intensity and colour. The best results were obtained with the gas carbons prepared with borax, and those of Siemens Brothers, with central core of plumbago, either used singly, or together with different diameters. The most advantageous combinations are the following:—

I. Two 9-millimetre square gas carbons.

II. Two square gas carbons, one of which, forming the positive pole, is 11 millimetres, and the other 9 millimetres.

III. A round carbon of Siemens Brothers, 14 millimetres in diameter, forming the positive pole, and a 9-millimetre square gas carbon, for the other pole. With a length of 22 centimetres for the carbon, which becomes hollowed out, and of 13 centimetres for the other (35 centimetres altogether), the first combination allows of an illumination of 3½ hours, and the two other combinations of 4½ hours.

VII.—*Attention required by the Apparatus.*

The daily attention required by the gas-engine is the same that necessary for all motors of the same kind.

The Gramme Machines.

The precautions to be taken in regard to these machines can be summed up as follows:—

1. The brushes should never be loosened while the current is established, because the spark which would be produced at the moment of their separation from the commutator, would burn the copper wires, of which they are composed.

2. The brushes should be moderately light, so that the pieces of bronze which support them may not rub against the commutator and wear it out. The wires of the brushes alone should rest upon it.

3. The position of the brushes being of great importance, it should be examined, and noted down at the time of the arrival of the machines, so that if shifted it may be re-established.

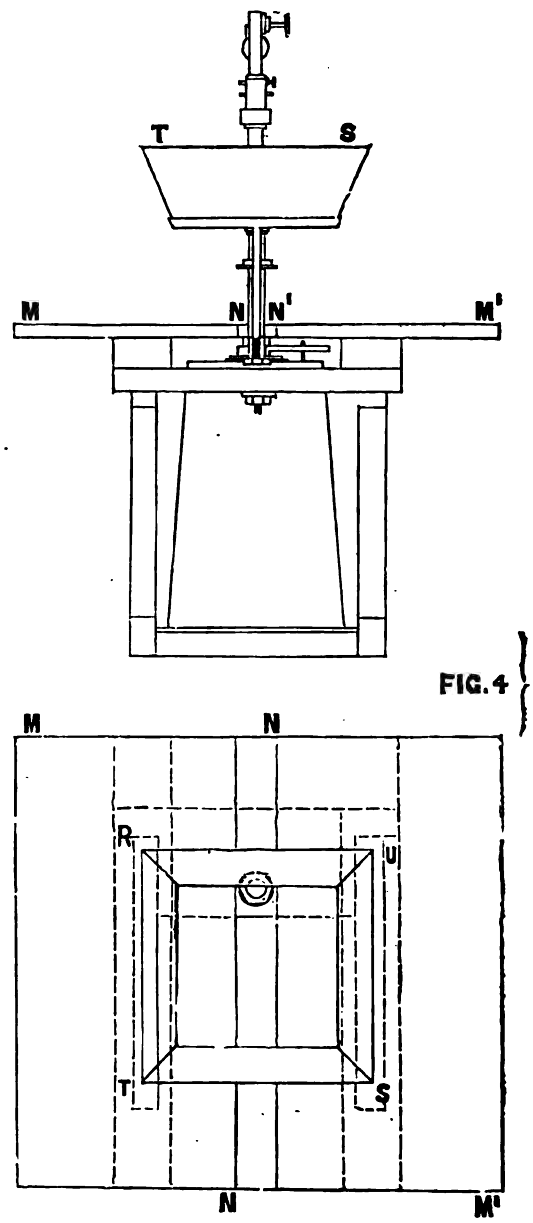

FIG. 4

4. If, by accident, the ends of the brushes should be burnt, the melted part should be cut off neatly, the brush should be pushed forward, so as to restore it to its original length, and then the ends should be filed, or sharpened so as to give them their former shape. Very few sparks should be produced at the point where the brush rubs against the commutator. Large sparks would indicate that the brushes are either badly placed, or not in good condition.

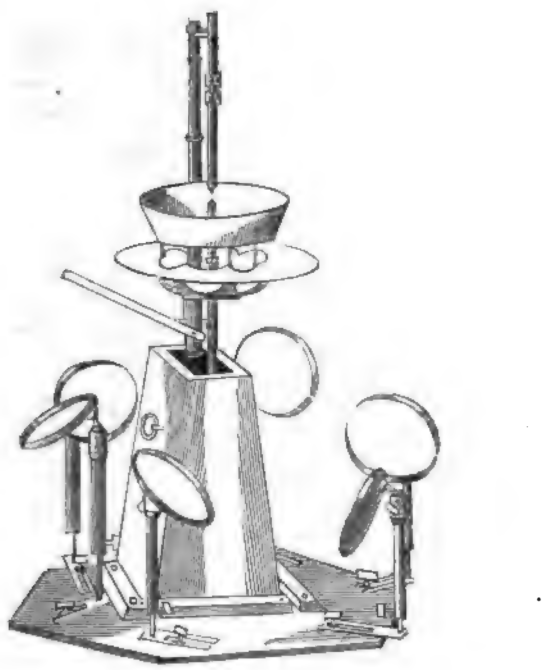
5. In order to avoid the wearing out of the brushes, it is advisable, now and then, to grease the commutator with a little oil on a rag, but care must be taken that the quantity of oil used is not sufficient to clog the brushes or to increase appreciably the electrical resistance of the circuit.

6. The driving-band should be kept tightly stretched.

7. All the machines should be in order before being put in motion. It may be ascertained whether the current is established by bringing a piece of iron near the ring at the top of the inductor; if it is attracted the current is circulating.

8. It is indispensable that the speed of the motor should be very regular; the bobbin of the Gramme machine should perform 900 to 1,200 revolutions per minute. If, after running about an hour, the dynamo-electric machine should

FIG 5



become heated beyond 100 degrees Centigrade, the speed must be lessened; if, on the contrary, the temperature does not exceed twenty or thirty degrees Centigrade, the speed must be increased.

The heating depends on the greater or less resistance of the wire connecting the machine with the lamp. The longer the wire is and the less its diameter the more its resistance increases, and, consequently, the more must the speed of the machine be increased.

9. The screws which fix the bobbin to the axle should be examined from time to time to see whether they have become loosened.

The Jaspar Lamp.

Fig. 3 gives an illustration of the Jaspar lamp. The lower carbon-holder is in electrical communication with the frame of the apparatus, and the other is completely insulated from it. The two carbon-holders are each guided by a vertical rod, which is fitted into a cylinder filled with mercury. Two cords, connnected by two pullies, the diameter of one being double that of the other, to the two rods supporting the carbons, regulate the distance between them, so that the distance traversed by the positive carbon is almost double that passed through by the negative carbon. A weight, which slides along a horizontal bar, is connected by a cord to a third pulley, fixed upon the axle of the two first.

The extremity of the rod of the lower carbon-holder, which is of soft iron, passes into a solenoid, which, by the magnetic attraction resulting from the passage of the current through its spirals, maintains a distance of three millimetres between the points of the carbons. When this distance is increased the intensity of the current is diminished, and the carbons come closer together. The object of the weight, which acts in an opposite direction to the electric current, is to enable the regulator to be employed for currents of very different intensities. The mercury in the two cylinders, in which are fixed the rods guiding the carbon-holders, prevents the sudden bringing together of the carbons, and insures good contact between the lower rod and the frame of the apparatus.

The lower part of the regulator is protected from the dust and from shocks by an envelope of varnished sheet-iron fixed to the woodwork of the apparatus by two screw-hoops, serving as handles for carrying about. The precautions to be taken in the manipulation of these regulators are as follows:—

I. Before starting them the rings should be unscrewed, the sheet-iron envelope taken off, raising it very carefully upwards, and 300 grammes of very pure mercury should be poured into the cylinders, taking care to move slowly the rod bearing the piston, in order to expel the air contained under it.

II. To make sure, before putting back the envelope, that the cords have not slipped from the grooves of the pulleys, and that the movable parts work quite freely. If everything is in order, and if the carbon-holders are drawn away from each other by pushing down the lower carbon, the two carbons should come slowly together, without jerk or break, as far as they can go.

III. The weight being drawn to the middle of the rod which bears it, the lamp is in readiness for the Gramme machine, revolving at 900 turns. The distance between the carbons during the action of the regulator is then 3 mm.

IV. To insure before lighting that no mercury has gone out of the cylinders, to work by hand the mechanism, and, if the movement of the carbon-holder is not regular, to clean the cylinder and its piston and filter the mercury through flannel.

V. To keep clean the rods of the carbon-holders by wiping them with a dry linen cloth, and if the apparatus has become clogged, to take it all to pieces and thoroughly clean the rubbing surfaces.

VI. In case the cords should break, to replace them by new ones, taking into consideration their respective lengths between the knots. These lengths are as follows:

For the large wheel	...	...	$0^{m}.260$
The next size ...	...	...	$0^{m}.185$
For the small wheel	...	...	$0^{m}.240$

VIII. The comparative cost of the lighting by gas and the lighting by electricity which have been used successively at the office of North Brussels.

A.—*Labour and Consumption of Material.*

Before the employment of the electric light, the large instrument-room was lighted by 47 gas-jets, the smaller one by 21, and the room leading into them by 2—or, altogether, 70 jets—each consuming 140 litres per hour. The total consumption was, therefore, $9^{m3}.800$ per hour.

This being at the rate of 0.15 fr. the cubic metre, the expense amounted to 1.47 fr. per hour for the complete lighting of the three rooms. To this price we must add 0.15 fr. for the glass chimneys and smoke-consumers, which brings it up to 1.62 fr.

In working the three Gramme machines, the gas-engine consumes about 8 cubic metres of gas per hour, which costs 0.15 fr. $\times$ 8 = 1.20 fr.

The lubricating of the Otto motor take half a litre of oil per day. The management of the machine and lamps is intrusted to one man, who receives a monthly salary of 120 frs., or 4 frs. per day.

The arrangement of the wires and telegraph instruments at the office of North Brussels necessitates the burning of gas all through the night. After 9.30 p.m. only a few of the instruments are used for the transmission and reception of despatches; at 11 o'clock, when the night service commences, this number is still less. The instruments at work after that time are scattered in various parts of the two rooms. The operators then require for their work a limited amount of light, easily obtained by lighting a few gas-jets.

As on the shortest days six hours of electric lighting are required (from 3.30 to 9.30 p.m.), and on the longest two hours (from 7.30 to 9.30 p.m.), we have on an average a duration of four hours. It is upon this average that we calculate the cost of the three lamps.

The total length of the carbons used with the Jaspar regulator does not exceed $0^{m}.35$, $0^{m}.22$ for the positive carbon, and $0^{m}.13$ for the negative.

By burning gas carbons 9 millimetres square, or gas carbons 11 millimetres square for the positive pole and

9 milimetres for the negative, or else Siemens Brothers' round artificial carbons with central core, 14 millimetres in diameter for the positive pole, and gas carbons 9 milimetres square for the negative, we arrive at the following results :—

In one lamp we burn, in 3½ hours, $0^m.35$ of gas carbon 9 millimetres square; in 4½ hours $0^m.22$ of gas carbon 11 millimetres square and $0^m.13$ of gas carbon 9 millimetres square; in 4½ hours $0^m.22$ of Siemens Brothers' round carbons, 14 millimetres in diameter, and $0^m.13$ of gas carbon 9 millimetres square.

If we bring this rate of consumption to an average duration of 4 hours, we find that we burn :

I. $0^m.40$ of carbon, 9 millimetres square.

II. $0^m.20$ of gas carbon 11 millimetres square, and $0^m.12$, 9 millimetres square.

III. $0^m.20$ of Siemens Brothers' carbons, 14 millimetres in diameter, and $0^m.12$ of gas carbon, 9 millimetres square. From these data, it follows that the cost of labour and consumption of material in producing the electric light by means of three Jaspar lamps, for 4 hours, can be estimated as follows :

	Frs.
Carbon...	2.24
32 cubic metres of gas at 0.15 fr.	4.80
½ litre of oil, rags, &c.	0.75
Salary of workman	4.00
Total ...	11.79

Or 2.95 frs. per hour.

We have already found that the cost of consumption with lighting by gas amounts to 1.62 fr. per hour.

B.—*Cost of the two Methods of Lighting.*

The cost of a complete installation of gas-pipes, meter, &c., such as that used at the office of North Brussels, may be estimated at 50 frs. per burner. The seventy burners used in three instrument-rooms cost, therefore, for installation, 70 × 50, or 3 500 frs.

For lighting by the electric light we have, for the cost of installation :—

	Frs.
3 Gramme machines, workshop type	4,500
3 Jaspar regulators	840
3 tripods of variable height	74
3 commutators	81
350 metres of insulated wires and cable	350
Accessories for the regulators	300
An eight-horse gas-engine	5,970
Fixing of the motor and instruction of workman ...	650
Total ...	12,765

Calculating the interest and repairing in the proportion of 10 per cent., we get, in the two cases :—

a. For gas : 0.96 fr. per day, or 0.24 fr. per hour of lighting.

b. For the electric light : 3.49 fr. per day, or 0.87 fr. per hour of lighting.

The actual cost of lighting per hour amounts, therefore :—

I. For gas : to 1.86 fr.

II. For the electric light : to 3.82 frs.

Thus, the electric light costs 2·05 times as much as gas.

If we take into account the luminous intensity, we find that one candle-power per hour of gas costs 0.0035 fr. (one gas-jet being equal to 7½ candles), and one candle-power per hour of electric light costs 0.00076 fr.; *i.e.*, 4 6 times less than gas.

IX.—*Concluding remarks.*

In rooms like those in which the telegraph instruments are placed at North Brussels, where the ceiling is low and the number of *employés* somewhat numerous, the use of gas for lighting seriously affects the health of the occupants. Gas vitiates the air by transforming part of the oxygen into carbonic acid, and also by heating it excessively.

The electric light presents none of these inconveniences : very little oxygen is absorbed, and the temperature is not appreciably raised. The work is performed about as easily as by daylight, the reading of the slips is rendered easier, and the operators are not so fatigued, all of which is very advantageous for the regularity and celerity of the service.

We give an extract from a letter addressed to the Administration by M. le Percepteur of North Brussels, January 12th, 1880 :—

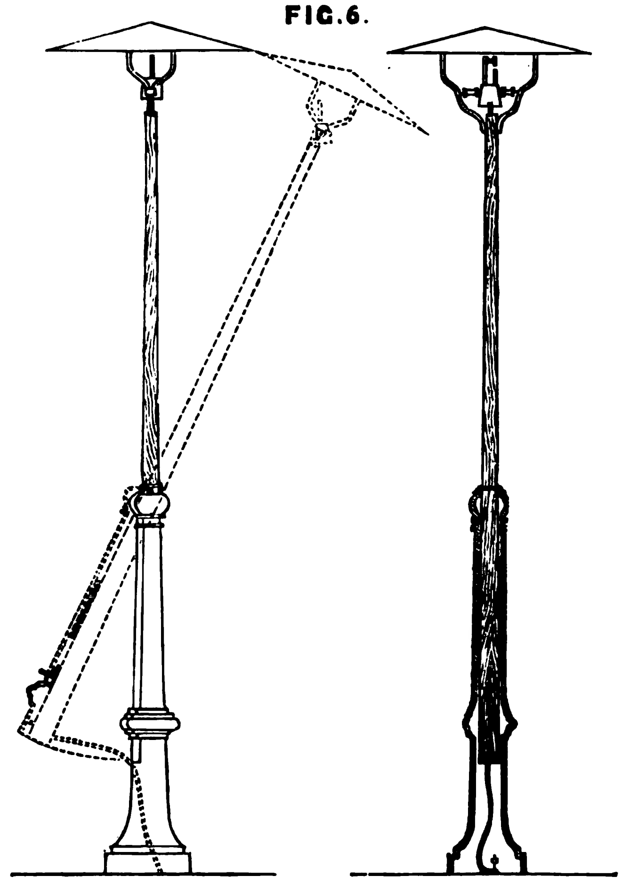
> Thanks to the light produced, which is almost equal to daylight, the work is performed with less fatigue than by gas-light, and the operators who, during the winter, pass seven hours after dark at the office, find themselves much fresher after their work than usual. The temperature of the room is no longer that of a furnace, as was formerly the case. We have received no complaint about the adoption of the electric light from any of the *employés*, and it is a great disappointment to them when it cannot be employed.

X.—*The Lighting of a Public Place.*

The success of the electric light at the Telegraph Office at North Brussels decided the Administration of Railways to attempt, in co-operation with the parochial authorities of Saint-Josse-ten-Noode, a trial of lighting, opposite the principal entrance of the Northern Railway station.

For this purpose a gas-engine of eight horse-power was installed to work three Jaspar regulators, destined to light the space opposite the station. The three lamps were placed at

FIG. 6.



a height of about 9 metres, one in the middle of the *façade* of the station, on the building itself; the two others in the Place des Nations, so that the light should be shed equally over the space to be lighted.

Each lamp is surmounted by a reflector of whitened sheet-iron, of conical shape. Behind the regulator, placed on the station, is a reflector composed of two plane mirrors, which send the light towards the centre of the space. The three burners are enclosed in globes of alabaster glass, which diffuse the light around.

The two regulators in front of the station are placed on candelabra, shown at fig. 6. A bracket, to the extremity of which the lamp is suspended, turns on an axle, and thus enables the carbons to be renewed. The two parts of the bracket are equalised so as to be easily managed. The plinths of the candelabra are of cast-iron.

The lamp has a divided axle, the two ends of which are inserted into pivots fixed to the candelabrum, and thus it can swing during the descent of the bracket.

The three Jaspar regulators are advantageously substituted in lighting the Place des Nations and the approaches

to it for 20 ordinary gas-lamps, consuming 200 litres per hour, and two Sugg burners, consuming 1,400 litres per hour.

The cost of the two methods of lighting can be estimated as follows:—

INSTALLATION.

I.—Of the electric light.

	Frs.
3 Gramme machines, workshop type	4,500
3 Jaspar regulators	840
3 commutators	60
Wires and underground cable	550
2 candelabra	320
Accessories for the lamp on the building	100
An 8 horse-power gas-engine	5,970
Total ...	12,340

II.—Of gas.

	Frs.
20 Ordinary gas lamps, with burner	3,000
2 " " with Sugg burner... ...	1,200
Total ...	4,200

The cost of labour and consumption of material, supposing the duration of lighting to be six hours per day, amounts to:—

	Frs.
Carbons for regulator	3.36
48 cubic metres of gas at 0·15 fr.	7.20
Oil, rags, &c.	0.75
Salary of workman	4.00
Total ...	15.31

or 2·25 frs. per hour.

The cost of consumption of material with lighting by gas amounts to 1·02 fr. per hour.

The cost per hour is, therefore, as follows:—

I.—Electric light.

	Frs.
Interest and repairing of installation, at 10 per cent.	0.56
Labour and consumption of material	2.55
Total ...	3.11

II.—Gas.

	Frs.
Interest and repairing of installation, at 10 per cent.	0.19
Gas consumed	1.02
Total ...	1.21

Under these conditions, the price of lighting by gas is 2·57 times less than that of lighting by electricity. If we calculate, as before in the lighting of the office, the cost per candle-power per hour, we should find that the electric light is much more economical than gas.

FIRE RISKS FROM ELECTRIC LIGHTING.

RULES and regulations for the prevention of fire risks arising from electric lighting, recommended by the Council of the Society of Telegraph Engineers and of Electricians in accordance with the report of the committee appointed by them on May 11, 1882, to consider the subject.

Members of the committee.—Professor W. G. Adams, F.R.S., vice-president; Sir Charles T. Bright; T. Russell Crampton; R. E. Crompton; W. Crookes, F.R.S.; Warren De la Rue, D.C.L., F.R.S.; Professor G. C. Foster, F.R.S., past president; Edward Graves; J. E. H. Gordon; Dr. J. Hopkinson, F.R.S.; Professor D. E. Hughes, F.R.S., vice-president; W. H. Preece, F.R.S., past president; Alexander Siemens; C. E. Spagnoletti, vice-president; James N. Shoolbred; Augustus Stroh; Sir William Thomson, F.R.S., past president; Lieut.-Colonel C. E. Webber, R.E., president.

These rules and regulations are drawn up not only for the guidance and instruction of those who have electric lighting apparatus installed on their premises, but for the reduction to a minimum of those risks of fire which are inherent to every system of artificial illumination.

The chief dangers of every new application of electricity arise mainly from ignorance and inexperience on the part of those who supply and fit up the requisite plant.

The difficulties that beset the electrical engineer are chiefly internal and invisible, and they can only be effectually guarded against by "testing" or probing with electric currents. They depend chiefly on leakage, undue resistance in the conductor, and bad joints, which lead to waste of energy and the production of heat. These defects can only be detected by measuring, by means of special apparatus, the currents that are, either ordinarily or for the purpose of testing, passed through the circuit. Bare or exposed conductors should always be within visual inspection, since the accidental falling on to, or the thoughtless placing of other conducting bodies upon, such conductors might lead to "short circuiting" or the sudden generation of heat due to a powerful current of electricity in conductors too small to carry it.

It cannot be too strongly urged that amongst the chief enemies to be guarded against are the presence of moisture and the use of "earth" as part of the circuit. Moisture leads to loss of current and to the destruction of the conductor by electrolytic corrosion, and the injudicious use of "earth" as a part of the circuit tends to magnify every other source of difficulty and danger.

The chief element of safety is the employment of skilled and experienced electricians to supervise the work.

I. THE DYNAMO MACHINE.

1. The dynamo machine should be fixed in a dry place.
2. It should not be exposed to dust or flyings.
3. It should be kept perfectly clean and its bearings well oiled.
4. The insulation of its coils and conductors should be perfect.
5. It is better, when practicable, to fix it on an insulating bed.
6. All conductors in the dynamo room should be firmly supported, well insulated, conveniently arranged for inspection, and marked or numbered.

II. THE WIRES.

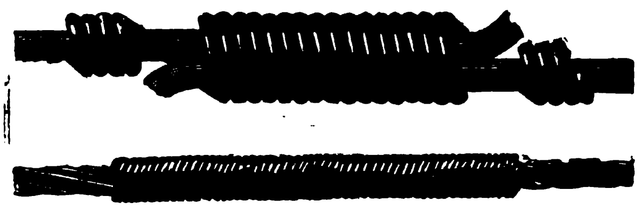
7. Every switch or commutator used for turning the current on or off should be constructed so that when it is moved and left to itself it cannot permit of a permanent arc or of heating, and its stand should be made of slate, stoneware, or some other incombustible substance.
8. There should be in connection with the main circuit a safety fuse constructed of easily fusible metal which would be melted if the current attain any undue magnitude, and would thus cause the circuit to be broken.
9. Every part of the circuit should be so determined, that the gauge of wire to be used is properly proportioned to the currents it will have to carry, and changes of circuit, from a larger to a smaller conductor, should be sufficiently protected with suitable safety fuses so that no portion of the conductor should ever be allowed to attain a temperature exceeding 150° F.

N.B.—These fuses are of the very essence of safety. They should always be enclosed in incombustible cases. Even if wires become perceptibly warmed by the ordinary current, it is a proof that they are too small for the work they have to do, and that they ought to be replaced by larger wires.

10. Under ordinary circumstances, complete metallic circuits should be used, and the employment of gas or water pipes as conductors, for the purpose of completing the circuit, should in no case be allowed.
11. Where bare wire out of doors rests on insulating supports, it should be coated with insulating material, such as india-rubber tape or tube, for at least two feet on each side of the support.
12. Bare wires passing over the tops of houses should never be less than seven feet clear of any part of the roof, and they should invariably be high enough, when crossing thoroughfares, to allow fire escapes to pass under them.
13. It is most essential that the joints should be electrically and mechanically perfect. One of the best joints is that shown in the annexed sketches. The joint is whipped around with small wire, and the whole mechanically united by solder.
14. The position of wires when underground should be efficiently indicated, and they should be laid down so as to be easily inspected and repaired.

15. All wires used for indoor purposes should be efficiently insulated.

16. When these wires pass through roofs, floors, walls, or partitions, or where they cross or are liable to touch metallic masses like iron girders or pipes, they should be thoroughly protected from abrasion with each other or with



the metallic masses, by suitable additional covering; and where they are liable to abrasion from any cause or to the depredations of rats or mice, they should be efficiently encased in some hard material.

17. Where wires are put out of sight, as beneath flooring, they should be thoroughly protected from mechanical injury, and their position should be indicated.

N.B.—The value of frequently testing the wires cannot be too strongly urged. It is an operation, skill in which is easily acquired and applied. The escape of electricity cannot be detected by the sense of smell, as can gas, but it can be detected by apparatus far more certain and delicate. Leakage not only means waste, but in the presence of moisture it means destruction of the conductor and its insulating covering, by electric action.

III. Lamps.

18. Arc lamps should always be guarded by proper lanterns, to prevent danger from falling incandescent pieces of carbon, and from ascending sparks. Their globes should be protected with wire netting.

19. The lanterns, and all parts which are to be handled, should be insulated from the circuit.

IV. Danger to Person.

20. To secure persons from danger inside buildings, it is essential so to arrange the conductors and fittings, that no one can be exposed to the shocks of alternating currents exceeding 60 volts; and that there should never be a difference of potential of more than 200 volts between any two points in the same room.

21. If the difference of potential within any house exceeds 200 volts, whether the source of electricity be external or internal, the house should be provided outside with a "switch," so arranged that the supply of electricity can be at once cut off.

By order of the Council,

F. H. WEBB, *Secretary*.

THE BAUDOT TELEGRAPH.

(Sixth Article.)

Combiner (*continued*).—We shall now describe the combiner according to the practical form which it takes in M. Baudot's last models.

Fig. 7 shows the plan. We see ten concentric rings, representing the five pairs of grooves (normal and complementary), distinguished one from another by different signs. The shaded parts correspond to the projections and the white to the hollows. It must be borne in mind that an immense number of similar tables could be compiled, since, with the five effects necessary to form a signal, we obtain for our computation the product $1 \times 2 \times 3 \times 4 \ldots\ldots \times 29 \times 30 \times 31$. We will confine ourselves to the table chosen by the inventor.

In this table the projections and hollows do not occupy the entire circumference. A sector, equal to $\frac{13}{78}$ths, is reserved for the insertion of fixed stops, placed on the complementary grooves or those in action, and represented in black on the diagram. These stops serve for the pointing. The needles occupy $\frac{5}{78}$ths in this sector. When at rest the needles close the groove of action, and the rubbers then follow the grooves of rest; the frame does not fall, and no impression is made. The two grooves of each rubber are separated by a partition which prevents it from passing into the groove of action before having been directed there by the needle. There is no partition in the sector reserved for the pointing; the change of direction can be effected at this part only. The two grooves of one rubber are separated from the next by a partition extending all round the circumference. Besides the ten rings represented in fig. 7, we see an eleventh which encloses the others. It is equally divided into projections and hollows. These divisions are distributed in such a manner that the hollows always project over the spaces in the first groove of action. An examination of the figure will clearly show the advantage of this arrangement. The movement of the chariot bearing the five normal runners being determined in the three pairs of grooves according to the pointing, if the chariot has a sixth runner specially designed for this supplementary eleventh groove, the result will be that the fall of the frame brought about by the formation of the combination (say, five hollows) will only take place when the rubber itself corresponds to a space. We thus do away with one cause of deterioration which would otherwise lead to the rapid wearing out of the grooves of the table and of the collectors every time a change is made from a hollow to a projection after the production of a combination. The transfer is made only on one ring and one collector.

Fig. 8 shows the details of the combiner, and the arrangement of the hollows and projections corresponding to the letters of the alphabet. Above this is shown the system of the five rubbers (the sixth, before mentioned, is omitted, as it has no connection with the pointing). The five rubbers are fixed vertically and movable on a pivot horizontally. They support a frame which is constantly drawn down by a spring, *v*.

If the explanations already given are referred to, it will be seen how the displacement of a rubber is equivalent to the substitutions we had imagined in order to explain the formation of the combinations. The needle being actuated will close the entrance of the groove of rest, and direct the rubber into the groove of action. If the first needle is displaced in the forward movement of the frame, the first rubber will follow the groove of action, and the four others will remain in their respective grooves of rest; at the first division, a space coming under each of the five rubbers simultaneously, the frame will fall.

With the displacement of the second needle, the fall of the frame will take place at the second division, and so on for each of the combinations. The function of the frame is, in short, that of a collector seeking the place where it is to fall, a point always determined by the combination corresponding to the letter to be printed.

We will now consider the mechanism of the pointing. In the first brief description we said that the five keys of the manipulator at the post of arrival corresponded to the five electro-magnets, the armatures of which repeated the combination formed by the keys. We see, therefore, how the movement of these armatures can be utilised for affecting the action of the needles. In reality the line current does not act directly on the electro-magnets; it puts in motion relay which works them by a local current. The description of the relay employed by M. Baudot will be given subsequently; we shall first explain how the movement of the armatures of the pointing electro-magnets is transmitted to the needles.

The five electro-magnets are fixed against a plate in the apparatus. At the moment when the local current passes into an electro-magnet the armature is attracted, and, pressing against one extremity of the rod, *t* (fig. 9), enables it to push the appendage, *a*, of the lever of the needle. An index, *i*, of thin sheet-iron, fixed on the screw, *v*, of the armature and outside the plate, enables the movement of the armature to be controlled.

When the pointing electro-magnet is no longer influenced, the armature is brought back to rest by the rod [illegible] actuated by the spring, *v*. The needle is maintained in the app[illegible] position in which it has been placed by means of a rolle[illegible] fixed to a

THE TELEGRAPH ENGINEERS' SOCIETY AND THE ELECTRIC LIGHT.

WE cannot congratulate the members of the committee, appointed by the Society of Telegraph Engineers and of Electricians to investigate the fire risks attached to the employment of the electric light, in having produced a report which can in any way be considered superior to that brought forward some time since by Mr. Heaphy, C.E., for the guidance of the Phœnix Fire Office. As a matter of fact, this gentleman's single-handed production deals more exhaustively with the entire subject than does the meagre amount of matter collected by the committee of the Telegraph Engineers' Society. We cannot think that the majority of the gentlemen named had any hand whatever in framing this report, or the result would have been more worthy of their reputation. We would undertake to say that, had Professors Ayrton and Perry been commissioned to draw up a report on this important subject, we should have had, at least, something material added to our present knowledge, and many valuable suggestions, which would not probably occur to those whose minds and time are actively engaged in daily practical work, would have been brought forward.

One would naturally have expected, not necessarily a voluminous amount of matter from this committee, but at least sufficient information, embodied into the form of rules, as to be looked upon in the light of an authoritative and exhaustive treatise. Instead of this, we are treated to a mild and condensed account of what we should imagine everybody had read before. The six rules relating to the dynamo machine contain absolutely nothing but what every electrical engineer would do his best to arrange for. The information relating to the wires is not nearly so thoroughly treated as by Mr. Heaphy in the report above referred to; and although we did not see the force of some of the rules proposed by that gentleman, he had apparently been to a considerable amount of trouble in investigating the matter; and, in the end, produced a far more creditable attempt at efficiently dealing with fire risks from the electric light than the pamphlet before us.

In no part of this report is any suggestion thrown out as to any simple or convenient means of following up the outlined ideas of the Committee. The Society of Telegraph Engineers should be aware that the electric light engineer of the present day is in almost every instance a creation of the last three or four years, and that many hints which may be quite apparent to a professional electrician require a simple explanation or example to be of service to the latest comers in electrical work. For instance, if we take the following example it will illustrate our meaning:—Rule 15 reads, "All wires used for indoor purposes should be efficiently insulated." Now what will this convey to the mind of a man who does not know in what terms the meaning of insulation is expressed, or in what degree the different properties of insulating materials may vary. The only service which we can imagine this pamphlet will render towards the object in view is in the strongly-urged remark, that the chief element of safety is in the employment of skilled and experienced electricians and in the frequent testing of the wires.

As a recommendation from the Council of the Society of Telegraph Engineers and of Electricians the Report is utterly unworthy of the Society's reputation. The subject is merely touched upon, and that in the flimsiest manner, and although the intention of the Committee may have been a good one we can only come to this conclusion, that it has failed unmistakably in producing a work which will ever be looked upon as authoritative, useful, or containing anything whatever beyond that which electric light engineers already know. We are sorry that so many eminent men should have allowed this pamphlet to be brought forward with their sanction. England is looked upon by Continental and American electricians as the leading country in electrical science, but we do not think that any prominent body of engineers abroad would produce such a miserable offspring as that brought forth by the Society of Telegraph Engineers and of Electricians.

ARC ELECTRIC LIGHTS FOR LARGE INDOOR SPACES.

IN our columns of this week will be found an interesting description of the lighting of the telegraph office at North Brussels by the Jaspar system of arc lamp. Although this installation was commenced as long since as 1879, we have thought it sufficiently interesting to place before our readers for various reasons. In the first place, very little has been heard in England respecting the performance of the Jaspar system; and this, in connection with the mirrors and reflectors employed for equalising the light throughout large rooms, and the manner in which it was performed will, we feel sure, form a theme of general interest. In addition to the admirable way in which the lamps were disposed for the particular purpose assigned to them, the whole arrangement of the installation was carried out in a more minute and exhaustive manner than we remember to have seen either previously or since. Not a single point seems to have been omitted, and the experiment has more than a local significance as far as arc lamps are concerned, and the best carbons for employment therein. The nearest approach to the method of lighting adopted in the Jaspar system has been shown experimentally on several occasions, by Messrs. Siemens Brothers, who have thrown their light upwards, and thus allowed it to be reflected from the ceiling, or from suitably arranged reflectors, over a large space. But it is to the peculiar and ingenious arrangements of the mirrors and reflectors in the North Brussels Telegraph Office that we would call attention, for the large amount of light given by an arc lamp is there utilised to the greatest extent. As generally employed there is an enormous waste of light, and this matter has not yet been handled with a view of eliminating such loss. It has always appeared an odd thing, that after producing a certain intensity of light by means of a given current strength, we should at once reduce it one-half at least by enclosing the lamp in a thick opal glass globe. This may be perhaps essential in street lighting, but for factories and warehouses, it seems that such a device as that used at North Brussels might be profitably employed in England.

THE ELECTRIC NEWS-TELEGRAPH COMPANY.

UNDER the above title a new company has lately been brought before the public, which practically proposes to work in competition with the already established and well-known Exchange Telegraph Company. The latter, seeing that the base on which they stand is likely to be somewhat shaken, and the monopoly which they have hitherto enjoyed curtailed, seem to be doing their best to throw discredit upon the operations of their antagonist. The chief advantage which the new comers put forward as regards the instruments they intend to use is, that the apparatus only requires one wire to work it. The prospectus states that the apparatus "is remarkable for its simplicity, and is thoroughly reliable in action, the whole of its varied movements being regulated by one single wire. . . . The apparatus itself, which is small (and is almost silent in action), is fixed under a glass cover on a stand in the room or office of the subscriber, and by means of a paper tape contained within the machine, the news transmitted is printed in ink in large and legible characters upon the tape, both in words and in figures, without the intervention of any person whatever. . . . ." The machines have not any contact points, and are believed to be worked with some 60 per cent. less battery power than any existing instrument employed for a similar purpose. In a letter from Sir Charles Bright, the latter says: "The apparatus comprises several technical improvements of a novel and very ingenious character, one of which is a peculiar self-adjusting appliance by which the mechanism is brought into perfect unison at short intervals, precluding irregularity in working." This unison-adjuster, although referred to in the letter of Sir Charles Bright, is not claimed in the prospectus as one of the advantages of the system.

The Exchange Telegraph Company, in an advertisement

which they put forward, almost simultaneously with the issue of the prospectus of the new company, imply that this adjuster is put forward as one of the advantages of the new apparatus, and, moreover, they state that it is an infringement of a patent which is their own property. The Exchange Company further state that "they consider it an error to say that the whole of the varied movements of the instrument in question are regulated by a single wire, as they are partly dependent upon clockwork." They also say: "They have had in operation in London an electrical type-printing instrument for ten years, and although two wires are used for the purpose of giving quotations, this plan has been adhered to by them, and is universally used in America as being admittedly the best for recording the prices of stocks and shares." "The Exchange Telegraph Company have had for the same number of years more than one description of single wire type-printing instrument, with double the speed of any other single wire instrument in this country." The fact that a two-wire instrument has hitherto been considered to be better than one which works with one wire is, we think, hardly an argument that an equally good apparatus with one wire cannot be obtained, and the statement of the Exchange Company seems to imply that the apparatus which they used cannot be improved upon, except perhaps by themselves. The unison-adjuster is such an old idea comparatively that its protection by recent patents is, we think, open to question, unless the arrangement be a very special one, which, we rather fancy, is not the case in the Electric News Company's instrument. The use of clockwork, which enables the working battery power to be considerably relieved, is, in our opinion, no objection, but rather an advantage. We can hardly see by what argument the Exchange Company can say that the clockwork effects the "regulation" of the instrument; the clockwork is regulated, but it does not regulate. From opportunities we have had of seeing the working of the new instruments, we can testify to their efficiency, and to their compact form. The instruments of the Exchange Company, we know, are very efficient, but we cannot agree that their efficiency is so great, and that of the new company so small, as to render the use of the latter undesirable. The Exchange Company, feeling the pressure put upon them, and that their monopoly is slipping away from them, are naturally making every effort to prevent competition; but we doubt whether the statements which they have put forward will help them to any material extent.

CORRESPONDENCE.

TO CORRESPONDENTS.

No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer, not necessarily for publication, but as a guarantee of good faith.

Correspondence should arrive not later than Tuesday morning if it is desired to appear in the following number.

DYNAMO-ELECTRIC MACHINES.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Mr. Riley's letter in your issue of July 1st, taken in the face of your footnote, hardly calls for an answer from me. Perhaps, however, Mr. Riley's mind may be set at rest if I tell him that neither I nor any other patentee can have any right or claim to the outward shape or form of the field electro-magnets of a dynamo machine.

As this appears to be the only point in which Mr. Riley claims any resemblance between the two machines, I trust that this explanation on my part may satisfy his *amour propre*. I am, Sirs,

Your obedient servant,

HENRY F. JOEL.

July 5th, 1882.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—I have read the letter of your correspondent, Mr. J. S. Riley, in your issue of the 1st inst., in which he claims some similarity between his magneto-electric machine and that of Mr. Joel, and alleges that he showed me a photograph of his form early last year.

On looking over the visitors' book I find that a Mr. Riley visited the Library several times last year, and it is possible he may have shown me the photograph he refers to, but I am quite unable to say what were the principal features of his machine, or whether there is any similarity between it and the one to which it refers. I am not acquainted with either. Your note appended to Mr. Riley's letter renders any further remarks from me unnecessary.

I would add, however, that if Mr. Riley will examine the specifications of the principal dynamo-electric machines he will find *many* instances in which one machine is similar to another. I am, faithfully yours,

A. J. FROST,

Librarian, Society of Telegraph Engineers and of Electricians.

July 3rd, 1882.

NOTES.

THE ELECTRIC LIGHT IN THE CITY.—A considerable amount of correspondence is to be found on the subject of electric lighting in the *City Press* of Saturday last. The first is a lengthy and important letter from Mr. Alexander Peebles, in which he analyses the three lowest tenders received for each district to be illuminated. This gentleman bases his facts upon the report of the Commissioners of Sewers, the items of which appeared in the above paper in its issue of June 21st. (See ELEC. REV., June 24th.) There it was stated that the minimum charge for electric lighting in the four districts (three new, and the one vacated by Messrs. Siemens Bros.) was £9,930, as against gas £1,867 for the same area. This comparative estimate Mr. Peebles says is upon a wrong basis; hence his letter. In his tables the following data occur:—

District No. 1, comprising Newgate Street, Giltspur Street, Smithfield (S.E. and N.E. sides), Long Lane, Aldersgate Street (from Barbican to St. Martin's-le-Grand), and St. Martin's-le-Grand.—For lighting this district by electricity eight tenders were received, the three lowest being as follows: 6th, 1¾ per cent. more than gas; 7th, fully 5 per cent. less than gas; 8th, nearly 10 per cent. less than gas.

District No. 2, comprising Threadneedle Street (from front of Royal Exchange to Old Broad Street), Old Broad Street, New Broad Street (from Liverpool Street to London Wall), Liverpool Street (from New Broad Street to Bishopsgate Street), Bishopsgate Street (from Liverpool Street to Cornhill), and Cornhill.—For lighting this district by electricity seven tenders were received, the three lowest being as follows: 5th, fully 54 per cent. more than gas; 6th, fully 11 per cent. more than gas; 7th, fully 9 per cent. more than gas.

District No. 3, comprising Leadenhall Street, Aldgate, Aldgate High Street, Fenchurch Street, and Lombard Street.—For lighting this district by electricity seven tenders were received, the three lowest being as follows: 5th, fully 64 per cent. more than gas; 6th, fully 14 per cent. more than gas; 7th, fully 11 per cent. more than gas.

District No. 4, vacated by Messrs. Siemens Bros.—For lighting this district by electricity seven tenders were received, the three lowest being as follows: 5th, 17½ per cent. more than gas; 6th, 1¼ per cent. more than gas; 7th, 3¼ per cent. less than gas.

Upon adding together the estimated annual cost of the present gas light in these districts, it amounts to £1,867, whilst the four lowest tenders for the electric light amount to £1,863, but in this comparison gas has had the advantage of all the improvements in its manufacture which have been discovered since its introduction, and it is generally understood the gas companies do not regard street lighting as a source of profit, whilst electric lighting is, comparatively speaking, in its infancy, and in these tenders street lighting is alone included.

A second letter, by an anonymous contributor, relates to the apparent irregularity of prices charged for each district during last year's experiments, whilst a third emanates from W. J. Elliott, the gentleman who, on the strength of having tried to fire a gun by electricity, gives it as his opinion that the system of division and subdivision of the electric light as exemplified in the installation of Mr. J. B. Rogers is the best before the public.

In connection with the subject of private lighting we read in the *City Press* of Wednesday that at Tuesday's meeting of the Commission of Sewers—

The Clerk (Mr. Blake) read a petition from the Electric Light and Power Generator Company, and the Hammond Electric Light and Power Supply Company (Limited) stating: "That in tendering to

your Commission your petitioners have estimated that the lighting of the streets would be for one year only, and experimental in its character, and your petitioners have therefore been obliged to take into account that part of their plant and materials would be useless at the expiration of the year; but if your honourable Court see fit to give the light some permanency of character your petitioners would be able to make a lower tender. Your petitioners desire to point out that so far as regards the lighting of shops and warehouses they could do so by means of running cables into the shops and warehouses from the street. Your petitioners also desire to point out to the Commission that the lighting of shops and warehouses of private persons is a most remunerative undertaking, and if your Commission think fit to give to your petitioners and to the ratepayers the right of coming to an agreement with reference to private lighting *en route* your petitioners would be in a position to make a tender very much lower than they have hitherto been able to do." Mr. F. Green moved that the petition be referred to the Streets Committee, which was agreed to. A letter from the Pilsen Company to the same effect, and a petition from City merchants and traders, asking that the subject of private lighting by electricity might be speedily settled, were also referred to the Streets Committee for consideration and report.

"TRUTH" AND THE ELECTRIC LIGHT.—Of late a number of scathing, not to say worse, articles have appeared in *Truth* on electric light companies, chiefly attacking the Brush Company and the Sellon-Volckmar accumulator affair. An extract from the columns of this journal of June 29th reads as follows:—"The Brush Company, the most prolific and the most impudent of these companies, has for its vice-chairman Mr. Sellon, who, it has been proved, sold an utterly valueless 'patent' to a company for £340,000, and Sir Henry Tyler, who apparently makes a business by directorships, is its chairman." We think it is really time that these two gentlemen should take steps to defend themselves from these attacks, for the reputation of those associated with them, if not for their own sakes.

ELECTRIC LIGHT PATENTS.—We read in *Truth* that "not one vestige of evidence is adduced of the commercial value of the so-called patents." We do not quite see how the progress of electric lighting during the past four years could have so far advanced as we now see it in the present day had not the various patents taken out during this period presented some advantages over that which was public property anterior to these inventions. Surely if a man produces some *actual* improvement on what is known, and which improvement would by its adoption have a beneficial effect on any given system of electric light, he is entitled to some substantial reward as the result of his mental labour? If then any company can see that its operations will be assisted by the employment of something for which a certain sum is asked, it seems evident that the "something" has a commercial value. We will say, however, that sums have been paid utterly out of proportion to the actual value of the invention; but that does not seem to be the point at which *Truth* is aiming.

THE FYFE-MAIN ARC LAMP.—We hear on good authority that in addition to the six lamps already in operation at the new offices of the *Daily Telegraph*—and which, we are informed, give great satisfaction—Mr. Alexander Fyfe is busily employed in fitting up six more in the printing rooms, and that he will extend the system as far as his motive-power will allow, the engine at present supplying the driving power for the dynamo-electric machines being one by Marshall and of 10 horse-power nominal.

ELECTRICIAN WANTED.—We beg to call the attention of electricians to such advertisements, in case they might pass them by when first perusing our columns.

ELECTRICAL APPOINTMENT.—We are informed that Mr. A. F. A. Hervey, late assistant to Messrs. Woodhouse & Rawson, engineers and electric light contractors, has received the appointment of engineer to the Australasian Electric Light Company (Brush system), and he leaves on the 13th inst. for Australia. Mr. Hervey has the advantage of having made the subject his profession, and as he was for a number of years employed in India with the late Mr. Louis Schwendler, he has met with more than ordinary opportunities of acquiring knowledge in all branches of electrical science. We believe for the first eight months or so Mr. Hervey will be travelling through Australia and New Zealand with Sir Julius Vogel before beginning his practical work.

PERSONAL.—We believe that Mr. A. Le Neve Foster, who has been so long connected with the India-rubber, Gutta-percha, and Telegraph Works Company, of Silvertown, as chief of the instrument department, has now left that company and associated himself with a manufacturing company carrying on operations in the country. Mr. Foster is so well known amongst electricians that it is hardly necessary for us to say that anything he undertakes will be entered into with a thoroughness, and a knowledge of every part of his profession which will leave nothing to be desired. We shall be glad to hear of Mr. Foster's success in the future.

THE POST-OFFICE AND THE TELEPHONE.—It is brought to us on reliable authority that the Postmaster-General contemplates giving up the erection of private telephone lines, and as far as exchanges are concerned, the Post-office authorities will not interfere as long as their own interests are not invaded. It appears from this, therefore, that telephone exchanges, with but few exceptions, will soon be thrown open to all. Should this be true, a great impetus will be given to telephony, which is, comparatively, now almost at a standstill, albeit the telephone is the most wonderful invention of the age.

THE LONDON AND GLOBE TELEPHONE COMPANY.—Referring to the above note, it will be within the memory of our readers, that this company applied some time since for licences to open exchanges in many towns in England, amounting altogether, we believe, to some 160 or thereabouts.

TELEPHONIC COMMUNICATION WITH A CONGREGATIONAL CHURCH.—Telephonic communication (says the *Greenock Telegraph*) was on Sunday established between the residence of Mr. John M. Hutcheson, Thorndean, and the George Square Congregational Church, Greenock. The experiment was an entire success. Several persons in the Exchange, at Watt Place, heard the whole service quite distinctly, and even at Glasgow some passages of the Rev. J. M. Jarvie's remarks were written down and repeated to the people in the Greenock office, to show how clearly the sermon had been heard so far away. Mr. Hutcheson himself says that he did not miss a single word of the forenoon service, and that the musical part of the service was particularly well heard by him.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY'S CABLES.—We read the following in the *Panama Star and Herald* of June 8th:—

The cable of the West Coast of America Telegraph Company, from Mollendo to Chorillos, was successfully repaired in the early part of May, by their engineer, Mr. E. W. Parsoné, in the ss. *Retriever*. The break was off Point Pescadero, in about 800 fathoms of water. At that depth it was recovered with difficulty, rendered all the more so by a very singular circumstance. The country near the situation of the fractures, some 400 nautical miles or more South of Chorillos, is as barren of all kinds of vegetation, trees, or shrubs, as any part of the coast of Peru.

Notwithstanding this, the cable when raised to the surface, brought up great masses, tons in weight, of trunks, roots, and branches, apparently of well-grown olive and other trees. Here is a chance for some of our *savants* to tell whence came these trees, branches, roots, &c., so far from the shore, and in water nearly a mile deep. It cannot be accounted for by a submersion of any portion of the coast of Peru in any times known to history, since we have no such record. Nor have any notable land slides occurred by which such ligneous growths could have been swept from the land into the sea, to be imprisoned at its depths by the earth or portions of rocks still clinging to them. Probably in times of which history or Indian tradition make no note, in some convulsion of nature on that coast, so frequently stricken by earthquake or tidal wave, that portion of the coast was submerged and carried with it to the depths of the sea, the human beings who inhabited its lands, their dwellings, and their wealth, and the gardens and orchards they cultivated. At the depth at which these curiosities were found, decay would scarcely affect them.

THE POST-OFFICE CABLES.—The Post-office authorities have again chartered the London and Edinburgh Shipping Company's steamer *Morna* for the purpose of repairing their faulty cables in Shetland, and on the West Coast of Scotland.

TELEGRAPH CABLES.—In the House of Commons on Tuesday last Mr. Monk asked the Under-Secretary for Foreign Affairs whether Her Majesty's Government had

taken any steps, in concert with other nations, with a view to the protection and preservation of telegraph cables, and whether it was proposed to send a representative from this country to the conference of European maritime countries to be held in the autumn? In reply, Sir Charles Dilke said Her Majesty's Government accepted an invitation from the French Government to take part in a conference on this subject, which was to have met at Paris on the 1st of last month. The French Government, however, postponed its meeting until the autumn. Her Majesty's Government are of opinion that advantage might be taken of this delay to settle beforehand the scope of the labours of the conference. They are at present in communication with the French and other Governments concerned, and if an understanding is arrived at on this point they will be represented at the conference.

UNDERGROUND CABLES IN GERMANY.—A commencement has been made in Strasburg with the laying of the underground cables intended to replace the overhead wires, which start from the Telegraph Office of the Quai de Paris, some in the direction of the covered bridges and others in a parallel direction to the Faubourg de Saverne. The cables are laid in a trench, about one metre deep (3·28 ft.), which from the building of the central telegraph office, passes over the Bridge de Saverne, under the footpath on the right, and then along the right side of the Faubourg de Saverne, as far as the embankment of the new railway station. In this trench four cables will be laid, each composed of seven telegraph wires for the lines to Paris, Weisenburg, Lauterburg, &c. A second trench starting as well from the Quai de Paris and following the left side of the Quai de Saverne, will be dug along the Quai Saint Jean, through the large street de la Course, as far as the central railway station, and in this trench six cables will be laid, each composed of seven telegraph wires, and intended for the traffic over the lines to Basle, Kehl, Molsheim, &c. One of the cables will be laid in the Küss street, in order to establish a direct communication between the central railway station and the telegraph office of the Quai de Paris. The cables then follow the different lines which start from the new central railway station, and are continued till outside the new fortifications, when the telegraph wires become again overhead wires.—*La Lumière Electrique.*

THE BONE-BISERTE CABLE.—The French Government telegraph steamer *Charente* started laying this cable from Bone, on the 21st ult., and we read in the *Petit Marseillais*, of the 28th ult., the following:—"The laying of the submarine telegraph cable between Bone and Biserte has been successfully completed last night. The cable between La Calle and Biserte will be worked as before, to relieve the traffic. Another Director of Posts and Telegraphs, M. Cayler, is expected, to replace M. Rubichon, who is allowed to retire on a pension. It has been found necessary to re-arrange the Tunisian telegraph staff owing to the great devolopment of that service with Tunis."

MEXICAN CABLES EXTENSION.—The ss. *G. E. Wood*, chartered by the India-rubber, Gutta-percha, and Telegraph Works Company for the Mexican Cables Extension safely returned from Mexico on Monday the 3rd inst. She is now discharging, off the Silvertown Works, the cable stores, machinery, tanks, &c., with which she was fitted for that expedition.

THE CABLE SHIP "CAROLINE."—The ss. *Caroline*, chartered for the repairs of the Otranto-Corfu cable, left Messrs. W. T. Henley & Co.'s Works on the 28th ult. We understood that Mr. W. A. Killingbeck went out in charge of the cable staff, but this is not confirmed.

SUBMARINE TELEGRAPHY.—We extract the following from the *Times*, concerning Mr. Jacob Brett and the invention of submarine cables. A correspondent writes:—

Mr. John Watkins Brett and his brother, Mr. Jacob Brett, may unquestionably be designated as the original projectors (if not inventors) of the Submarine Telegraph, for as far back as July, 1845, the Messrs. Brett registered their plan for an oceanic or submarine telegraph, and in the same year took out patents for the construction of subterranean lines. In 1847 they obtained permission from the Government of Louis Philippe to establish a submarine cable between the coasts of France and England, but were unable to obtain any support from the public to carry out the undertaking. In 1849 a concession for the same object was granted to them by Prince Louis Napoleon, then President of the French Republic, and in 1851 the Submarine Telegraph Company was formed, and a substantial cable containing four conducting wires, and protected by a coating of strong iron wires, was laid between Dover and Sangatte, near Calais, and this cable is at the present moment in excellent working condition. Mr. John Watkins Brett became afterwards one of the founders of the Atlantic Telegraph, and also of various telegraph lines in the Mediterranean. He died in 1863, leaving only a moderate fortune to be divided among a numerous family of brothers and sisters. Since that time Mr. Jacob Brett, who is now seventy-four years of age, has fallen into most serious pecuniary difficulties, and at the present moment is absolutely without a home or any means of supporting himself. A committee, consisting of Sir James Carmichael, Chairman of the Submarine Telegraph Company, and other gentlemen interested in telegraphic enterprise, has therefore been constituted to promote the subscription of a fund in aid of Mr. Jacob Brett, to which the Submarine Company have given £200, and an appeal is confidently made on his behalf for further assistance to those companies and individuals, as well as to the public in general, who have derived such great benefits from the establishment of the Submarine Telegraph. It must be remembered that if the earlier experiments of Messrs. Brett had ended in failure, the world might have been long deprived of that invention which Lord Granville has so happily termed "the wonderful instrument of communication of thought."

Sir J. R. Carmichael writes from 2, Throgmorton Avenue, London, E.C., July 1st:—

With reference to a communication respecting "Submarine Telegraphy," which is published in the *Times* of to-day, may I be permitted to add that Messrs. Ransom, Bouverie, and Co., of 1, Pall Mall East, have kindly consented to receive any subscription to the "Benefit Fund" in aid of Mr. Jacob Brett, which is alluded to by your correspondent.

TELEGRAPHS IN CHILI.—The *Chilian Times*, of May 13, says:—

The improvement and extension of the State telegraph system is under the consideration of the Government. In a report of the 2nd inst. the Director-General of Telegraphs recommends the establishment of offices at Pena Blanca, Paiguano, Tongoy, Panulcillo, Palmilla, Matanzas, San Antonio de las Bodegas, Llico, Vichuguen, Curepto, Florida, Curanipe, and Castro, the last-mentioned place being on Chiloe Island. The estimated cost of the extensions is a little over 74,000 dollars. The director also points out the necessity of laying an additional wire from Iquique to Canete, the present line being totally inadequate to meet the requirements of the public. If the proposed extensions should be carried out, and we presume they will be, the total length of the State telegraph lines will be 14,265 kilometres.

LAUNCH.—On the afternoon of Thursday, the 29th ult., Messrs. John Elder and Co. launched, from their Fairfield Works, Glasgow, the steel paddle-ship *Normandy*, constructed by them for the London, Brighton, and South Coast Railway Company, and the Western of France Railway Company. The *Normandy* is similar to, though somewhat larger than, the *Victoria* and the *Brighton*, owned by these companies. She will be very handsomely fitted for 100 first-class and seventy second-class passengers, and every convenience necessary for the channel passage, including electric bells and the electric light, will be provided.

MAGNETIC OBSERVATIONS AT THE PARIS OBSERVATORY.—We are glad to learn that owing to the exertions of Admiral Mouchez magnetical observations will soon be resumed at the Paris Observatory in subterranean chambers, which have been excavated in the newly annexed ground. These observations will be self-registering by photography, in conformity with the instruments established by M. Mascart at the Collége de France. Direct observations will also be taken with the old instruments, which were used by Arago, who was famous for his prognostications of auroræ at a period when, the electric telegraph not having been invented, many days must elapse before the arrival in Paris of news from the northern parts of Europe.

ON THE CHEMICAL WORK PRODUCED BY THE BATTERY.—By M. D. Tommasi.—Joule and Favre have shown that the power of the galvanic battery has a close relation with the heat which the chemical reactions in the battery itself produce. An entire order of questions respecting currents may be treated as calorimetric problems. The electromotive force of a battery is proportional to the heat evolved by chemical action, and thus if we know the number of calories dis-

engaged by such action we may arrive at the work which the battery is capable of performing. Favre, however, has pointed out that the heat brought into play during the combustion of the hydrogen in electrolysis is transmitted or not transmitted to the circuit according to the nature of the compound which furnishes the oxygen necessary for such combustion.

Thus, *e.g.*, of 131 cal. evolved by an element with oxygenated water and hydrochloric acid, there are merely 41·6 cal. which are transmitted to the circuit, and which consequently represent the energy of the battery. Favre observed, further, that in the sulphatation of the zinc of a simple element (zinc, platinum, and acidulated water), 39 cal. are brought into action; but of this number 29·8 cal. only are transmitted to the circuit, whilst 9 cal. remain in the interior of the battery.

I will first examine this latter case, as being the most simple, and will treat afterwards of the calories evolved in elements with two liquids.

1st. A zinc-platinum element with dilute sulphuric acid (Smee's battery) evolves, according to Favre, 39 cal.; but of this number there are only 29·8 cal. transmitted to the circuit, and representing the energy of the battery. It would then follow that two such elements could not decompose water. In fact,

$$29{\cdot}8 \text{ cal.} + 29{\cdot}8 \text{ cal.} < 69 \text{ cal.}$$

But I have shown that the decomposition of water takes place conformably with what might have been expected if all the calories disengaged by the two elements had been transmitted to the circuit. Thus,

39 cal. + 39 cal. > 69 cal. (Favre), or 38 cal. + 38 cal. + 1 cal. > 69 cal. (calculated from the most recent thermic data).

If the water of the voltameter is acidulated with hydrochloric acid the decomposition of the water is facilitated, as might be foreseen, knowing that the electrolysis of dilute hydrochloric acid absorbs per two molecules merely 66 cal., in place of 69. But even in this case there should be, according to Favre, no electrolysis, since 29·8 cal. + 29·8 cal. < 66 cal.

If, in the preceding elements, we substitute for the two platinums two plates of graphite previously heated to redness, which ought not, according to received ideas, to modify the chemical action of the battery, the decomposition becomes very brisk. But if we use electrodes of coke with a large surface the decomposition of the water is, beyond comparison, more energetic.

2. According to Favre, two zinc-platinum elements with dilute hydrochloric acid ought not to decompose water if acidulated with sulphuric acid, but should decompose it if acidulated with hydrochloric acid. In the former case we should have—

$$33{\cdot}4 \text{ cal.} + 33{\cdot}4 \text{ cal.} > 69 \text{ cal.; but in the second—}$$

33·4 cal. + 33·4 cal. < 69 cal. In fact, two such couples do not decompose water if acidulated with sulphuric acid, but the decomposition ensues if the water is rendered acid with hydrochloric acid. Two zinc-graphite elements, or preferably two zinc-coke elements, decompose briskly water acidulated with sulphuric acid. It is the same if we use a zinc-carbon element along with a zinc-platinum, though in this latter case the action is more feeble. In either case the decomposition cannot be explained according to Favre, but it is intelligible on thermic principles. 34·2 cal. + 34·2 cal. + 1 cal. > 69 cal.

3. A zinc-platinum element in dilute hydrobromic acid ought to develop according to Favre, 35·9 cal., of which only 29·9 are transmissible to the circuit. Consequently two such elements ought not to decompose water acidulated either with sulphuric or hydrochloric acid; if the water of the voltameter is acidulated with sulphuric acid, we observe a beginning of decomposition, which soon comes to an end. The decomposition of water is more marked with a zinc-graphite and a zinc-platinum element, and better still with two zinc-graphites. It is most energetic with two zinc-coke elements. If the water of the voltameter is acidulated with hydrobromic acid there is also electrolysis; but it is not the water which is decomposed, but the hydrobromic acid itself. Whatever the degree of dilution of this acid, we always see an escape of gas at the negative electrode; whilst at the positive electrode there is no escape of gas, but a yellowish thread of bromine is formed round the platinum wire. This fact is easily explained, since 2 molecules of hydrobromic acid absorb 59 cal. for their decomposition, whilst 1 molecule water absorbs 69 cal.; so it is always the compound which absorbs least heat, which is decomposed in preference by the current, as the author showed in 1879.—*Comptes Rendus.*

ON THE INFLUENCE OF THE POSITIVE ELECTRODE OF THE BATTERY UPON ITS CHEMICAL WORK.—By M. D. Tommasi.—In my researches upon electrolysis I have ascertained the singular fact that the electromotive force of one and the same couple may vary according as the positive electrode is of platinum or of coke. An element, *e.g.*, which is incapable of effecting the electrolysis of water or a saline solution, although the calories which it disengages are greater than the calories absorbed by the decomposition of the electrolyte, if its positive electrode is of platinum, becomes able to produce such a decomposition if its positive electrode is of coke. As this fact is of great importance as regards the relation which I am seeking to establish between the calories liberated by the battery and the calories absorbed by the decomposition of the electrolyte, I have examined it in some detail, and have made the following observations:—

A magnesium platinum couple in dilute sulphuric acid ought, according to thermic data, to decompose water; the number of calories liberated by the action of magnesium upon dilute sulphuric acid (112) is greater than the number of calories of the decomposition of water (69). Nevertheless, the decomposition does not take place. It is the same if we substitute copper or silver for the platinum of the element, but if we use as a positive electrode a cylinder of graphite or of coke, the electrolysis of the water takes place.

According to M. Berthelot, two zinc-platinum elements with dilute sulphuric acid do not decompose a solution of sulphate of potash. But on employing two zinc-carbon elements with dilute sulphuric acid, I have been able to electrolyse a saturated solution of sulphate of potash with a copious liberation of gas at the two platinum electrodes, and a transfer of the acid to the positive electrode and of the base to the negative electrode, and this in the lapse of a few minutes and at the common temperature. There are required, according to M. Berthelot, at least 103 cal. to electrolyse a solution of sulphate of potash, whilst I obtain this same decomposition with 76 cal. and even fewer, for it is produced with two zinc-carbon elements and dilute hydrochloric acid, say with 69·8 cal. (calories disengaged by the action of a molecule of amalgamated zinc upon dilute hydrochloric acid). A single zinc-coke element with dilute sulphuric acid decomposes sulphate of potash if the electrode of the voltameter is of copper, but not if the electrode is of silver.

I have submitted various salts to electrolysis. The conditions of the experiments are as follows:—The saline solutions contained an excess of salt. The platinum wires of the voltameter were 0·4 mm. in diameter, and plunged into the liquid to a depth of 0·3 to 0·4 metre. The carbons employed were Siberian graphite or gas-coke previously heated to redness and cooled in a stoppered bottle containing air, nitrogen, and by preference, carbonic acid. To obtain good results, the coke or the graphite should remain at least six hours in contact with carbonic acid. The presence of this gas in the pores of the coke has no other object than to retard the polarisation, rendering consequently the effects more intense and giving them a longer duration. Two zinc-carbon elements with dilute sulphuric acid (= 77·4 cal.) decompose the following saline solutions:—Sulphates of magnesia, zinc, cadmium, copper, manganese, iron, chloride, bromide, and iodide of potassium.—*Comptes Rendus.*

OBSERVATIONS ON ELECTRIC FISHES.—By Herr G. Fritsch.—The author during a sojourn in Egypt has made a series of anatomical and physiological observations on *Malopterurus electricus*. He has also confirmed the suggestion of Babuchin that *Mormyrus* also is an electrical fish. From a very lively specimen of *Mormyrus oxyrhinchus*, 165 millimetres in length, he obtained in two and a half hours twelve electric discharges. This small fish did not

live long, and the author did not possess the apparatus necessary for determining the direction of the discharge. As, however, the genus *Mormyrus* is rich in species, now their electric properties are recognised it will not be difficult to study them more closely.—*Du Bois Reymond's Archiv.*

On the Dispersive Power of Electricity.—By L. Palmieri.—If the bifilar electrometer of Palmieri receives either a positive or a negative charge the losses of electricity in a space protected from currents of air are in equal times rather greater for a negative charge than for a positive. The differences are greater in dry weather, and disappear in very moist air.—*Wiedemann's Beiblätter.*

Means of Rendering the Holtz Machine more Active.—By C. Marangoni.—The discs are freed from varnish, steeped in distilled water for twenty-four hours, set to dry in a vertical position without touching anything, and re-introduced into machine. It acts then again for some time in a protective case. The discs, therefore, are not to be varnished. The machines are excited by a gutta-percha plate better than by ebonite.—*Wiedemann's Beiblätter.*

The Electric Tensions between a Metal and Liquids of Different Concentration.—By Erasmus Kittler.—The author has made a long series of determinations of the differences of tension of certain chlorides in various combinations. The results are here given, our readers being referred to the original for the details of the observations.

If in the combination : copper | solution + solution | copper sulphate + copper sulphate | copper, there are substituted successively the concentrated aqueous solution of chlorides of potassium, sodium, ammonium, lithium, calcium, strontium, barium, magnesium, manganese, and nickel, there are obtained on using a dilute solution of sulphate of copper (0·6 parts to 100 of water) the following electromotive forces: chloride of ammonium = 0·318 Daniell; chloride of potassium = 0·315 D.; chloride of lithium = 0·308 D.; chloride of calcium = 0·304 D.; chloride of sodium = 0·302 D.; chloride of strontium = 0·290 D.; chloride of magnesium = 0·275 D.; chloride of barium = 0·251 D.; chloride of manganese = 0·247 D.; chloride of nickel = 0·231 D. The series in which these chlorides fall remains the same if distilled water is used instead of solution of sulphate of copper.

If dilutions of these chlorides are used instead of saturated solutions the electromotive force of the elements decreases with the proportion of the salt in the solution, whether in presence of sulphate of copper or of distilled water. The influence of the concentration of the chlorides upon the electromotive force is very considerable. The difference is greatest with chloride of ammonium, and smallest with chloride of sodium.

The arrangement : copper | $L_1 + L_1$ | $L_2 + L_2$ | copper, in which L_1 and L_2 represent saline solutions of different degrees of concentration, give a current in the direction from L_1 to L_2. The current consequently passes from the chloride to the sulphate of copper, or to water, and from the more concentrated to the more dilute solution.

Volta's law of tension holds good for solutions of the above chlorides of different strengths in contact with distilled water, and a solution of sulphate of copper.

The combination : copper | solution + solution | sulphuric acid + sulphuric acid | copper, yields for the saturated solutions of the chlorides above mentioned a different series than the above combination with sulphate of copper. Here chloride of calcium gives the greatest electromotive force = 0·335 D.; then follows chloride of strontium = 0·334 D.; chloride of lithium = 0·323 D.; chloride of magnesium = 0·321 D.; chloride of manganese = 0·294 D.; chloride of ammonium = 0·283 D.; chloride of sodium = 0·287 D.; chloride of nickel = 0·265 D.; chloride of barium = 0·254 D.

Here also the electromotive force decreases with the proportion of salt in the solution, but the influence of the degree of concentration is here more prominent than in the former combinations. The current passes in this combination from the chloride to the acid, but if very dilute solutions are used, from the acid to the chloride or to water; the v of tension does not hold good for the chlorides in contact with dilute sulphuric acid. The electromotive force of the liquid combination : sulphate of copper | solution + solution | sulphuric acid + sulphuric acid | sulphate of copper, in which the members, sulphate of copper and sulphuric acid, remain constant, changes considerably with the proportion of saline matter in the solution—*Naturforscher & Annalen der Physik.*

On the Law according to which the Electromotive Force of a Magneto-electric Machine varies as a Function of the Resistance of the Exterior Circuit. —By M. Marcel Deprez.—The author, in his experiments on dynamo-electric machines, has been struck with the fact that the electromotive force developed in the ring of these machines not merely does not increase infinitely with the intensity of the current which traverses the inducing electro-magnets, but even decreases very notably, whilst the current produced increases more and more.

He has thus been led to think that the electromotive force developed in the ring of a magneto-electric machine, whose magnetic field is constituted by a permanent magnet, is not constant, as has been hitherto admitted, but is a function of the intensity of the current developed in the ring.

To verify this supposition, he has kept the magnetic field of a Gramme machine constant by exciting the inducers by means of an auxiliary source, and has examined how the electromotive force of the ring, turning at the same velocity, varies on closing the outer circuit with more and more feeble resistances. The experiments, given at length in the original memoir, show that the electromotive force developed on the ring decreases when the intensity of the current produced augments. They show also distinctly that the constant fall in the "characteristics," when the current produced becomes very intense, depends on the insufficiency of the inducers. These are, indeed, never too powerful, which is an additional argument in favour of large machines, as the author has demonstrated both theoretically and experimentally that a magnetic field of given intensity is the less expensive to obtain, as it is produced by electro-magnets of more considerable dimensions.

As for the cause of this phenomenon it may be explained as follows : suppose that the passage of the current is suppressed in the inducers and only let pass in the ring, the latter becomes a powerful magnet, the polar lines of which coincide with the diameter, which passes through the points of contact of the brushes and the collector.

If we invert the operation by suppressing the current which traverses the ring, and re-establishing that in the inducers, the polar line coincides with that of the inducers. Hence it results that when the current traverses at once the ring and the inducers, the line of the poles of the ring occupies a position intermediate between the two extreme positions just defined, and may even be determined by that of a construction analogous to that of the parallelogram of forces. It is easy to see, on applying this construction, that the polar line of the ring approaches so much the more to the line of contact of the brushes as the current traversing the ring is more intense, whilst the maximum difference of the potential between the two brushes corresponds, on the contrary, to the case where the polar line of the ring is perpendicular to the diameter, passing through the points of contact.

This amounts to saying that, in proportion as the intensity of the current traversing the magnetic ring increases, the wires of the ring intersect the lines of force of the magnetic field, comprised between the polar pieces and the ring at an angle which differs more and more from a right angle, which is, as is known, the angle corresponding to the maximum electromotive force.

The sole means of reducing within certain limits the defect inherent in all dynamo-electric machines consists in the use—

1st. Of very powerful inducers, surrounded with a moderate quantity of wire.

2nd. Of brushes of variable level.—*Comptes Rendus.*

Electric Fire Signal.—By M. Carré.—This apparatus consists essentially of an iron wire stretched by a spring which acts constantly, and when the wire is elongated in

consequence of a given rise of temperature, it closes an electric circuit in which there is an alarm-bell. The communication is established instantaneously by the rupture as well as by the expansion of the wire.—*Comptes Rendus.*

REMARKS ON THE USE OF ZINC-COKE ELEMENTS IN ELECTROLYSIS.—By R. Berthelot.—A zinc-coke element cannot be regarded as equivalent to a zinc-platinum element in calculating the quantities of heat set free by the reactions which give rise to the galvanic current. The heat disengaged by the attack of the zinc and the acid is not, in the case of coke, the only heat. The coke exerts in these conditions peculiar and complicated reactions. It absorbs hydrogen and oxygen, and intervenes both by the pure carbon which it contains and by the foreign matters mixed in its mass. This is shown by the researches of M. E. Becquerel ("Annales de Chimie et de Physique," 3rd Série, t. xlviii., p. 256) on the electro-motor of such elements. The author adds that the thermic values which express electrolytic reactions are only established for dilute liquids; the effects due to the separation of a trace of acid and of base in saturated saline solutions cannot be exactly calculated by reason of the changes of concentration and the secondary reactions. The principles of the calculation are the same, but the data are wanting.—*Comptes Rendus.*

OSCILLATIONS OF THE PLANE OF POLARISATION BY THE DISCHARGE OF A LEYDEN BATTERY. SIMULTANEITY OF THE ELECTRICAL AND OPTICAL PHENOMENA.—By MM. E. Bichat and R. Blondlot.—We have undertaken to study the rotation of the plane of polarisation in a transparent body under the action of the current of the discharge of a Leyden jar. The experiment was arranged in the following manner: between a polariser and an extinction analyser was placed the transparent body in a coil of long and thin wire, connected with the coatings of a battery. In the circuit was introduced a universal discharger, which permitted the discharge to be produced when the difference of potential is sufficient. At the moment of each discharge the eye placed before the analyser perceives a bright reappearance of light, which shows that the plane of polarisation has deviated.—*Comptes Rendus.*

REMARKS ON THE PRODUCTION OF LICHTENBERG'S FIGURES.—By K. L. Bauer.—For several years the author has in his physical class produced the Lichtenberg figures by dusting a smooth even plate of hard rubber (an electrophorus plate) with lycopodium, and then allowing a stream of sparks to pass upon the plate from the knob of a Kleist jar, charged either positively or negatively. This procedure, in which the two customary operations are performed in an inverted succession, may be recommended because, according to the author's experience, it gives fine, well-characterised figures with more certainty than that generally prescribed. Jars of different sizes may be used, on the rods of which conductive buttons of different size, shape, and material may be screwed or fixed. The conductive connection of the knob with the internal coating must remain when the jar is inverted, for the purpose of discharging, so that the rod with its knob is directed perpendicularly downwards. Hence the connection cannot be effected by means of metal chains. —*Annalen der Physik und Chemie.*

ON COLOURED SPARKS AND THEIR PRODUCTION BY INTERNAL AND EXTERNAL RESISTANCES.—By W. Holtz.—In Vol. iii., p. 626, of the *Beiblätter*, 1879, there appears a notice on the production of coloured sparks which are obtained by interposing semi-conductors between Leyden jars, or using semi-conductors as coatings for the jars themselves. I cannot refrain from pointing out that as far back as 1875 (*Pogg. Annalen*, Ergänzungsband vii., p. 520, 1875) I described at length the production of coloured sparks by external resistance. In 1877 (*Pogg. Annalen*, 160, p. 559, 1877) I showed that the same effect may be obtained by means of internal resistance. I did not remain satisfied with coating the jars with semi-conductors, but I filled the jars with imperfectly conductive liquids instead of an internal coating. Though I have latterly not recommended internal resistances for the above purpose, it is because external resistances are equally efficient and more convenient.—*Annalen der Physik und Chemie.*

NEW COMPANY REGISTERED.

PYRAMID ELECTRIC COMPANY (LIMITED).—Capital: £80,000, in £1 shares. Objects: To purchase for £6,000 in cash and £16,000 in fully paid deferred shares the electric inventions of William B. Brain and Radcliffe Ward, and the business carried on by the former under the style of the Electric Blasting Apparatus Company in the Forest of Dean, Gloucestershire. Signatories (who take one share): W. B. Brain, Cinderford; R. Ward (electrical engineer), 7, Northumberland Street, Strand; A. L. Foster, East Hill, Wandsworth; T. S. Collins, Ross, Hereford; R. Ferguson, 7, Oxford Terrace, W.; B. Le Neve Foster, East Hill, Wandsworth; C. W. Parkes, 11, Queen Victoria Street. Directing qualification: £300 of nominal capital. Remuneration: £21 for each meeting, to be divided as the directors may determine. Registered 29th ult. by Charles Doubble, 14, Serjeant's Inn, Fleet Street.

NEW PATENTS—1882.

3039. "Galvanic batteries." C. P. NEZERAUX. Dated June 28. (*Complete.*)

3042. "Incandescent electric lamps." F. L. WILLARD. Dated June 28.

3046. "An improved method of abstracting gold and silver from their ores, by the combined action of electricity and mercury." R. BARKER. Dated June 28.

3047. "Telephone receivers." W. SPENCE. (Communicated by M. Kotyra.) Dated June 28.

3048. "Insulating and protecting telegraph wires and other electrical conductors." G. MACAULAY-CRUIKSHANK. (Communicated by W. C. Banta.) Dated June 28.

3054. "Means or apparatus for regulating the production of electricity." J. C. MEWBURN. (Communicated by F. Rigaud.) Dated June 28.

3061. "Magnetic compasses." F. BETBEDER. (Communicated by E. Bourse.) Dated June 28.

3070. "Electric arc lamps." E. DE PASS. (Communicated by C. Roosevelt and B. Adbank *alias* Abakanowicz). Dated June 29.

3073. "Improvements in electric railways or tramways, and in means or appliances to be used in connection therewith, parts of which improvements are applicable to the propelling of vehicles on common roads by electromotive force." H. BINKS. Dated June 29.

3079. "Electric lamps." J. H. JOHNSON. (Communicated by L. BARDON.) Dated June 30.

3097. "Secondary batteries." A. WATT. Dated June 30.

3099. "Preparation of carbon filaments." A. R. LEASK and F. P. SMITH. Dated June 30.

3101. "An improved arc electric lamp." R. H. COURTENAY. Dated June 30.

3107. "Secondary batteries." C. H. CATHCART. Dated July 1.

3108. "Improvements in secondary batteries or magazines of electricity, and in apparatus connected therewith." H. J. HADDAN. (Communicated by C. F. Brush.) Dated July 1.

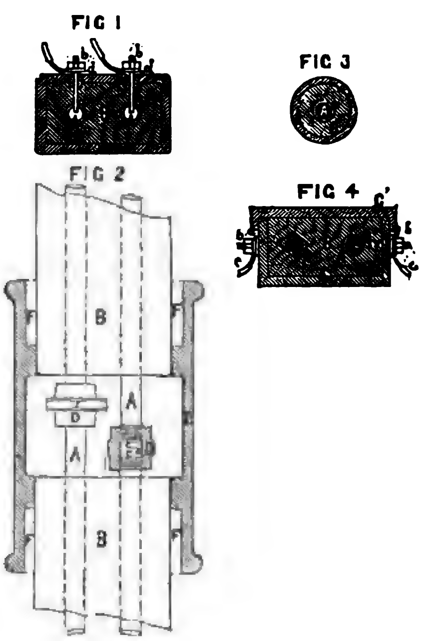
ABSTRACTS OF PUBLISHED SPECIFICATIONS, 1881.

5050. "Apparatus for automatically transmitting and receiving signals, &c." F. R. FRANCIS. Dated November 18. 6d. Relates to improvements in apparatus for automatically transmitting and receiving signals, for denoting places at which attempted burglar

and robberies may be made, and for other purposes, consists in the application, combination, and arrangement of a series of specially constructed commutators or contact makers, in number corresponding with the signals required, or with the rooms, doors, windows, safes, and other parts of buildings or things to which the commutators may be affixed in connection with insulated copper and galvanised iron, or other wires, for communication between buildings or things so fitted as aforesaid, and the nearest police or other stations, and arranged so that each commutator or contact maker is capable of producing one signal only, such signal being the name and number of the building, house, room, door, window, safe, or other thing so fitted, as before mentioned, with the commutators or contact makers, thus showing the precise locality of any attempted burglary or robbery.

5080. "Apparatus for the conduction and distribution of electric currents." R. E. B. CROMPTON. Dated November 21. 6d. The inventor constructs durable and economical insulated conductors, specially suitable among other things for use in electric lighting on a large scale in the following manner:—Copper rods are taken of proper thickness and their ends are enlarged by a suitable tool, and on these enlarged ends screw threads are cut. The ends are thus enlarged to preserve the effective section of the conductor from being reduced at the joint. The pitch of these screw threads is so taken that at each junction, when the rods are placed in the order in which they are to lie in forming the conductor, the screw threads on the two adjacent ends are of slightly different pitch. Over these ends is screwed a sleeve or socket. When this is screwed up in the proper direction it forces the ends of the conductors into very intimate contact. The screw threads on the extreme ends of the rods are stripped for a little distance to allow of the rods being so screwed together, or some other equivalent method is used. The conductors so formed are insulated by placing one or more of them in tubes of convenient section. These tubes will in general be made of cast iron for the sake of cheapness. The conductors may be, if desired, maintained in the proper position within the tubes during the process of insulation by core nails or chaplets, such as are used for the support of the cores of pipes when cast horizontally; the tubes are then placed containing the copper rods in a vertical position, and purified blast furnace slag is poured in so as to form a vitreous insulating envelope, thoroughly insulating and protecting



each of the conductors. To insure perfect and intimate contact between the conductors and their insulating envelope, it is preferred to enamel them before placing them in the tubes. After the process of running in the vitreous matter is complete, and it has become hard, the chaplets or core nails are removed. The holes left by them can be filled up with insulating material of any durable kind, and the hole in the tube closed by a screw plug if there is no desire to join a branch on to the main at that point. If however it is intended to bring out a branch from the main at that point, a copper plug of proper length is screwed into the metal of the conductor, and brought out through a porcelain or glass washer, or surround it with other suitable insulating material, so as to prevent it coming into electrical contact with the metal tubes or any other conductor in the tubes or the earth. The branch wires are connected to these copper studs preferably by baring a portion of the branch wire, and after stripping it of any insulating material that may be on it, taking a turn with it under the head of the copper plug before it is screwed down. The hole through which the branch connection is made may with advantage be covered by a cast iron hood or cap screwed down to the outer surface of the envelope, and finally filled with pitch, or gutta percha, or other suitable insulator to prevent the entrance of moisture. The insulating material should if possible be poured in in a fluid state through a hole in the cap, which should finally be secured by a screw plug. The tubes or cases above described in which the conductors are placed are joined by means of short tubes made to slip over and fit somewhat closely upon the adjacent ends of those containing the conductors, and these short tubes are joined to those over which they slip by ordinary gasket and run lead joints, such as are used in the case of cast iron water pipes, or it may be found convenient to use rubber packing, or rubber rings, or other well known modes of making such joints water tight, and at the same time not perfectly rigid, to allow for the movements caused by expansion, settlement of the ground, or other like causes. In the walls of these socket pipes holes are to be left, through which melted pitch or other suitable insulating material can be poured, so as to fill them up entirely after the joints above referred to have been securely made, and the holes are finally filled up with screw plugs. To enable these socket pipes to be used the conductors are made to project such a distance beyond the tubes that contain them as to enable the junctions to be most easily constructed. Fig. 1 shows a transverse section of a tube of cast iron or other suitable material containing two conductors, A, A, of copper enamelled, and these conductors, A, A, are imbedded in and insulated from each other and from the containing tube or case by means of the mass of slag or other suitable vitreous material, B, which fills the remaining space in such case. Where it is desired to bring out branches from the conductors, A, A, there are screwed into the conductors, A, A, copper plugs, *a*, *a*, passing such plugs through porcelain, glass, or other insulating washers, *d*, *d*, which are screwed or otherwise secured into the case, C, and to these plugs, *a*, *a*, are attached suitable connecting wires or leads, by means of the nuts, *b*, *b*, or other suitable connections. Fig. 2 shows by a longitudinal plan view, partly in section, an arrangement of parts adapted for connections of portions of tubes and their contained conductors, A, A. The end portions, e^1, e^2, of the conductors, A, A, are somewhat enlarged, and are formed with screw threads thereon, adjoining ends being as shown alternately formed with threads of finer pitch, e^2, and coarser pitch, e^1, and over these are passed and screwed correspondingly threaded socket pieces, D, D, which thereby hold these parts together. The conductors thence pass into and are embedded in the masses of slag, B, B, partly within the sleeve piece, E, and thence to within the tubes or cases, which are passed to within the spaces, F, of the piece, E, which serves to connect those part tubes. Fig. 3 shows a section of a single core or conductor, A, with its enamel covering, *e*, its insulating coating of slag, B, and containing metal tube, C, which tube may be conveniently formed of wrought iron. This arrangement will be found particularly convenient when two conductors are not required. Fig. 4 shows a section of another arrangement of parts somewhat similar to that shown by fig. 1, but more particularly adapted for being placed in the footways of roads. The like letters of reference indicate like parts, as in fig. 1, and the description thereof applies equally well to this arrangement, except that in this arrangement of tube or case, C, one side (the upper side as shown) is adapted for removal in the form of a lid, C^1, affording means of easy access to the rods or conductors and their insulating covering and the branch connections, and these branches, *b*, are applied from the side of the case, *c*. The covers, C^1, may be roughened or formed so as to afford good foothold.

5096. "Electrical commutators." W. R. LAKE. (A communication from abroad by Francis Blake, of America). Dated November 22. 6d. Consists in combining with a pile of plates of metal and hard india-rubber or other insulating material put together alternately, a number of smaller metallic plates, one for each of the electric circuits between which connections are to be made, the smaller plates secured to one of the large insulating plates, and a peg-hole in and through each small plate extending also through all the large plates.

5140. "Telephonic and telegraphic signalling apparatus." A. C. BROWN and H. A. C. SAUNDERS. Dated November 24. 6d. Has for its object improvements in telephonic and telegraphic signalling apparatus. The improvements are applicable mainly where a series of stations are connected by a line wire, and where it is desired that any station may when the line is unoccupied, be able to place itself in communication with any other station on the line, excluding other stations, so that they can neither hear nor interrupt. At each station an instrument is provided with a graduated series of resistances which the operator can insert in the line circuit to vary its resistance. Each instrument is provided with an electro-magnet with armatures held back by springs differently adjusted, or other like contrivance for appreciating the resistance in the line circuit (the battery remaining constant). This appreciating contrivance controls the connections both of the resistances and of the receiver and transmitter, preventing their being placed in effective connection with the line circuit, except the resistance of the line circuit has been set to a pre-arranged quantity. Each instrument is provided with blocking parts, which render the variation of the resistance inoperative in the instrument in which it is produced. This combination works together in the following manner:—An operator wishing to call another station moves a handle to a corresponding mark, and thereby he first blocks and renders inoperative the appreciating contrivance of his own instrument, and then adjusts the resistance of the line circuit. The appreciating contrivances at all the other stations respond, preventing effected connection being established with the line at all stations but the one having an instrument adjusted to the particular resistance which has been brought about. The bell at this station being rung, the operator there moves his handle, thereby blocking his instrument also, and establishing the communication. On the handles being replaced the line is ready for other stations similarly to converse. When an induction coil is made use of in connection with telephonic apparatus, a secondary coil is divided into sections and made use of as resistance to be added to the line circuit to effect the desired adjustment. The coils of the telephone can be similarly employed.

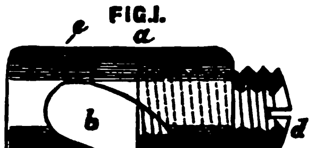
5159. "Galvanic batteries, &c." R. E. B. CROMPTON and D. G. FITZ-GERALD. Dated November 25. 4d. Relates to the construction of the electrodes of galvanic batteries, especially of the type known as secondary batteries or electro chemical accumulators. In these batteries it is desirable to increase as much as possible the surface of the electrodes, and

sometimes to give to them a structure which permits of large quantities of gas being occluded or retained at or near the surfaces. This is accomplished by giving to the electrodes a highly porous structure, and otherwise extending their surface in the following manner:—The electrode is made of a mixture of lead and some other substance capable of being extracted and removed therefrom by the action of water, acids, or other chemical re-agents, or by heat, or by electrolysis. When the mixture has been made into a shape suitable for the electrode the foreign substance is removed, wholly or partially, by some of the means herein before referred to, and the lead of the electrode is left with a porous structure, which greatly increases the surface exposed to the electrolyte, when it is made to form part of a secondary battery.

5198. "Secondary batteries for the production, &c., of electric currents." C. H. W. BIGGS and W. W. BEAUMONT. Dated November 28. 6d. In the usual form of secondary electric batteries, the products of electric decomposition appearing at the poles of the charging battery or dynamo or magneto-electric machine are collected and retained in the charged battery itself. Now according to this invention, the inventors prevent loss of these products, and regulate the recombination of these products in a better manner by collecting and retaining the same in two connected holders, and recombining them in the quantities required in order to produce electric currents.

5226. "Joining branch to main conducting wires for electrical purposes," &c. A. W. BREWTNALL. Dated November 29. 6d. Relates to improved means of coupling branch wires to main conducting wires or cables, as required in the installation of electric lamps for example, whereby the connection of the wires may be made, and the insulation of the coupling effected with great ease and rapidity. The coupling consists of a screw stud perforated with a longitudinal hole, through which the end of the branch wire to be connected is passed freely, and having a cross groove in its head at one side, intersecting the longitudinal hole, and forming a hook-shaped jaw fitting upon the main conducting wire or cable (bared of its insulating covering) which lies therein, and is tightly gripped between the jaw and a nut screwing upon the threaded stem of the coupling. The nut presses the main wire or cable forcibly into the jaw and against the branch wire at the intersection of the jaw with the longitudinal perforation, the act of screwing up the nut thus

FIG.1.



binding the branch wire tightly in the coupling and clamping the latter firmly upon the main wire or cable, thereby insuring a secure attachment and a good electrical connection between the two wires. The figure shows the improved form of coupling. *a* is a cylindrical stud (made of brass or other suitable metal), having a transverse groove cut in it at one side to form a hook-shaped jaw, *b*, to receive the main wire or cable (bared at this point of its insulating envelope), and provided with a binding screw, *d*, screwing into or upon the stud, and with a hole, *e*, intersecting with the groove of the jaw, *b*, so that the wires placed in the jaw and hole respectively shall be in contact at the point where they cross one another. This hole, *e*, passes transversely through the stud, *a*, and the screw, *d*, is a male screw, screwing into a corresponding female screw, tapped in the stud, *a*, and screws up against the main wire or cable lying in the jaw, the act of tightening up the screw forcing the cable into the jaw and into contact with the branch wire, binding the latter tightly in the coupling, thus affording a secure and ready means of attachment and a good electrical connection.

5229. "Utilisation of electricity for lighting, &c." W. R. LAKE. (A communication from abroad by J. S. Williams, of Paris). Dated November 30. 4d. The first part of the invention relates to the development of light and heat by means of electricity, and also to the devices or apparatus to be employed therein or therefor. In order to produce light the inventor causes the electric current to pass through pulverized or granulated particles of conducting material. The material preferred is carbon, but other materials, alloys, or compound substances may be employed. The said material is enclosed in a transparent tube or case, which may be formed of glass or other suitable material, the space or chamber in which the particles are placed being of such form and dimensions as will be best suited for the development of light with economy. By completing the circuit through a conductor composed of particles, granules, or sections, a high resistance is obtained, and heat and light are generated successfully and economically. *(Provisional only.)*

5234. "Fire alarms, &c." W. T. BRAHAM. Dated November 30. 6d. The first part of this invention consists of an apparatus that shall on the occurrence of a fire in its immediate vicinity do any or all of the following acts, that is to say, it may sound an alarum, or alarums, transmit electric currents, or telegraphic signals, to any place or places desired, or turn on a supply of water, through a series of perforated pipes, for the purpose of extinguishing the flames. In carrying out this part of the invention the inventor employs, for the purpose of liberating, or setting the apparatus in motion, a vessel of convenient size, and of a material which is an insulator to electricity, as a glass tube, in which is placed some mercury. Upon the mercury is placed a suitable float, which, when a fire occurs, will be carried upwards by the expanding mercury and come in contact with and liberate a trigger which releases the apparatus. The apparatus is actuated by means of a weight or coiled spring, and when the spring or weight is released, as before described, the revolving barrel, by means of a chain winding round it, draws back a lever and liberates a heavy key, which in falling turns on the water supply. The barrel of the apparatus is connected by cords or wires with a distinct apparatus consisting of a driving barrel, the axis of which carries a wheel, upon which is mounted a revolver charged with blank cartridges. This wheel carries as many studs as there are chambers in the revolver; these, as they rotate, raise a lever, which as soon as a stud has passed it is forcibly driven by a spring on to the revolver nipple, and so explodes a cartridge. A lever having its fulcrum on the framing of the apparatus is connected at one end by means of a wire, or cord, to a bell, the other end of the lever is actuated by successive teeth, or pins, upon a wheel gearing with the driving wheel of the apparatus, so that the bell rings continuously until the apparatus has run down.

5272. "Electric lamps." W. F. KING and A. B. BROWN. Dated December 2. 6d. Relates to electric lamps of the kind giving light by the arc between carbon points, and it comprises simple and efficient apparatus for moving one or both carbons in a manner to compensate satisfactorily for their gradual consumption, and to keep the light very steady; also automatic apparatus whereby the current supplying two or more lamps is maintained without any (but possibly a momentary) interruption in the event of any one of the lamps ceasing to act, and whereby an extinguished lamp takes its place in the circuit again whenever it has been either automatically or otherwise adjusted or restored to a working condition. In carrying out the invention according to one modification, in which the carbons are in a vertical line, the upper carbon is held by the bottom end of a rod which passes up through a stuffing box into a vertical cylinder of size and length corresponding to the size and length of the carbons employed. A piston working in the cylinder is fixed or connected to the upper end of the rod, and the cylinder is filled with oil or other suitable liquid. The weight of the piston and rod and parts attached to it tends to force the liquid from the bottom end of the cylinder through a small passage or pipe leading to the top of the cylinder, and the rate of flow through this passage or pipe is automatically adjusted to correspond to the rate of consumption of the carbons. For the purpose of the adjustment the passage or pipe has for outlet at its upper end a small port in a horizontal port face, on which there rests a small slide valve; and this valve is connected to the iron core of a solenoid placed horizontally, and to an adjustable spring, the spring tending to open the valve and the solenoid to close it. The electric current working the lamp is made to pass through the coil of the solenoid; and when in consequence of too great separation of the carbon points and increased resistance the current passing through the solenoid is weakened it allows the spring to draw back the iron core and open the valve; and when the carbon points are too near the consequently stronger current causes the solenoid to act on the iron core so as to close the valve more or less and thereby diminish the rate of descent of the upper carbon. When the spring is properly adjusted the action of the parts is to keep the distance between the carbon points practically uniform. The liquid passing the valve flows into the upper end of the cylinder; and when a carbon has been consumed the rod and piston are raised for receiving a fresh carbon, the liquid passing from the upper to the under side of the piston through a check valve in the piston or in a separate passage; or the piston may be constructed so as on being pushed up to positively open a valve or passage through it for the liquid.

5600. "Electric lighting apparatus for railway trains, &c." SYDNEY PITT. (A communication from abroad by Eli T. Starr, of the City and County of Philadelphia, America.) Dated December 21. 6d. Relates to an improved organisation of instrumentalities for producing the lights which are required on board of railway trains for illuminating the track at night in advance of the locomotive, and for exhibiting a warning signal in the rear of the train, or for other analogous purposes. The inventor makes use of apparatus for generating or producing electric currents by the conversion of mechanical energy derived from the motion of the train itself into electricity, store a portion of the electricity so produced for use at such times as the train is not in motion, and apply the same to the development of light from electric lamps placed at suitable points upon the train. The invention consists in certain new organisations and combinations of parts or devices.

1882.

931. "Dynamo-electric machines." A. M. CLARK. (A communication from abroad by Henry Brinsley Sheridan, of Cleveland, America.) Dated February 25. 6d. The object of this invention is to produce dynamo-electric machines so constructed that the current induced in the armature will be without wide breaks and nearly continuous, and also to increase the efficiency of the said machines. The invention consists in a dynamo-electric machine constructed with its field magnets made oblong in cross section, and arranged in two series in a circle around the armature shaft with the poles of the opposing series facing each other, and arranged at a sufficient distance apart to receive the armature between them, the poles of each series nearly overlapping each other laterally, forming a nearly continuous magnetic field; also in the armature constructed of a hollow iron ring nearly rectangular in cross section, and with its sides converging or inclined inwards from the periphery towards the inner side; also in the hollow ring armature made with corresponding openings in its periphery and inner sides, and projections of uniform thickness upon its inclined or converging sides, whereby the outer part of the armature is brought nearer to the magnetic field of force than the inner part; also in the hollow ring armature made with two series of projections of different shape alternating with each oth-- the projections of the one series being made V-shaped or with ‹ verging sides, and the projections of the other series being made slightly inclined or converging sides and V-shaped ends, whe

channels or grooves of uniform width are formed to receive the helix coils; also in the combination with the armature having lugs and the armature shaft of the hubs having flanges, whereby the said armature will be firmly connected with the said shaft; also in the combination with the armature and the armature shaft of the stationary magnet cores and the helices, the said cores being placed spirally around the armature shaft and at an inclination with the said shaft, and the said helices being wound with their coils parallel with the magnetic field of force, whereby the field of force will be elongated in the direction of the armature's movement, as will be hereinafter fully described. Fig. 1 is a sectional side elevation of one form of the machine taken through the line, *w*, *w*, fig. 2. Fig. 2 is a sectional end elevation of

FIG. 1

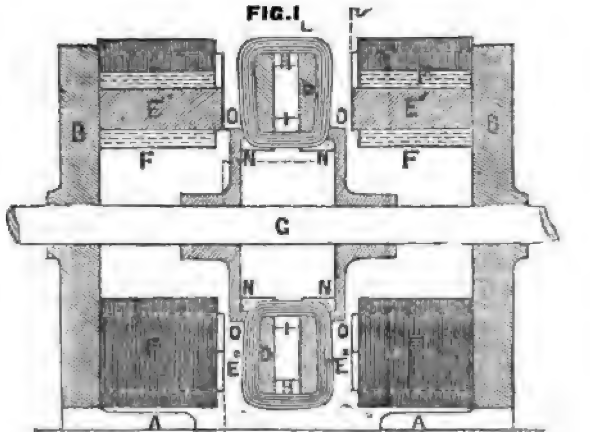


FIG. 2

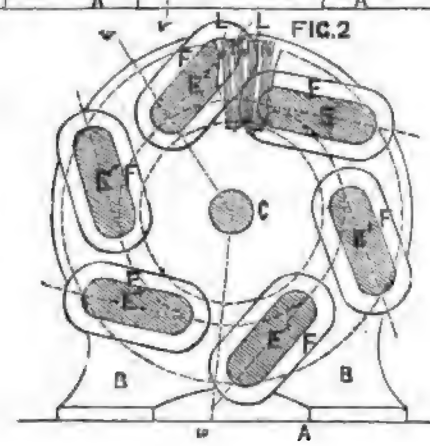

the same taken through the line, *v*, *v*, fig. 1. A is the bed plate of the machine; B B are two standards attached to the bed plate, A, and having bearings in which revolves the shaft, C, that carries the armature. The standards, B B, also form the seats and supports for the stationary magnet cores, E^2, around which are wound helices, F, of insulated copper wire. The magnet cores, E, stand with their axes in a spiral line of convenient direction and pitch around the axis of the shaft, C. With this arrangement the stationary magnet cores present an oblong field of force to the armature, the length of the field of force depending upon the pitch of the magnet cores, E, and their inclination from the axis of the shaft, C. The magnet cores, E, are arranged with the longest diameters of their fields of force in the direction in which the armature revolves, by which arrangement the projections of the armature will remain longer in the fields of force, and the generated currents will thus be considerably increased. One of the magnet cores, E, with the surrounding helix can be one pole of an electro-magnet, or two or more of the said cores, E, can be connected on their faces by a plate, and thus form only one pole of an electro-magnet. The series of magnets are arranged in circles around the shaft, C, one series being attached to each frame, B. The magnet cores, E^2, are made oblong in cross section, and are arranged in inclined positions with reference to each other, so that they nearly overlap each other laterally, the side of one magnet being tangential to the rounded edge of the adjoining magnet, and so on throughout the series. With this arrangement the face of the pole of each magnet is arranged diagonally across the path of the armature ring in the plane of its rotation. This construction brings the magnets into such positions that each section coil of the armature will pass upon the pole of each magnet at the instant it leaves the pole of the preceding magnet, so that the current induced in the armature will be without wide breaks and will be nearly continuous. With this construction the armature can be revolved in either direction.

THE ANGLO-AMERICAN TELEGRAPH COMPANY.—At a meeting of the board of directors, it was resolved, after placing £37,500 to the renewal fund, to declare an interim dividend for the quarter ending June 30th, 1882, of 15s. per cent. on the ordinary stock, and 30s. per cent. on the preferred stock, both free of income-tax, payable on August 1st, to the stock-holders registered on the books of the company on July 7th, 1882.

THE WESTERN UNION TELEGRAPH COMPANY.—This company has declared a quarterly dividend at the rate of 6 per cent. per annum upon its stock, payable on July 15th. The surplus proposed to be carried forward after payment of this dividend is unusually large.

EASTERN EXTENSION TELEGRAPH COMPANY.—A dividend of 2s. 6d. per share for quarter ended 31st March, will be payable on July 15th.

EASTERN TELEGRAPH COMPANY.—Notice is given that subject to the final audit, the accounts show, after placing the sum of £75,000 to reserve, a balance sufficient to pay the fixed dividend of 3s. per share, equal to 6 per cent. per annum on the preference shares, and a final dividend of 2s. 6d. per share, with a bonus of 1s. per share on the ordinary shares, both free of income-tax; making, with previous payments on account, a dividend for the year ending March 31st, 1882, of 5½ per cent. on the ordinary shares. A balance of about £1,000 is carried forward.

EASTERN AND SOUTH AFRICAN.—The interest on the 5 per cent. mortgage debentures now due will be paid by Messrs. Barclay, Bevan & Co.

CUBA SUBMARINE TELEGRAPH COMPANY.—The directors of this company state that, after providing for the dividend on the preference shares and placing £3,950 to the reserve fund, they have resolved to recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income-tax, leaving £2,146 to be carried forward to the current half-year's account.

APPLICATION has been made to the Stock-Exchange Committee to appoint a special settling day in and to grant a quotation to the following securities:—Metropolitan Brush Electric Light and Power Company (Limited), and Railway Electric Appliances Company, shares.

QUOTATIONS have been granted to the Great Western Electric Light and Power Company, and to the Indian and Oriental Electric Storage and Works Company.

QUOTATION of the Brush Electric Light and Power Company of Scotland (Limited), has been deferred.

THE TELEGRAPHIC JOURNAL AND

Electrical Review.

VOL. XI.—No. 242.

THE ELECTRIC LIGHT IN THE CITY OF LONDON.

SOME interesting statistics are to be found in the recently-issued Report to the Streets Committee, by Mr. William Haywood, the engineer and surveyor to the Commission of Sewers. It deals of course exclusively with the experiments of the past year, commencing from the 1st of April, 1881, and ending on the 31st March of the present year. It is well known that the Electric Light and Power Generator Company (Maxim-Weston) did not commence on the strict terms of their contract until the 27th of April of this year, therefore the matter contained in Mr. Haywood's report is chiefly confined to the systems of Messrs. Siemens Brothers and the Anglo-American Brush Company. One of the most interesting items in connection with the use of the electric light in the City is that relating to its defects and failures. In the Brush district were 33 lamps, each assumed to be alight for 4,300 hours during the twelve months, this being equal to a total of 141,900 hours' lighting of a single lamp. The total number of the failures which happened to this system from all causes amounted to 660, counting each failure each night separately, and the aggregate duration of such defects equalled 3,142 hours' burning of a single lamp, or about 2·21 per cent. of the entire lighting of the district for the year. The causes assigned for these failures are very numerous, amongst them being many which will probably not be likely to occur again, such as: lace of driving-band broke; switched out maliciously; changing the working power of circuit from one motor to another; defects in carbons; carbon-rod sticking; top carbon falling from socket; neglect in trimming; bad insulation of cables; carelessness of men employed on circuit; defective mechanism of lamp, &c., &c.

The total number of failures from much the same reasons as above, chronicled for the system of Messrs. Siemens—having 34 lamps in action, and equalling a total of 146,200 hours' lighting from a single lamp—were 320, or approximately only half of those credited to the Brush, their aggregate duration, however, being only 832 hours of a single lamp, or about 0·57 per cent. of the entire lighting of the district for twelve months.

Speaking roughly, there occurred in the Brush system a defect of long or short duration in something less than two lamps nightly, and in that of Siemens Brothers a similar defect in something like one per night. In both systems failures happened through bad insulation, the first cable of the one not being sufficiently good to begin with, and that of the other being damaged by a barge, part of the cable being beneath London Bridge. Although these partial failures were numerous, the result at the end of the year was really better than might have been expected, even by those who are the most conversant with the management of the apparatus connected with the electric light. Even gas, however, has a bad record against it in this respect, for out of a total of 3,225 lamps, the number of defective lights observed in 1881 amounted to no fewer than 2,509, and this only includes burners, in which the defect is very noticeable. This number, which according to the Report was much in excess of what is usual, is attributed to the long continued and severe frosts.

Whenever any accident occurred to the electric lamps but little inconvenience was felt by the public, as arrangements were made with the gas company for burning gas where these partial interruptions happened. The expense of this was borne by the electric lighting contractors, and in the case of Brush the amount came to £129 14s. 7d., and for Siemens £122 9s. 7d.

The electric lamps were alight in the day-time during the fogs of December 9th last, and also on the respective dates of the 18th, 25th, and 29th of January, together with the 2nd, 3rd, 6th, and 7th of February. The cost of the electric light during these fogs was as follows:—Brush, £25; Siemens, £21 3s. 9d.

It is only necessary to mention that the Commission of Sewers arranged with the Brush Corporation for a further period of twelve months lighting, at a cost of £800, being £140 in excess of the charge for the preliminary year's work. Messrs. Siemens Brothers requiring for a continuance of their contract £1,330 in excess of their original price; their offer was declined, and the district for the present returns to gas.

A second report from the Streets Committee relates to proceedings relative to the applications for an extension of the electric lighting experiments. According to the abstracts of tenders prepared by Mr. Haywood, and received for lighting the four districts set apart for this purpose, it appears that there are seven contractors desirous of obtaining the work. Their names are as follows:—G. D. Cardew, employing G. H. Long's patent electric lamps and machines; the Electric Light Engineering Company, with the arc lamp of Mr. A. A. Common, but machines not described; the Electric Light and Power Generator Company, with the Weston machines and arc lamps, as now in use along Queen Victoria Street; Mr. A. L. Fyfe, lamps and machines not described; James Fyfe, with two tenders for the Pilsen arc and the Joel semi-incandescent lamps respectively; the Hammond Electric Light and Power Supply Company, using Brush machines and lamps; and last, the Laing Electric Light and Power Company, proposing to employ the Laing machines and lamps. The second and third mentioned contractors stipulate that they should have permission to light private premises, the Electric Light and Power Generator Company, however, tendering for No. 1 district only.

We gave in our last issue an extract from a letter written by Mr. Alexander Peebles, relating to the prices quoted for the various districts by the competing companies. We may add that for district No. 1 the highest and lowest tenders are those of the Electric Light and Power Generator and the Hammond Electric Light companies, with £5,750 and £2,190 respectively. For district No. 2, G. D. Cardew and the Laing Company, with £4,270 and £2,350, are respectively highest and lowest. In tendering for No. 3 district James Fyfe, with the Joel system, £3,800 is highest,

and the Hammond and Laing Companies, with the same estimate of £2,470, lowest. For No. 4 district, James Fyfe, with the same system, is again highest—£4,350, and the Laing Company, with £2,920, lowest. These tenders are all for the total cost of a twelvemonth's trial. It is only fair to add, however, in the case of Mr. Fyfe, with the Joel and Pilsen systems, that he would, if permitted to light private premises, make the charge for street lighting the same as the gas saved, plus 20 per cent.

The percentage of variation in the estimates sent in will be found in the letter of Mr. Peebles before referred to, and this variation bears out, to a certain extent, the following extract from the *Globe*:—

It ought, one would think, to be possible, after all the investigations which have taken place, to say once for all whether electric lighting or gas lighting is the cheaper, but if we may judge from a long letter sent to us by Mr. H. Saxon Snell, the controversy is still very much *sub judice*. The tenders for a given job, obtained by Mr. Snell from three several electric light companies, differed very much as contractors' tenders are apt to differ, and all were far beyond what, according to Mr. Snell, the cost of gas would be.

The estimated cost for lighting the four districts, taken in rotation, is £551, £363, £341, and £612.

The Streets Committee conclude their report in the following manner:—

Looking at the experiments which the Commission have already carried out, and the great cost of extending the same, as shown by the offers now submitted, we are not prepared to recommend your Honourable Court to proceed further in the matter at present, the more so as by the bill now before Parliament, and draft amendments suggested by the Board of Trade, it is proposed to give power to the local authorities to supply electricity, not only for public but for private purposes, or to acquire compulsorily the undertakings of other parties after fifteen years from the passing of the Act under which they may be empowered, and until Parliament has decided the principle upon which electric lighting generally shall be permitted, we consider it undesirable to incur further expense beyond that to which the Commission are already committed by the experiments now in operation.

THE EDISON DYNAMO-ELECTRIC MACHINE.

[We extract from the excellent journal of the Franklin Institute of America the following description of the Edison steam dynamo, a paper on which was read by T. A. Edison, Ph.D., and Charles T. Porter, at the Philadelphia meeting of the American Society of Mechanical Engineers, April, 1882. Containing, as it does, much that is new regarding what is known here of the performance of these machines, it will be welcome to those of our numerous readers interested in electric lighting. The original paper contains a perspective illustration of the combined engine and machine, which it is not necessary to reproduce, as the Edison machine has already been given by ourselves (see "ELECTRICAL REVIEW," November 5th) and other journals in this country. There are also several sketches of mechanical details, and five indicator diagrams taken from the engine, which need only be referred to.]

THE central Edison station of the first district in New York City will, when fully equipped, be supplied with twelve dynamos, each of which is nominally rated as a 1,200 light machine, at 16 candle-power incandescence, but is capable of supplying 1,400 lights of this power continuously, and with high economy, without heating the armature or burning or injuring the commutator or brushes. This increased capacity is due to improvements in the lamp itself.

The armature of each dynamo is driven by a Porter-Allen engine, of $11\frac{3}{16}''$ diameter of cylinder, by 16" stroke, directly connected, and making 350 revolutions per minute, giving a piston travel of 933 ft. per minute.

The steam is supplied by eight Babcock and Wilcox boilers, of 2,000 aggregate horse-power, and which will work under a pressure of about 120 pounds. These occupy the basement of the building. Over them, the first and second floors being removed, an iron superstructure is erected entirely separated from the walls of the building, and on this the combined dynamos and engines are placed.

One-half of this equipment is now nearly ready for service, and the remainder is expected to be completed during the coming season.

The armature of the dynamo is of the form commonly known as the Siemens armature, but in its construction and "connecting up" it differs radically from all others.

The foundation of the armature, or the iron core which is built upon the shaft, is made up of sheet-iron discs, separated from each other by sheets of tissue paper, and bolted together. This has all the advantages of a solid iron core in strengthening the magnetic field, while it completely prevents the great loss of power by local currents, which would circulate in the iron if it were solid. In the place of insulated wires, the cylindrical face of the armature is made up of heavy copper bars, trapezoidal in section, each bar being insulated, and also separated from its neighbours and from the iron core underneath by an air space.

The connection between the bars on opposite sides of the armature, to form the electrical circuit, is made by copper discs of the same diameter as the core. At each end of the core are one-half as many of these copper discs as there are bars, each disc being insulated from its neighbours, and the whole being bolted together in such a manner as to form, with the discs of sheet-iron constituting the core, one solid mass. Each disc is formed with projecting lugs on its opposite sides, to which the two bars are connected.

The connections between the opposite surfaces of an armature are of no benefit in generating an electric current, but are a necessary evil, introducing useless resistance into the circuit. By using for this connection copper discs in the manner described, a great weight of copper is disposed in a limited space, and so this useless resistance, and consequent loss of energy, is reduced to a minimum.

This method, moreover, reduces the work to a simple machine construction, in which all the parts are duplicates, and the operations can be much cheapened and facilitated by the use of special tools.

The spaces between the armature bars admit of a free circulation of air, thereby preventing the accumulation of heat, and increasing to an enormous degree the capacity of the machine. The armature is at intervals wound with piano wire over the bars to resist the centrifugal force developed by their revolution.

The commutator and brushes of an electrical machine are the parts subject to the greatest depreciation. In this machine all parts of the end of the armature are so constructed as to be easy of access, and they can be quickly and cheaply repaired, or removed and replaced by new parts, when necessary. Any accident would require but a short stoppage for repairs.

Provision is made for keeping a continuous and rapid circulation of air over the entire face of the armature.

This armature is 27·8" in diameter by 61" long. The commutator adds 18" to this length, and is itself $12\frac{3}{4}''$ in diameter. The armature shaft is of steel, $7\frac{1}{4}''$ in diameter, having a total length of 10′3″. The journals are $6\frac{1}{2}''$ in diameter by 15" long, and run in Babbit metal bearings in pillow blocks of the box form, giving the greatest stiffness with minimum of weight.

Provision is made for continuous water circulation underneath the boxes, and for continuous lubrication, with traps to prevent the creeping of the oil along the shaft and reaching the commutator, and drains to receive it as it runs through the bearings and convey it to a drip-pan.

The magnet is made up of two immense cast-iron "pole-pieces," between the semi-cylindrical faces of which the armature revolves, twelve cylindrical soft iron cores attached to these pole-pieces, and made magnetic by an electrical current circulated in the wire wound around them, and four soft iron keepers connecting the back ends of the cores. Eight of the cores are attached to the upper pole-piece, and four to the lower one.

The width of these "poles" is 49", and their height $61\frac{1}{4}''$. The length of the twelve soft iron cores is 57", the diameter

of the eight upper ones is 8″, and of the four lower ones 9″. The four soft iron keepers are each 11″ wide, 9″ in thickness, and the total length of the magnet is 94″.

The magnet is insulated by cast zinc bases 3″ in thickness. The weight of the dynamo is as follows:—

Armature and shaft - -	9,800 lbs.
Two pillow blocks - - -	1,340 „
Magnet, complete - - -	33,000 „
Zinc bases - - - -	680 „
Total - - -	44,820 lbs.

The copper is distributed as follows:

In the armature bars - -	590 lbs.
„ „ discs - -	1,350 „
„ magnet wire - -	1,500 „
Total - - -	3,440 lbs.

Mr. Edison was early impressed with the conviction that to give steady and reliable motion to these armatures it would be necessary to connect an engine to each one of them directly. This combination has been termed by him the "steam dynamo."

In adapting the Porter-Allen engine to this service, a special construction in some respects was found to be called for. These special features will be briefly described.

It seemed important to avoid a rigid connection between the engine and the armature shafts, which would require the entire series of bearings to be maintained absolutely in line. In place of this, therefore, a self-adjusting coupling has been introduced, which permits of considerable errors of alignment without any abnormal friction being produced in the bearings.

The point of difficulty was the backlash, the engine having no fly-wheel, except the heavy armature itself, which was to be driven through the coupling. Provision was made for taking this up by steel keys of a somewhat peculiar form, between which the tongues of the coupling move freely, while they themselves are immovable. These keys are held between set screws threaded in wrought iron rings covering the flanges on the ends of the shaft. All the faces liable to move upon each other are oiled from a central reservoir. This coupling is a very compact affair, without a projection anywhere above its surface, and gives every promise of completely answering its purpose.

The engine is made with a forked bed and two shaft bearings and a double crank, and so is completely self-contained.

The shaft having no support beyond these bearings on either side, unusual stiffness was required in the crank-pin to prevent deflection under the great strains to which it is subjected.

A novel form of pin was proposed by Mr. Richards, which is found to possess all the rigidity required. It is provided with flanges which are let into each crank, and held each by four screws, while the shanks of the pin are also forced firmly into the cranks.

Special appliances enabled the work of putting the cranks together in this manner to be done with extreme and uniform accuracy.

The engine is so arranged as to have the valve gear on the side furthest from the dynamo. The engineer has not to go between the engine and dynamo, when running, for any purpose.

The connecting-rod is of steel, and the crank-pin boxes are formed directly in the end of it.

This end is finished from a solid forging, and chambered out for Babbit metal. The bolts are then fitted, after which it is parted and holes are drilled for holding the Babbit securely.

In the connecting-rods for single crank engines of this type permanent length of rod is secured by forming the crank pin end solid, and taking up the wear by a wedge closing up the inside box. In these double crank engines this construction is impracticable, but the same object is attained by forming the crosshead end in a manner by which the strap is made permanent and the inside box is closed up by a key bearing against a steel plate.

The weight of the reciprocating parts of this engine is as follows:—

Piston, with rod - - - - - -	83 lbs.
Crosshead - - - - - - -	42 „
Connecting-rod - - - - - -	109 „
Total - - - - - -	234 lbs.

The initial acceleration of this mass or the force required, on the dead centres, to give it the motion necessary to relieve the crank from strain, is as follows:—

$$350^2 \times \cdot66 \times \cdot000341 = 27\cdot57,$$

or 27·57 times the weight of the mass, which gives

$$234 \times 27\cdot57 = 6451 \text{ lbs.}$$

The formula is $r^2\, l\, c$, when

r^2 = the revolutions per minute;
l = the length of the crank in decimals of a foot; and
c = the co-efficient of centrifugal force.

The connecting rod is 48″, or 6 cranks, in length. This affects the initial acceleration, making this to be on the dead centre farthest from the crank 7,526 lbs., and on the dead centre nearest to the crank 5,376 lbs., a difference of 40 per cent.

The area of the cylinder is 98·2 square inches.

The area of the piston rod, $1\frac{3}{4}$ in. diameter, is 2·4 square inches, leaving area of cylinder at crank end 95·8 square inches.

The initial accelerating forces are therefore as follows, viz.: at the end of the cylinder farthest from the crank 77 lbs., and at the end of the cylinder nearest to the crank 56 lbs., on the square inch of piston area.

The counterweight was after some trials fixed at 135 lbs. This leaves 99 lbs. of the reciprocating parts running unbalanced. It is found that this is not sufficient to disturb the stability of the engine, while on the other hand the counterweight is not so great as to exert an objectionable strain in the vertical direction.

The total weight of the engine is 6,445 lbs.

The engine and dynamo are mounted on a cast-iron base plate, made for convenience in two parts, and bolted together.

The dimensions of this base plate are as follows: length 14 ft., width 8 ft. 9 in.; and its weight is 10,300 lbs. The entire weight is therefore as follows:—

Base plate - - - - - -	10,300 lbs.
Dynamo - - - - - -	44,800 „
Engine - - - - - - -	6,450 „
Total - - - - - -	61,550 „

The last and most careful test of one of these dynamos gives the following results, as shown by the indicator diagrams; scale 80 lbs. to the inch.*

The lamps used in all the trials were of the older construction, of which $8\frac{1}{2}$ lamps, at 16 candle-power incandescence, require one horse-power of electrical energy.

Since these were placed for experimental uses, improvements in the lamp have increased their economy, so that one horse-power is sufficient to maintain fully 10 of the present lamps at 16 candle-power incandescence.

	Horse-power.
Diagram No. 1 shows the friction of engine and dynamo at 350 revolutions per minute, requiring	13·63
Diagram No. 2 shows the resistance with the magnet circuit on = - - - - -	19·17
Field 5·78 ohms, 103 volts.	
The increased resistance due to the magnets was -	5·54
Of this, the calculated energy developed in the magnets was $\dfrac{103^2 \times 44\cdot3}{5\cdot87 \times 33{,}000}$ = - - - -	2·46
Leaving energy to be accounted for by local currents in iron core of armature, and in armature bars - - - - - - - - -	3·08

* As many persons might doubt about these diagrams having been really taken from any engine and by any indicator at this speed, we have examined the originals taken by a Tabor indicator, and can vouch for their accuracy.—ED. J. F. I.

Diagram No. 3 shows the work done in maintaining 300 lamps.

These, in the ratio of $8\frac{1}{2}$ to 10, were equal to 353 lamps of the present construction. The pressure was maintained also at 102 volts, representing 25 candle-power, in place of 98 volts, representing 16 candle-power incandescence, which requires the number of lamps to be increased in the ratio of 102^2 to 98^2, or to 382 lamps.

The pressure at the armature was 104 volts, showing a loss in the conductor of 2 volts, which would increase the number of lamps as 104 : 102.*

The total correction is therefore as follows :—

$$300 \times \frac{10}{8{\cdot}5} \times \frac{102^2}{98^2} \times \frac{104}{102} = 389 \text{ lamps.}$$

The power exerted was - - - - 60·6 horse-power.
Which gives to the indicated horse-power

$$389 + 60{\cdot}6 = 6{\cdot}42 \text{ lamps.}$$

The magnet circuit had now a resistance of 5·28 ohms with 104 volts pressure, representing

$$\frac{104^2 \times 44{\cdot}3}{5{\cdot}28 \times 33{,}000} = 2{\cdot}75 \text{ horse-power.}$$

Substituting this in place of 2·46 horse-power in the first trial, we have 19·46 horse-power, which, deducted from 60·6 horse-power, leaves net 41·14 horse-power.

This gives 389 ÷ 41·14 = 9·45 lamps per horse-power.

Diagram No. 4 shows the work done in maintaining 700 lamps.

The pressure at the lamps was maintained, as in the preceding trial, at 102 volts, which required at the armature a pressure of 105 volts.

The total correction in this case is therefore

$$700 \times \frac{10}{8{\cdot}5} \times \frac{102^2}{98^2} \times \frac{105}{102} = 919 \text{ lamps.}$$

The power exerted was - - 115·83 horse-power, giving to the indicated horse-power,

$$919 + 115{\cdot}83 = 7{\cdot}93 \text{ lamps.}$$

The resistance of the magnet circuit was now 4·78 ohms, with 105 volts pressure, representing

$$\frac{105^2 \times 44{\cdot}3}{4{\cdot}78 \times 33{,}000} = 3{\cdot}1 \text{ horse-power.}$$

Substituting this in place of 2·46 horse-power in the first trial, we have 19·81, which, deducted from 115·83 horse-power, leaves net 96·02 horse-power.

This gives 919 + 96·02 = 9·57 lamps per horse-power.

Diagram No. 5 shows the work done in maintaining 1,050 lamps.

The pressure at the lamps was maintained in this trial at only 99 volts, but this required at the armature a pressure of 108 volts, showing a loss of 9 volts in conduction.

The total correction in this case is thus

$$1050 \times \frac{10}{8{\cdot}5} \times \frac{99^2}{98^2} \times \frac{108}{99} = 1375 \text{ lamps.}$$

The power was - - - - - 168·4 horse-power, giving to the indicated horse-power

$$1375 \times 168{\cdot}4 = 8{\cdot}16 \text{ lamps.}$$

The resistance of the magnet circuit was now 8·28 ohms, with 108 volts pressure, representing

$$\frac{108^2 \times 44{\cdot}3}{8{\cdot}28 \times 33{,}000} = 4{\cdot}77 \text{ horse-power.}$$

Substituting this in place of 2·45 horse-power in the first trial, we have 21·48 horse-power, which, deducted from 168·4 horse-power, leaves net 146·92 horse-power.

This gives 1375 ÷ 146·92 = 9·36 lamps per horse-power.

* The conductors were insufficient, occasioning a loss, that increased with the increase in the number of lamps

It will be seen that the losses of efficiency due to undiscovered resistances are only

In the first case, 10 — 9·45 = ·55 horse-power per lamp.
In the second case, 10 — 9·57 = ·43 „ „
In the third place, 10 — 9·36 = ·64 „ „
Averaging 5·4 per cent.

The friction in the journals of the armature, when driven in this manner, does not increase with the resistance, and, on account of the action of the reciprocating parts of the engine, that in its bearings is also nearly a constant quantity, whatever the load may be.

The above figures show this very clearly, the subtraction of the friction diagram in each case exhibiting substantially the same net power per lamp.

KETTELL'S INDIVIDUAL TELEPHONE CALL AND SIGNAL.

THE progress which telephonic communication has made in England is but small compared with that made in America. The network of wires which has been spun all over the business portion of the Metropolis, and to some extent outside the City limits, would seem to contradict this statement; but it is only necessary to mention the fact that Worcester, a city in Massachusetts, of 63,000 inhabitants only, has more subscribers in telephonic communication than have all the exchanges in London, when it will be seen at once that what we say is correct. In countries where the use of the telephone is so extensive it is but natural that every effort should be made, not only to render the communication as effective but also as cheap as possible, hence it is that we find here so many telephonic exchange patents taken out by inventors in America, for cheapness of communication, to a very great extent, depends upon the exchange system employed.

Up to the present the arrangements of the exchanges in this country have been of the simplest character : every subscriber has a wire in direct communication with an exchange office, at which place he can be switched through to any subscriber he may require ; if it should happen that there are, say, six subscribers who are at a short distance apart on a direct line from the central office, still, with the present system, each of these subscribers must have a separate wire. Now it is evident that any device by which these six subscribers could be simply looped in on a single wire common to all, must lessen the outlay necessary to establish the communication, and must enable the latter to be supplied at a less rental than that demanded at present. It is of course necessary that the means by which the object in view is carried out be of a much less cost than that which would be required for the erection of a number of wires, for the lessening of the rental to a subscriber must be sufficient to compensate him for one small disadvantage inherent in a system in which a number of instruments are placed on one circuit, namely, that one subscriber has to wait until another subscriber has terminated his use of the circuit on which the two are looped, and has left the line clear. As a rule, however, the period of waiting does not exceed three minutes, a length of time which it is hardly worth while taking into consideration.

The proof of the pudding is the eating, and the system which we are about to describe has, by practical use over a period of a year and a half, proved that such an arrangement as that of looping several subscribers (as many as 10 have been so looped) on one wire, can be adopted with perfect success.

The solution of the problem has been more than once attempted, but, we believe, with but indifferent success. The system of Mr. Kettell is, in our opinion, the best which has yet been brought into practical use, and promises to be extensively employed.

The devices by which the apparatus is worked are of great mechanical ingenuity, and are very suggestive of applications to other purposes, and even for this reason the system is worthy of being described.

In order to explain the action of the instruments, it will

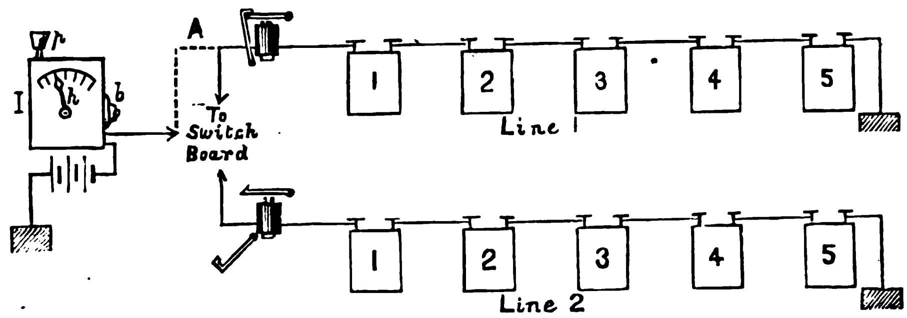

FIG. 1.

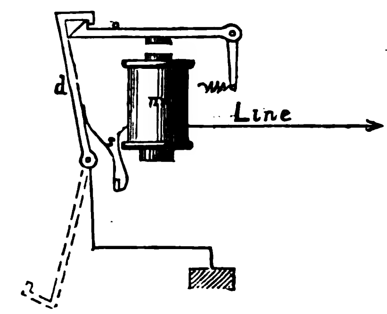

FIG. 2.

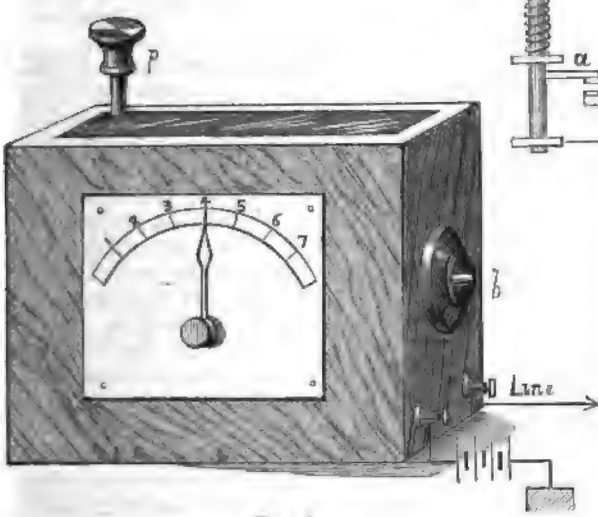

FIG. 3.

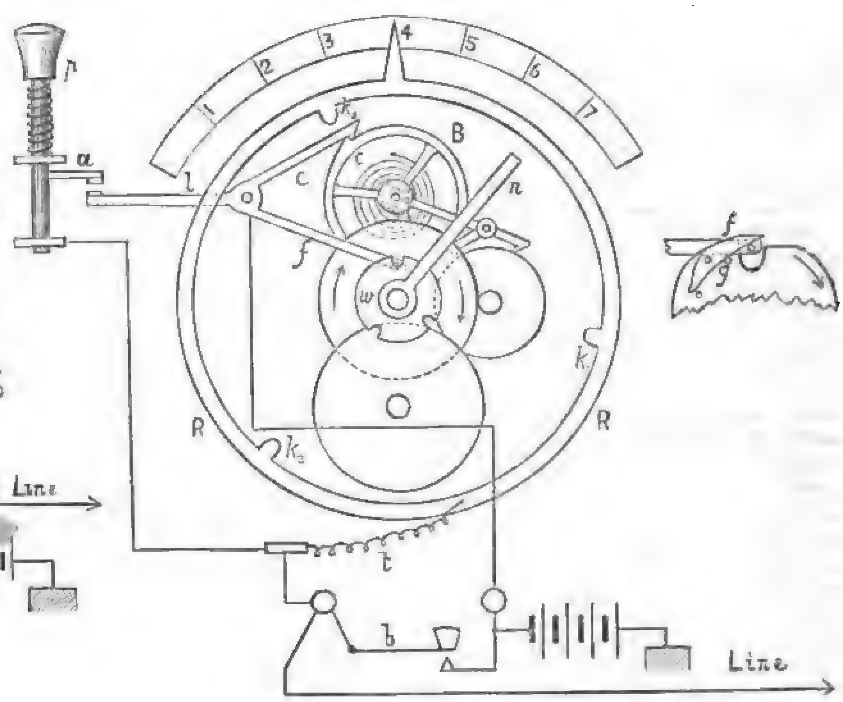

FIG. 4.

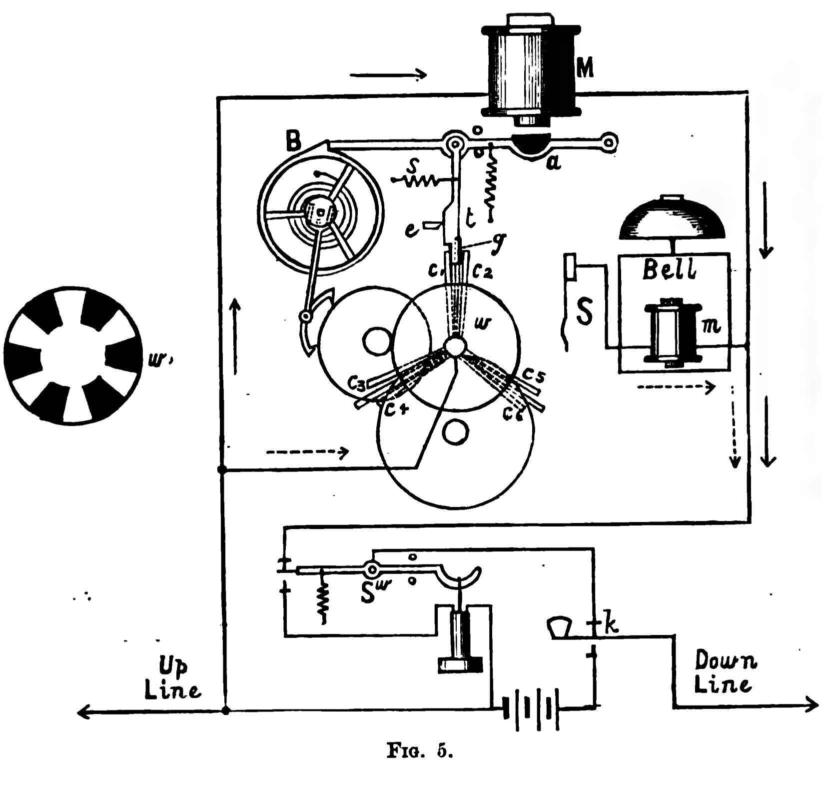

FIG. 5.

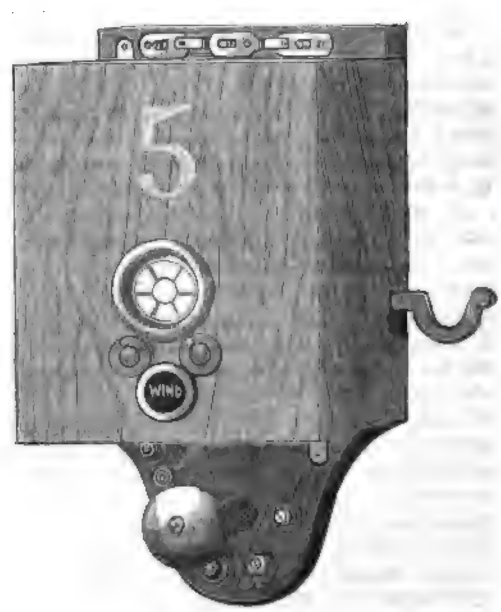

FIG. 6.

be advisable to consider the general arrangement of the system :—

Fig. 1 shows two lines running into a central exchange at A, each line having 5 subscribers looped into it; there may of course be any number of lines with a number of subscribers on each, but two will be sufficient for the purpose of the description.

Suppose now that subscriber 3, on line 2, wishes to communicate with subscriber 5, on line 1, then the following operations take place :—Subscriber 3 presses a push-button attached to his instrument, and thereby sends a current through all the instruments on the circuit, and also through a drop indicator at the central station, thus calling the attention of the latter. The indicator is of the usual form, but is arranged as shown by fig. 2, that is to say, the circuit from the electro-magnet, instead of passing direct to earth, goes to the latter through the medium of the contact spring, *s*, and the drop, *d*, so that when the latter has fallen to the position shown by the dotted line, the circuit becomes disconnected, and no more currents can be sent by pressing the press-button. The current which passes through the instruments of the various subscribers sets free some mechanism, which causes a small indicator on each instrument (seen just below the 5 in fig. 6) to turn and indicate that the line is occupied.

As soon as the central exchange station receives the call he switches his telephone in circuit with the line and communicates with the subscriber, who announces his number and also states with whom he wishes to communicate. As we have before said, let it be subscriber 5, on line 1. The exchange station now switches the apparatus, I (fig. 1), shown in outward form by fig. 3, on to line 1 (this connection is represented by the dotted lines in fig. 1); he then sets the hand, *h*, to indication 5, and depresses the push, *p*. The result of this is to ring the alarum of subscriber 5, and to turn the indicators of the instruments of *all* the subscribers to the position which indicates that the line is occupied; *but the alarums of the subscribers other than number* 5 *do not ring*. As soon as the exchange station observes that the mechanism of his apparatus (fig. 3) has ceased to run, he disconnects the latter and switches line 1 in communication with line 2; the subscribers thus put into connection communicate with each other. At the end of three minutes (which is the time allowed for a subscriber to converse) the exchange disconnects the two lines, and having again connected the instrument, I (fig. 1), to line 1, he depresses the button, *b*, once; this sets the indicators of all the subscribers to the position indicating that the line is clear; line 1 is then connected again to its drop indicator, and the instrument, I, is connected to line 2, the button, *b*, depressed once, the instrument, I, disconnected, and line 2 connected again to its drop indicator.

It will be evident that the peculiarity of the apparatus consists: 1st, in the arrangement by which the currents (*two* currents, as will be seen) sent by the depression of the stud, *p*, move the indicators of all the instruments to the position indicating that the line is occupied; 2nd, in the arrangement by which the alarum of only one subscriber is sounded; 3rd, in the arrangement by which the depression of the push, *b*, sets all the indicators to "line clear."

Fig. 4 shows the internal arrangements of the apparatus (fig. 3) at the exchange station. Fig. 5 shows the internal arrangements of the instruments at the subscribers' offices; an outside view of one of these instruments is shown by fig. 6. It must be understood that figs. 4 and 5 only show the general arrangements of the apparatus, the actual forms of the latter differ slightly in detail from the figures, though the general principles are identical.

Referring to fig. 4, let us suppose the stud, *p*, to be depressed and then immediately allowed to rise again. When the depression takes place, the projecting piece, *a*, comes in contact with the lever, *l*, and as the zinc pole of the battery is connected to *l*, and the line to the push, *p*, a current flows out to line, but ceases immediately the pressure is taken off *p*. The movement of the push has, however, depressed the lever, *l*, and caused the hook at the end of the prong, *e*, to disengage from the projection, *c*, on the balance-wheel, B. This balance-wheel is in gearing with a train of wheels driven by a strong spring—the whole mechanism of an American lever clock, in fact. The balance being released, the clockwork mechanism starts off in action. Now the movement of lever, *l*, also lifts a pin at the end of the prong, *f*, out of a notch in wheel, *w*, but as the movement of this wheel is comparatively slow, the pin would drop again into the notch and stop the train of wheels unless previous to *p* being allowed to rise, the wheel, *w*, has moved round through a few degrees; practically, however, the depression of *p* being only momentary, the wheel, *w*, will not have turned sufficiently to make the pin drop on to the circumference of *w*, instead of into the notch; so to avoid this difficulty the device shown to the right of the figure is adopted. On the face of the wheel, *w*, and near the circumference, there is set at each notch a small pawl, *g*, which falls to the position shown, by its own weight; when the prong, *f*, rises, the pin lifts up the pawl and, on clearing it, the latter drops back to its original position, thus closing, as it were, the notch and preventing the pin of the lever dropping back again. Supposing now the wheel, *w*, continues to rotate with the pin of the lever resting on its circumference, then this pin will be able to drop into the next notch, since it will enter towards the latter underneath the pawl. When the pin drops back into the notch, the prong, *e*, is ready to engage in the projection, *c*, of the balance wheel, B, which it does when the balance has swung nearly to the limit of its angular movement, so that when disengaged, the balance is ready to start off in full action immediately.

We see then that the momentary depression of *p* will start the clockwork; and as there are three notches in *w*, the movement will go on until *w* has turned through a third of a complete revolution; or as *w* turns once in a minute, the clockwork will run for one third of a minute before it stops.

Fixed on the axis of *w* is a light hand, *n*; this hand in a complete revolution makes contact with metallic projections, k_1, k_2, and k_3, successively; the projections are fixed on a metal ring, which can be turned through any desired angle by means of the pointer, *h* (fig. 3). It is evident therefore that the period which will elapse before the hand, *n*, makes contact with any one of the projections will depend upon the position of the pointer, *h*; if the pointer is set at division 1, for example, then on the clockwork being started contact will be made by the hand, *n*, almost immediately; but if the pointer be set at division 7, then a longer period will elapse before the contact occurs. The hand, *n*, being in connection, through the wheelwork, with the lever, *l*, and the ring, R, being in contact, through the flexible connection, *t*, with the push, *p*, it is evident that the result of the contact will be to send a current out to line. The depression of the push, *p*, in fact, sends a momentary current out to line, which current will be followed after a certain interval, which is adjustable, by a second momentary current. The possible angular movement which can be given to the ring, R, is less than one-third of a complete circle, whilst the hand, *n*, is so fixed on the arbour of *w* that when the pointer, *p*, stands at division 1 (the left hand limit of its movement) this hand is a little behind one of the projections on the ring, R. It follows from this that no matter what be the position of the pointer, *h*, the hand, *n*, after touching a projection, will always advance beyond it before stopping.

Referring now to fig. 5 let us suppose that the first current has been received from the central station, then this current comes from, say, the Up line, passes through the electro-magnet, M, and from thence through the switch lever, S^w, and the key, *k*, to the Down line. The electro-magnet being excited pulls up the lever, *a*, and the end of the latter disengages from the balance-wheel, B, and allows the clockwork mechanism in connection with B to run. Attached to the lever, *a*, is a toggle, *t*, which tends to move to the left under the influence of the spring, *s*. As soon as the lever, *a*, is lifted up, the projecting piece on this toggle hitches over the stop, *e*, being drawn over it by the spring, *s*, so that when once attracted, the lever, *a*, is unable to fall back to its normal position and stop the balance, B, the clockwork, therefore, will continue to run. The end of the toggle, *t*, it will be seen, touches against the right hand side of an arm, c_1, which arm is fixed to the axis of the wheel, *w*; now the length of the end of the toggle is such that if the latter is just hitched on the stop, *e*, this end would not quite clear the arm, c_1; if however the toggle is raised a little higher, then the end will clear, and as *t* is pulled to the left by the spring, *s*, it follows that when *t* is lowered until its projection banks on the stop, *e*, the end of *t* will come down on the *left* hand side of c_1, so that *w* can revolve without obstruction. The limiting stops of the lever, *a*,

are so adjusted that the movements referred to can take place as indicated.

Let us, then, suppose that the lever, *a*, has been raised and released again so that the toggle, *t*, has become raised over the end of c_1, and let down on the left hand side of the latter, and that *t* has become hitched on to *e*, so that the balance-wheel, B, is free to move and the clockwork mechanism to turn, then the wheel, *w*, which revolves once in a minute like the wheel, *w*, in fig. 4, rotates until the arm, c_2, comes round in contact with the end of the toggle; the latter is then pushed off its stop, *e*, and allows the lever, *a*, to fall and lock the balance, B.

Now the arm, *g*, which is also fixed to the axis of *w*, in the course of its rotation comes in contact with the spring, S, and if it should happen at that particular moment that a second current is sent through the line, then this current will divide, part passing through M, and actuating the lever, *a* (this movement, however, effecting no change in the condition of affairs), whilst the other half of the current (dotted arrows) passes through the magnet, *m*, of the Bell, and by releasing its mechanism causes it to sound. If however the current should come either *before* or *after* the arm has made contact with the spring, then this current cannot pass through the Bell.

Now we have seen that the interval of time which elapses between the transmission of a current by the depression of the stud, *p* (figs. 1, 3, and 4), and the transmission of a second current by the arm, *n* (fig. 4), can be regulated by the pointer, *h* (fig. 3), if therefore the contact springs, S, on the instruments of subscribers 1, 2, 3, 4, 5, 6, and 7, are so arranged that when the mechanisms of all the instruments are set going the first contact is made in instrument 1, the second contact in instrument 2, the third in instrument 3, and so on; and further, if the positions of the springs are so adjusted that the interval of time intervening between two successive contacts is the same in every case, then it is evident that if the pointer, *h* (fig. 3), be set at, say, division 5, then the contact made by the arm, *n* (fig. 4), will be made at the same time that contact is made by the spring, S, on the instrument of subscriber 5.

Attached to the wheel, *w* (fig. 5), is an indicating disc, w_1 (*see* figure at side). This disc is divided into twelve divisions, six white and six red. This disc is set behind the aperture W_1, seen in fig. 6, which has openings cut in it, so that when the disc makes a twelfth of a revolution the red spaces disappear, and the white take their place, or *vice versâ*.

In the position of the apparatus shown in fig. 5, the white portions of the disc appear (showing that the line is clear), and the same will be the case if the arm, c_4, or arm, c_5, be touching the toggle, *t*. If, however, either arm, c_2, c_3, or c_6, be against *t*, then the red portions will be exhibited (showing that the line is occupied).

It has been explained that when a subscriber calls the central exchange station he depresses his call button, *k*, fig. 5, and sends a current. The effect of this is to cause the lever, *a*, fig. 5, in each instrument on the circuit to be attracted, and to set the clockwork mechanisms in action. When arm, c_2, comes round, it unhitches the toggle, *t*, off the stop, *e*, on which it has been lifted and stops the train of clockwork; consequently the red of the discs in each instrument will be exhibited, showing that the line is occupied. As the dropping of the indicator at the central station has disconnected the circuit, no second current can be sent by any subscriber, and consequently the discs being once set at "line occupied," cannot be changed to "line clear," by any one but the central exchange.

Supposing now that the apparatus at the central office is connected to line 1, the pointer set at the number of the subscriber it is required to call, and the push, *p*, depressed, then a momentary current flows out to line, which sets the mechanisms of all the instruments on the circuit in motion, and, as has been explained, causes the bell of the required subscriber to sound; when the mechanism has come to rest, one of the arms, c_3, c_6, or c_2, of the wheel, *w*, in each instrument will be against the toggle, *t*, and consequently the discs will show "line occupied."

After the allotted time for the subscribers to communicate has expired, the apparatus, fig. 3, at the exchange station is conducted to line 1, as was explained at the beginning of the article, and the button, *b*, depressed once, so as to send a momentary current to line; this causes the levers as in each subscriber's instrument to be attracted, and the mechanisms to be released; but these are almost immediately stopped by the second arm, c_4, c_5, or c_1, in each instrument unhitching the toggles; the small angular movements of the discs change their indicators to "line clear." The apparatus, fig. 3, is then connected to line 2, and the same operation is gone through.

The "clearing" current, it will be observed, could be sent equally well by depressing the stud, *p*, instead of the button, *b*; but inasmuch as the apparatus could not be transferred from line 1 for use on line 2 until the clockwork mechanism set free has come to rest, it is preferable to employ the button, *b*.

It will be understood that the switch arrangement, S", shown in fig. 5, has attached to it other connections for bringing the usual telephone transmitting battery, transmitter, and induction coil into circuit, but these connections have been left out in the figure to avoid confusion in the important parts of the illustration. These connections being purely local, in no way affect the action of the indicating apparatus.

From the explanations which have been given it must be evident that the invention of Mr. Kettell possesses amongst other advantages one very important one, and that is that the apparatus is self-adjusting. If by any chance it should happen that a signal should fail from a fault in the line wire or from any other reason, the instruments do not require any resetting; this is not the case with other inventions which have been brought out for similar purposes. The mechanism is not at all liable to derangement and does not require heavy battery power to work it, the function of the latter being merely to release the wound-up mechanism, and not to drive it.

The number of revolutions which the wheels, *w*, *w* (figs. 4 and 5), would have to make in a day is so very small that the mechanism would run for a very lengthened period without requiring to be wound up. In the case of the alarum bell this winding up would have to be done more often, but as there is a small indicator ("Wind" fig. 6) connected to the work which shows when the rewinding is required the wheel-inconvenience of the clockwork running down and the bell ceasing to act is not likely to arise.

NEW ELECTRIC LIGHT COMPANIES.

WE notice in the daily press of the present week the advertisement of a new electric light company, and a preliminary notice pending the formation of another. These are respectively the "J. B. Rogers electric light and power," and the "Electric Sun lamp and power" companies. Up to the present we have not considered the electric inventions of Mr. J. B. Rogers of sufficient importance to occupy much space in our columns, and we have only referred on one or two occasions to the various reports which have appeared in certain journals relating to them. Now that a company has been formed for working the numerous patents, English, foreign and colonial, of Mr. Rogers, we purpose making a few remarks in the interests of both electrical engineers and the public. The prospectus, after stating for what purpose the company is promoted, and making a point of its being a parent company, goes on to say,

> The subdivision of the electric current has hitherto been the great desideratum, and the fact that Mr. Rogers obtained the first patent for a system of sub-division, dated 20th September, 1880, which is prior to any other patent for this specific purpose, shows that he was one of the earliest workers in this direction.

This so-called subdivision of the *electric current*, we need scarcely say, has been known as long as the current itself, which is therefore some years before Mr. Rogers began his scientific investigations on the subject of electric lighting. Now, if such a patent could be called valid, why, then, Mr. Werdermann stands some time before the Rogers patent of 1880. The matter contained in this specification, of what we will call out of courtesy an invention, was brought prominently forward by *Iron* on several occasions, and some of the daily newspapers also spoke very highly of the system. It would hardly be fair on our part to stigmatise this portion of what the J. B. Rogers vendors are promoting

as we at first felt disposed, because Mr. Rogers himself, the vendors, *Iron*, and the rest *may* actually believe that there is something in it, and that the patentees' copper globes are really other than "multiple binding screws." We, however, solemnly and sincerely declare our belief that the magic properties of these metallic globes or cups exist only in the imagination of those we have quoted, and that a very near approach to the results of Mr. Rogers has been obtained by Messrs. Edison, Swan, Lane-Fox, &c., independently of such aid.

It may be, however, that we are wrong, for we notice our monthly electrical contemporary gravely states the following :—

> Put broadly, the system amounts to this: Mr. Rogers charges—we must not use the word accumulates or stores—the electricity into certain vessels, something like a large ball-cock of a cistern, and literally taps them to supply practically any number of incandescent lamps. Incidentally it is only fair to Mr. Rogers to say that, having some knowledge of, and respect for, the English tongue, he uses the word "accumulates" purely in the sense of "gathering together," and not in the sense of "storing," as understood and used by modern electricians.

We must, even in the face of this authority, still hold our own opinion, based on the hardly gained experience of many, many years, that an installation of the electric light on the Rogers system might be rendered somewhat less costly and less liable to derangement outside a laboratory or office, were the dividing boxes left out of the question.

We do, however, believe that Mr. Rogers has in action a very good incandescent lamp, but what claims are set forth in the patent for this we cannot say, as we believe the specification has not yet been published. In the schedule attached to the prospectus there are nine different patents, including the one we have just referred to for *division* and *subdivision*. As far as we are aware the patents for incandescent lamps, accumulating and storing electricity, and dynamo-electric machines, have only been applied for since the beginning of February of the present year; it is, therefore, impossible for us to comment on five out of the remaining eight. That the public is prone to look upon anything for which a small sum is asked as worthless is well known, the price, however, required by the vendors of these patents, which, according to the prospectus, go to make up a complete system of electric lighting, is £40,000 in cash, 12,000 fully paid-up shares of £5 each, and 2,000 deferred shares of £5 each, the capital of the company being £510,000 in 100,000 preferred shares and 2,000 deferred shares of £5 each respectively. We may incidentally remark that, besides the patent of 1880 mentioned in the prospectus, there are now published the following specifications of Mr. Roger's electrical inventions: Nos. 1922, 4854, and 4855, this last having for its object the production of the *arc* and *incandescent* light in the *same lamp* and by the *same carbons* at will, so that the light may be changed from one to the other by a simple movement.

Seriously we do not desire to say anything respecting this company of a harsh nature, for it may be that Mr. Rogers really believes he has discovered actual improvements in electrical science; but from what we have seen and heard for ourselves we could not in justice to electricians with *bonâ fide* inventions, or to the investing public, recommend a system of so-called division and subdivision concerning which the most ridiculous and misleading statements, it has ever been our lot to notice, have been noised abroad.

The second company to which we have called attention is apparently following the example set by the Fyfe-Main arc lamp promoters. Perhaps the result will be the same, but for the future gain of electric lighting we hope not, as so simple and inexpensive a lamp as the "Sun" deserves to make headway.

THE RED SEA CABLE.—We understand that Messrs. Siemens Brothers & Co. have chartered for the laying of that cable the ss. *Rochefort*, belonging to Messrs. John Cory & Co., of Cardiff. The *Rochefort* is a screw steamer, 220 ft. long by 31·2 ft. beam by 15·6 ft. deep, of 874 tons gross, and 99 horse-power. She is now moored off Messrs. Siemens Charlton, where she is being fitted with the necessary machinery, &c., for this kind of work.

INFLUENCE OF ELECTRIC CURRENTS UPON EACH OTHER.

WE think that very little information is ever to be found on this subject beyond that in certain text books, mostly belonging to a bygone age. As it is a question of considerable importance to electrical engineers, and as it can now be studied with much stronger currents than have heretofore been possible, we propose to occasionally devote a portion of our columns to the purpose of bringing the matter before electricians engaged in the practical work of electric lighting, believing that they may be able to materially augment our present knowledge by experiments of their own. The discovery made by Œrsted that *an electric current transmitted near to a magnetic needle deflected it from its normal position* excited throughout the scientific world the liveliest interest. New facts were experimentally sought for in order to prove the identity of electricity and magnetism, or to show that they were both only different examples of the same fundamental force. Electrical engineers now have opportunities for studying these effects in a

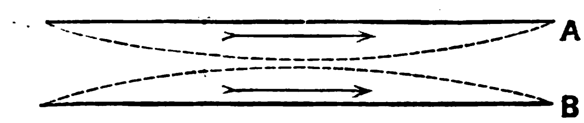

FIG. 1.

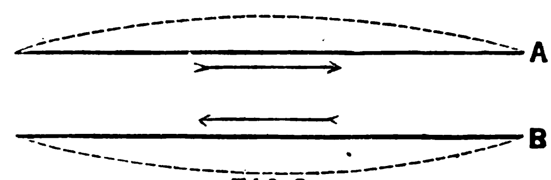

FIG. 2.

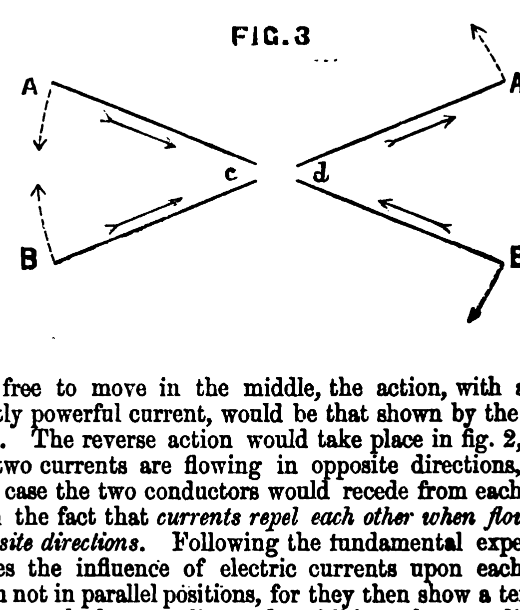
manner, and with means beyond anything available in the days of Œrsted and Ampère. It is well known that the latter philosopher found that the influence of electric currents on each other varied with position and direction, and the following is the fundamental law according to which these different influences act :—*Parallel currents attract each other when they flow in the same direction.* In fig. 1, A and B represent two conductors in which currents are flowing in the same direction, as indicated by the arrows. Were these conductors free to move in any direction, they would close up together, or if they were fixed at two points

FIG. 3



and free to move in the middle, the action, with a sufficiently powerful current, would be that shown by the dotted lines. The reverse action would take place in fig. 2, where the two currents are flowing in opposite directions, for in this case the two conductors would recede from each other, from the fact that *currents repel each other when flowing in opposite directions.* Following the fundamental experiment comes the influence of electric currents upon each other when not in parallel positions, for they then show a tendency to approach the same line and to fall into the same direction on that line.

If we take two currents, A *c*, B *c* (fig. 3), both flowing towards *c*, and forming whatever angle, the tendency will

be for the two conductors, from the example given in fig. 1, to approach each other, as shown by the dotted lines. This attraction would of course take place if the two currents were flowing from *c*, instead of towards it; repulsion takes place when one current is going in the direction *d* A, and the second in the opposite way, B *d*. We are feign to believe that now we are able to produce such powerful currents by means of dynamo-electric machines, some of our electrical engineers will devise a means of still further simplifying the lamps used in electric lighting by the aid of the attraction and repulsion of electric currents. At present we can call to mind but one practical application of this force, viz., the candle of M. Jamin. This well-known French *savant* took advantage of the fundamental law before mentioned to keep the electric arc at the tips of the parallel carbon pencils forming his candle; but some time before M. Jamin's invention, Mr. Robert Sabine had devised and taken out a provisional specification for electric lamps, in which the attraction and repulsion of currents were made, not only to keep the electric arc at the ends of two parallel rods of carbons, but these were also arranged in such a manner in connection with thick copper conductors, that the repellant force of the currents used was of sufficient strength to part the carbons automatically, and the distance between the carbons varied as the intensity of the current. We well remember assisting at the experimental trials of three different forms of electric lamps devised by Mr. Sabine and based on this principle, the results of which were at least encouraging, although the facilities for working at that time were not so great as at present. Perhaps another reason why these experiments were dropped was the fact that they were somewhat in advance of the times, there being little demand for, or encouragement to invention in electric lighting. We have brought the matter forward in the hope that it may suggest ideas to the many inventive minds now centred on perfecting this most useful of modern necessities.

MESSRS. SIEMENS AND HALSKE'S SELENIUM PHOTOMETER.

MEASURING instruments have always played an important part in electrical researches. The rapid progress of this new science, bringing into notice every day the discovery of phenomena hitherto unobserved, has in fact necessitated all throughout, methods of measurement better adapted to the nature and importance of the effects observed. Thus, these instruments were neither the least numerous nor the least interesting among the various models shown at the International Exhibition of Electricity. As marvels of invention, and the greater number at least as masterpieces of delicacy of construction, they justly ranked high in that great scientific and industrial display; but they derived their importance chiefly from the necessity of checking incessantly the results obtained, thus confirming one by the other the great laws which govern electrical phenomena throughout.

This apparatus, which is merely mentioned among M. J. Reynaud's notes, appended to his translation of Gordon's "Experimental Treatise on Electricity and Magnetism," is based on the variations of the electrical resistance of selenium under the influence of light. Among the very remarkable, but as yet illdefined, electrical properties of selenium, there is one which is known to everybody, viz., the diminution of its resistance under the influence of light. When subjected to different radiations, selenium does not seem to be influenced by the rays of heat, whereas the maximum of the effect produced upon its resistance seems to correspond to the maximum of light (between yellow and green). From this it follows that a comparison of the intensities of any two sources of light, based upon the variations of resistance in this substance, can only be exact when lights of the same colour are compared. This condition is expressly stated by the inventors of the selenium photometer, who have endeavoured to utilise this curious property as far as possible in the ingenious apparatus of which we are now going to give the description and the method of using.

DESCRIPTION.

The instrument consists essentially of two distinct parts: a galvonometer and the photometer properly so called.

Galvanometer.—The galvanometer is a Thomson portable galvanometer, G, fig. 1, with a single coil, in the middle of which a tube of copper, containing the mirror, slides easily. This mirror, concave in form, very light, and furnished with little magnets which distinguish it, is suspended in the tube by the top and bottom, by means of very short fibres; a little glass cap closes the tube in front of the mirror, and a screw placed at the back of the tube enables the mirror to be held fixed for packing or to be left free to swing; its oscillations can besides be slackened and thus the instrument is made into a dead beat galvanometer. A magnet, N, fig. 1, enables the influence of the terrestrial magnetism to be withdrawn, and thus the sensibility of the apparatus is made to vary.

This galvanometer is mounted on the same stand as a petroleum lamp, L, protected by an inclosure of sheet iron. Opposite to an opening in front of the inclosure and with a

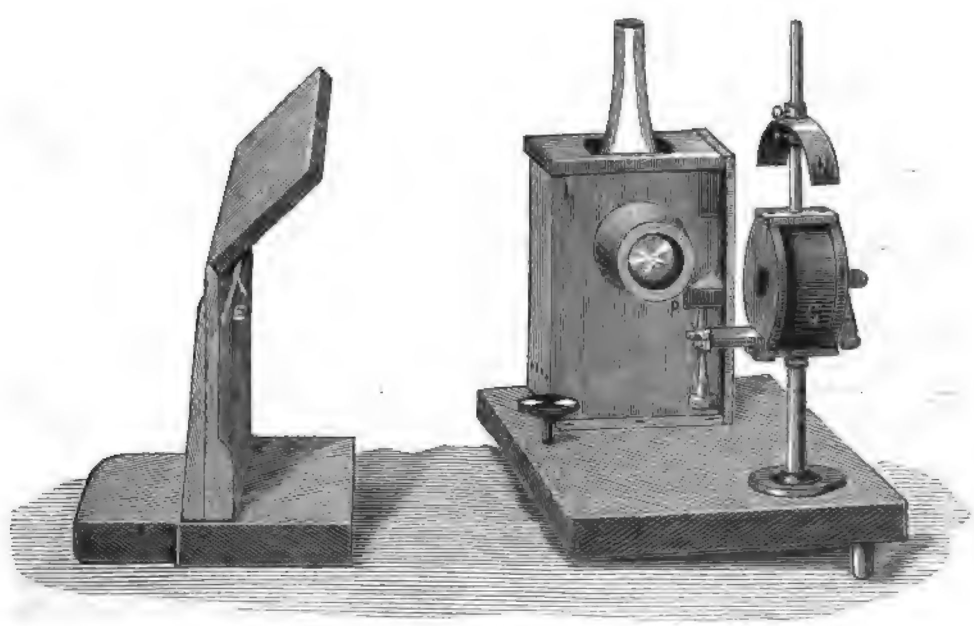


FIG. 1.

vertical cross wire between is placed a lens, which collects into a luminous sheaf the rays sent out by the lamp. The galvanometer and the lamp are arranged at right angles to one another on the stand. A prism, with total reflection, P, is placed over the galvanometer and supported by a stand which allows of it being adjusted to the position required. The luminous beam sent out by the lamp is received on the prism and sent back by it on to the mirror, which in its turn reflects it on to a divided scale, E, which is independent of the galvanometer and which can be drawn back or brought nearer at will in order to obtain clearness in the reflections.

In order that the prism with total reflection may not intercept the ray reflected by the mirror when the deviation is somewhat considerable, it must be placed a little lower than the mirror, and the reflecting surface must have the inclination required in order that the light reflected at first on the upper part of the prism may then fall on the mirror and pass on its return a little above the reflecting prism.

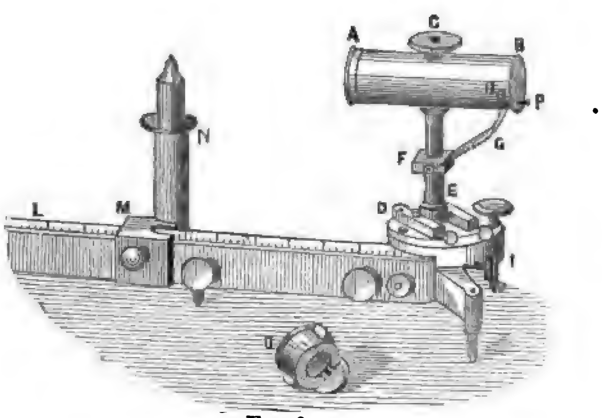

FIG. 2.

Photometer.—The photometer properly so called (fig. 2) consists of the selenium tube and of a graduated rule along which the luminous source taken as standard can move. The selenium tube is a tube of copper, A, B, 0^m. 03 in diameter and about 0^m. 15 long, blackened inside and mounted perpendicularly on a support movable round its vertical axis. This support is terminated at the bottom by a circular base, furnished with three horizontal branches with feet, which serve to keep firm the apparatus; of these three feet one, I, is screwed and allows of the position of the system being regulated.

On the circular base of the support are placed two horizontal terminals, D, E, insulated from the rest of the apparatus and only in communication with a circular metallic socket in the middle of which the support turns. In the latter is fixed a little plate of ebonite, F, with a metallic cincture, to which are fixed two contact springs, which insure electrical communication with the socket and the lower terminals in every position of the support.

The copper tube, A, B, open at both ends, can receive at one of its extremities, A, a metallic cap with a circular diaphragm, and at the other extremity, B, either a cap containing a screen with a cross wire, or the selenium box shown at O at the bottom of the diagram. This selenium box is made of horn and slides easily into the opening, B, of the cylinder. It contains the plate of prepared selenium sheltered from the light by a little slide, which is opened or closed at will on the apparatus by a little button shown at P. It is besides furnished with two little terminals, H, connected to the plate of selenium and insulated from the rest of the system; two insulated wires, G, coiled in a spiral, put these terminals, H, in contact with the two springs, and the lower terminals in all the positions of the tube, A, B, which is moved by the top button, C.

From this description it follows that a battery current arriving by one of the terminals, D or E, will pass through one of the contact springs, one of the wires, G, and one of the terminals, H, to the plate of selenium, and will return by the corresponding course to the other terminal, E or D, following, besides, all the movements of the tube, A, B.

On one of the horizontal branches of the tripod is fixed a scale, also horizontal, one metre in length, the zero of which is in the vertical plane passing through the selenium plate. Along this divided scale slides a runner, M, bearing the candlestick in which is placed the standard light. This light is maintained fixed at the height of the axis of the tube, A, B; its axis is in the vertical plane passing through the joint where the reading is taken, which allows its distance from the plate of selenium to be measured exactly.

We can, also, by means of the screw shown near I, in the foot of the apparatus, limit at will the course of the tube A, B, in the horizontal plane, and bring it without difficulty into such a position that the standard light may be in the prolongation of its axis.

MODE OF EMPLOYMENT.

Installation of the Galvanometer.—The scale is placed beyond the direct action of the lamp, and in such a manner that the middle of it may be about in the direction and at the height of the axis of the galvanometer, at a distance of at least 0^m. 5 from it (fig. 3).

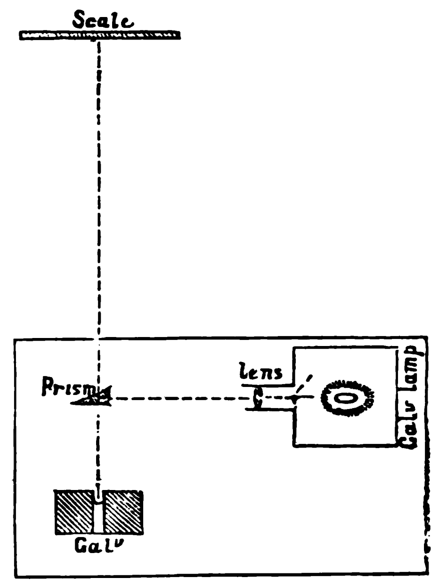

FIG. 3.

Into the coil of the galvanometer is introduced the copper tube containing the mirror with magnets, and it is adjusted in such a manner that the suspending fibres of the mirror which serve as an axis of oscillation may be about vertical.

The plane of the flattened flame of the petroleum lamp is made to coincide with that passing through the network and the centre of the lens (fig. 3). In order to arrive at it, we begin by taking away the prism appended to the galvanometer, so that the luminous ray of the lamp may fall freely on a sheet of white paper placed at a distance of one to three metres, so that by a suitable displacement of the lens a shadow of the wire may be obtained. The lamp is made to slide until the shadow of the wire no longer presents chromatic edges.

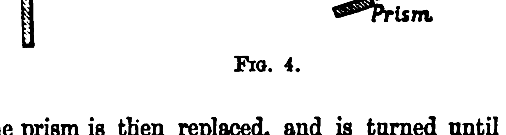

FIG. 4.

The prism is then replaced, and is turned until the reflected ray falls on the mirror with magnets, which is ascertained by looking directly at the mirror. The course of the reflected ray is then followed by the mirror, by means of a sheet of paper on which the ray is let to fall, and the prism is fixed in such a position that the light reflected by it falls in the middle of the mirror, and that the ray sent back by the latter passes back directly above the prism (fig. 4). By turning the screw, V, which is shown on the stand of the galvanometer (fig. 1), the ray is then brought to the height of the scale, and by causing the position of the directing magnet surmounting the galvanometer to vary,

it is made to arrive at any required division of the scale. Finally, the lens is made to slide until the shadow of the wire reflected on the lens is quite clear, and the tube of copper containing the mirror is turned until the shadow moves horizontally along the scale.

By raising or lowering the directing magnet, we increase or decrease at will the sensibility of the galvanometer, which can besides be arranged in any plane whatever.

In the lantern, for the objective in which the wire is stretched, we can substitute another, forming a diaphragm in which a vertical slit is made.

Employment of the Photometer.

The selenium photometer is adjusted in such a manner that the movable tube, when it is perpendicular to the scale, may be directed towards the luminous source, the intensity

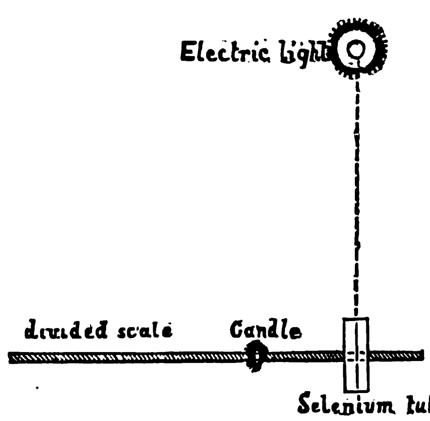

FIG. 5.

of which is to be measured (fig. 5). In order to arrive at this, the horn box containing the plate of selenium is taken away, and for it is substituted the socket, transparent at the bottom, with a cross wire, the front part of the tube being closed also by the diaphragm with the hole in the centre. The photometer is then turned in the direction of the luminous source until the shadow of the hole is projected on to the middle of the cross. Then the two abovenamed caps are taken away and the one at B is replaced by the selenium box.

These operations having been performed, we connect in one circuit the galvanometer, the plate of selenium, and a battery of 12 or 24 elements, which is filled with acidulated water, but not put into action until the moment for its employment.

As soon as the circuit is closed, a deviation of the galvanometer is observed, and the spot of light often goes off the scale; by adjusting the directing magnet, the reflection is brought back within the limits of the scale.

Under the action of the light, the resistance of the selenium decreases, and consequently the deviation of the galvanometer produced by the current increases. The plate of selenium is exposed to the light by the open portion of the tube which is turned towards the luminous source to be measured, and by the opening of the little valve of the selenium box adjusted at the other end of the tube.

We observe the deviation of the mirror corresponding to the resistance of the selenium influenced by the light; then, by causing the selenium tube to make exactly a quarter of a revolution—regulated by the screw, I (fig. 4)—it is directed towards the standard light, and the slide, M, is made to slide along the divided scale until the same deviation of the luminous point is obtained as before. By directing the selenium towards first one and then the other of the luminous sources, observing the corresponding deviations, and causing the distance of the standard light to vary along the rule, we find the distance at which the two sources of light produce the same effect on the selenium. These variations of resistance are very rapid. The distance of the plate of selenium from the light to be measured being known, and the luminous intensities being in inverse ratio to the squares of the distances, a simple reading of the divided scale enables the relative lighting power of the light studied to be deduced immediately. But, as we said at the commencement of this article, the selenium photometer is only strictly accurate when lights of the same colour are compared.

[This article was written for *La Lumière Electrique*, by M. E. Boistel, who is, we believe, the manager of Messrs. Siemens Brothers' establishment in Paris.]

THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

ON the 11st inst., by the kind permission of Brigadier General Sir Evelyn Wood, V.C., G.C.M.G., K.C.B., commanding the Chatham District, and of the Commandant of the School of Military Engineering, Chatham, a reception was held at the latter place by Lieut.-Colonel Webber, R.E., the president of the above society. A large number of guests availed themselves of the invitation. After a luncheon at the Royal Engineers' officers' mess, a short lecture on torpedo warfare was delivered in the theatre by Major ARMSTRONG, R.E. The lecturer explained the various systems of torpedo defence at present in use. The firing of the fuses was either accomplished by low or high tension electricity. In order to make a clear distinction in the apparatus, that which was employed for low tension firing was coloured white; this included the various cases for holding the explosive materials. The apparatus, &c., for high tension firing was all coloured black. By this arrangement the various kinds of stores were not liable to become mixed up accidentally. The cases containing gun-cotton were partially painted red as a distinguishing mark. The nature of gun-cotton was explained by experiment, and it was shown that a form of the cotton which would only burn silently when ignited by the direct action of flame, could be exploded by a detonating fuse. The action of the "contact makers" in floating torpedoes was pointed out and practically illustrated. Major ARMSTRONG, in alluding to the exhibit by the War Department of torpedo apparatus at the Crystal Palace, said that the display might have been much greater if it had not been considered unadvisable to make too public many of the inventions devised.

The guests were next conducted over the schools of electricity, photography, chemistry, architecture, &c., and were also shown the various field operations, such as bridge and earthwork construction, the demolition of railway tracks, the firing of mines, both under water and under ground, the former especially producing a very magnificent effect.

The impression given was that the whole system of practical military instruction was very complete. It is, perhaps, needless to state that the whole party were much pleased with their visit, and with the extreme courtesy they received from the officers of the corps.

CORRESPONDENCE.

TO CORRESPONDENTS.

Correspondence should arrive not later than Tuesday morning if it is desired to appear in the following number.

FIRE RISKS FROM THE ELECTRIC LIGHT.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Can you find room for the following sketch of the certain consequences attendant upon the carrying out of the wonderful sections 8 and 9 of the regulations for the prevention of fire risks arising from electric lighting? Of the other sections I can but express my astonishment that such an eminent assemblage of scientific men should have deliberated to so little purpose and produced nothing but commonpla-

phrases. It is evident that not one practical man was asked for an opinion.

Scene, large jeweller's shop in Bond Street; time, afternoon in the month of November, a regular black fog outside, electric lights turned on (fitted up according to the 21st section of the regulations against risk by fire), and very much to the satisfaction of the proprietor, making him feel very safe. Enter lady, stylishly dressed. Shopman, bowing and rubbing his hands, either from custom or cold (the electric light doesn't give out any heat):

"What can I have the pleasure of showing you to-day, m'am?"

Lady: "I should like to see some diamond parures."

Shopman brings out some six cases of magnificent ornaments, and inwardly chuckles that the electric light has "fetched" this customer.

"Magnificent! unrivalled!—worth 4,000 guineas; the Duchess of S—— can't match them."

Sections 8 and 9 take effect. The shopman hears the rustling of a dress, the creaking of a door. The consequences flash across his mind and he rushes round the counter, over a judiciously-placed chair, with his proboscis against a plate-glass case. With the shock the five words—"D— the rules and regulations!"—are jerked out of him. £10,000 are gone! Electric light companies are at a discount, and dear old Gas taken into favour again.

The committee must have slept the last four years. What has been the aim of all electricians? To make the light reliable, and here are rules, framed by clever men, to make what has been accomplished nugatory.

Your leader is sensible and in the right direction; it is a pity the committee couldn't have it before their eyes; we should then have been spared such a poor exhibition.

I remain, Sirs,
Yours obediently,
E. A. PARIS.

Shepherd's Bush, W., *July 8th*, 1882.

A NEW USE FOR INCANDESCENT LAMPS.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—It is a well-known fact that in many countries night fishermen use lights to attract the fish towards the nets or other appliances for catching them. To carry this idea out to perfection, our fishermen must have an incandescent lamp (supplied from an accumulator carried in their boats), attached to the nets as they cast them into the water. It is a very common occurrence for one of our fishing boats in Scotland to catch in a single night herrings to the value of one hundred pounds, and I think I am correct in saying that a special committee appointed lately to inquire into fishery matters, agreed from evidence that there were as many fish in the sea now as in the days of our forefathers, so that there seems to be no fear of the supply running short. Would it not, therefore, be wise for some enterprising individual or company to make experiments in this line?

Speaking from some knowledge of both subjects, I believe the idea to be a perfectly practicable one.

I am, yours faithfully,
DENSHIN.

ELECTRIC LIGHTING FOR STREETS.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Touching remarks by Col. Haywood on the lighting of the Holborn Viaduct by the Edison Incandescent Light, I would observe that I presume the Colonel likes the lighting because it is very "gas-like," save that the latter has the advantage. I consider the Viaduct far better lighted by gas than by the small electric lamp. The spoiling of walls and furniture does not here apply, and the two being nearly equal in illuminating power, gas is decidedly the best for the purpose; but in the matter of street lighting, we want more light—very much more light. Same applies to railway stations; and I may here mention that since the District Railway at Charing Cross has been lighted by electricity no accidents have occurred; prior to such they were not unfrequent—I allude to passengers stumbling in getting in and out of the train for want of sufficient light.

Over near three years ago the Holborn Viaduct was lighted by the Jablochkoff system. Col. Haywood then pronounced it beautiful, but too expensive. At *that* date it cost 6½d. per light per hour: same price was charged the Metropolitan Board of Works for the Embankment. Excessive cost caused the City authorities to discontinue the light; the Board continued, and, by a gradual reduction, have now arrived at 1½d. per light per hour for a lamp giving 380 candle-power. The street lamp gas-lighted costs ¼d. per hour for 10 candle-power. The calculation is easy.

If the Holborn Viaduct is to be lighted by electricity let it be by an arc lamp, by which much more light will be afforded; not by an electric light which in every feature as nearly as possible resembles gas. We live in an age of improvement, and desire to be further enlightened. By all means let us have Sugg's grand burner, if not too expensive; but do not attempt to light great thoroughfares by an electric lamp which in candle-power is not superior to the ordinary gas-lamp of the past decade.

ELECTRON.

July 11th, 1882.

DOLBEAR TELEPHONE: A CRITICISM CRITICISED.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—In a recent number of this journal (June 24th) an article appeared from *La Lumière Electrique*, in which Count du Moncel takes occasion to criticise a paper read March 23rd, 1882, by Prof. A. E. Dolbear, before the Society of Telegraph Engineers.

Prof. Silvanus Thompson has, in the 1st July issue, very ably responded to a part of the statements made by the Count du Moncel, viz., that part relating to the early history of the Reiss telephone. There are also other statements of the Count which it does not seem desirable to have remain unchallenged.

In conclusion he says:—"But I think it is as well to remark that 'Mr.' Dolbear, in calling his apparatus a novelty is in error. In the first place, the production of sounds by a condenser was not new, inasmuch as Mr. Dolbear himself, in his historical account, alludes to it, and what would be new would be the possibility of reproducing speech in this way; but it is Mr. Herz who obtained this result first, at the commencement of the year 1880."

The fact that sounds may be produced by a condenser having been widely known for so long a time, it seems strange that a writer upon scientific subjects should think it necessary to state that the idea is not a new one. As the writer understands the claims of Prof. Dolbear they are as follows:—(*a*.) The first to conceive the possibility of reproducing speech by means of condensers. (*b*.) First to accomplish it by experiments. (*c*.) First to produce a practical speaking telephone founded upon those principles. These claims are still maintained.

In reply to this the Count says, "But it is Mr. Herz who obtained this result (the reproduction of speech) first, *at the commencement of the year* 1880."

This remarkable statement assumes, 1st, that its author is well aware of the time when Prof. Dolbear first accomplished this; and, 2nd, that it was done at a date subsequent to the one above mentioned.

As a matter of fact the Count du Moncel knows nothing of the kind; nor has he ever had any adequate means of knowing.

It behoves the noble Count to be more cautious how he indulges in such unguarded statements. The "impartial historian" does not assume facts and draw conclusions therefrom which suit his own convenience, nor will *such* conclusions ever receive the title of "*legal perorations*."

Granting that the experiments attributed to Mr. Herz were made, as stated, as early as the commencement of the year 1880, the work was not new.

The Dolbear condenser telephone dates are prior to that; indeed the instrument was even then in almost, if not quite, its present perfected shape.

Very many persons had admired its clear and perfect enunciation.

Business men had become interested in it previous to this time and had embarked in the enterprise of bringing it

into public use. Precautions were taken to have ample proof of all this, with signatures and dates upon apparatus with properly certified affidavits, &c., &c.

For the present, for reasons which already appear to have been good and sufficient ones, those dates are withheld. But all the evidence and much more will at the proper time and place be produced. We all know how easy it is to have some abandoned experiment or vague idea recalled by the ultimate success of that idea. To illustrate :—

The Count says—"On June 2nd, 1875, Mr. Bell had thought of this substitution (permanent magnet for electro-magnet), and if this *savant* had not put this into practice in the apparatus exhibited by him at Philadelphia, in June, 1876, it is because he expected to obtain more powerful effects by a system in which the magnetic organisation was formed by an electro-magnet (strongly magnetised by a continuous current) than by a system formed by a simple permanent magnet of steel." Granting, for the time, that Mr. Bell did in June, 1875, conceive the idea that he could use a permanent magnet *in place of a battery*, that idea was, after deliberate reasoning, abandoned by its author as worthless.

This *lost idea* added nothing to the sum of human wisdom. It might as well never have been—indeed better; because it leads to a fixed erroneous opinion. Such opinions, like false theories and formulæ in science, are only productive of evil.

In order that Mr. Bell might recover this idea, one of two things must first happen. Its truth must be forced upon him by accident during his experiments or, having obtained a more complete knowledge of his subject, he must, with the new data, reconstruct his previous opinions. It is generally admitted that abandoned experiments are to be disregarded, because of no use to any one. How much more so an abandoned idea which its author discards. One is reminded of the drowning man and the straw when such claims are woven into what purports to be an historical fabric.

As the second earliest experimenter in this unique line of discovery, Count du Moncel brings forward Mr. Dunand in the following words—"Mr. Dunand, of whom Mr. Dolbear was so careful to speak, in the month of September of the same year, obtained very important results in consequence of principles precisely contrary to those laid down by Mr. Dolbear. Thus, by means of eleven small condensers, formed of sheets of paper of small dimensions and very numerous, joined up in quantity and arranged fan fashion, he succeeded in transmitting speech sufficiently powerfully to be heard at a distance of two or three metres from the instrument. It is true that he employed two batteries, one of which, that destined to polarise the plates, was very powerful; but these experiments show that the theoretical ideas of Mr. Dolbear cannot be accepted without great reserve."

It is not worth while at the present time to discuss the *molecular* and *mass motion* theories for explaining the action of telephonic diaphragms; however, notwithstanding the Count has for years diligently advocated the former, very many, and probably the majority of eminent physicists believe the latter to be the true explanation.

Another of Prof. Dolbear's *theoretical ideas* is as follows:—

"In my opinion the greater the number (of plates) employed the less effective will be the telephone of this kind."

That opinion was the result of long series of experiments many times repeated, and under all conceivable conditions. The Count states, as something astonishing, that speech could be heard *two* or *three metres*, although he admits that the apparatus was somewhat elaborate. Prof. Dolbear says, in that very communication, that he has been enabled to hear speech at a distance of 50 ft. The writer can assure the readers of this journal that the Professor's statement was far within bounds, as could be testified by hundreds who have heard it at that distance. Doubtless Mr. Dunand has done some excellent work in this line; but it is yet to be shown that he is a pioneer in the business.

In referring to the practical use of any telephonic system, even at the present day, Prof. Dolbear took occasion to say that it is necessary to inclose the instrument in a case in order that the air waves might be concentrated upon the ear. Touching upon this point, the Count feels "obliged to say to 'Mr.' Dolbear that there exist telephonic receivers which are susceptible of being heard at a distance!" To one familiar with the immense number of experiments which Prof. Dolbear has performed in this line, with all kinds of, and systems of, apparatus, and in the light of the astonishing results which he has obtained the statement which Count du Moncel feels obliged to make to "Mr." Dolbear is ludicrous in the extreme.

By the way, why is it that the eminent Count, who is generally so courteous, fails to give him his usual title? Prof. Dolbear has for many years occupied a professor's chair in the highest educational institutions in America.

If Count du Moncel will write with a fair and unbiassed pen, the eminent men belonging to the Society of Electrical Engineers, many of whom have ever shown the liveliest interest in original scientific work from every source, will, doubtless, be only too willing to have him eradicate that "complete ignorance" of the host of distinguished *savants* who have occupied themselves in the question of the telephone.

I trust the time will come when Count du Moncel will not display either a "real or voluntary" forgetfulness of the just claims of any one.

HENRY C. BUCK.

NOTES.

TELEPHONE EXCHANGE CALL SYSTEM.—Through the courtesy of Mr. G. Edward Smith, of Boston, Mass., United States of America, we are enabled to give a full description (see p. 24) of a telephone exchange call system, the invention of Mr. Kettell, of Worcester, Mass., U.S.A., which enables a number of subscribers to be put in communication with a central exchange by means of one wire only. The apparatus is considerably in advance of anything of the kind yet brought out, and as we have had an opportunity of seeing it actually in action, we can testify that it can do all that is claimed for it. In view of the extending use of the telephone, the apparatus of Mr. Kettell is one worthy of consideration. As a rule, the number of subscribers that can safely be placed on one circuit is about eight; that is, with the mechanisms of the apparatus arranged so that the wheels, w and w_1, revolve once in a minute. Now, the angles at which the contact arms on the wheel, w, make contact with the spring, s, differ only by a few degrees in each instrument, and as it is important that the contact arms in one instrument be quite clear of the spring, s, before the corresponding arm in the next instrument makes contact in its turn with its own spring, there is a danger of the contact being made in one instrument before contact is broken in the previous one if the angles are made too small; consequently it is not advisable to have too many contacts. If the angles are increased, then the time occupied by the clock-work in passing through the whole series of contacts will be proportionally lengthened, which would cause a delay which is unadvisable. With eight subscribers the clock-work need not run longer than one-third of a minute, and it is not advisable to exceed this time, except in special cases.

If time is of no consequence, there is, of course, almost no limit to the number of subscribers that can be looped on one circuit.

In conclusion, we would state that the invention of Mr. Kettell is certainly the most satisfactory solution of the problem in question which has yet been brought out, and the fact of its being practically used, and with perfect success, is a sufficient proof of its value.

THE TELEPHONE.—We read in the *Electrician* of New York that on the evening of Friday, June 23rd, Professor Dolbear lectured on "The Developments of the Telephone" before the Electrical Society of New York. When in Europe the Professor met the assistant of Reiss, who said that, as a matter of fact, the Reiss telephone actually did transmit words and sentences.

TELEPHONES.—Under this heading the following notice has appeared in several of the Scottish daily newspapers :—

"The Bell Telephones supplied by us to various persons in

Scotland were purchased from the owners of the Bell patents, and the holders of them are requested to disregard the circulars and other communications received from the United Telephone Company (Limited), and to communicate with us—Messrs. Tasker Sons and Company, Sheffield."

THE INDUCTOPHONE.—A letter by C. O. Mailloux appears in the July number of the *Electrician* of New York on the above subject, in which the writer refers to a particular experiment made by him in July and August last, when making observations on the induction balance, which experiment led him to notice all that Mr. Willoughby Smith has recently described.

CANDLE POWER OF ELECTRIC LAMPS.—It would be well to remember in the future that the 2,000 candle power Brush lamp, as employed in the City lighting, is stated to give that amount of light when *naked*, but as covered with a globe this light is reduced 50 per cent., or to 1,000 candles. The Weston lamp, for the same purpose, is stated to give 1,600 candle power naked, and about 1,000 when enclosed, the globe only reducing the light from 30 to 40 per cent. The smaller Siemens lamps, which were stated to give 300 candle-power each, must be understood to mean when enclosed in their globes.

STREET ACCIDENT FROM ELECTRIC LIGHTING.—We notice in the *Times* of the 8th inst. and also in the Brighton papers an account of a peculiar accident which took place at the above town on the evening of the 7th inst. While the members of the local Volunteer Fire Brigade were proceeding up North Road with their fire-escape it came in contact with the electric light wire overhead, and the electric fluid descending the wirework of the escape caused those Volunteers who had control to loose their hold. Another member, thinking the machine was falling, grasped the steering rod, and received the full force of the electricity, which was so powerful as to bend him double, and disable him for upwards of an hour. We are under the impression that the system of electric lighting employed where this accident occurred is that of the "Brush."

ELECTRIC LAMPS FOR LARGE SPACES.—During the earlier stages of the City experiments with the Siemens' large lights they were kept at an altitude of 70 feet above the road and the light enclosed in a globe of clear glass. It was afterwards found that a more advantageous effect was produced by reducing the height above ground to 40 feet and employing opal globes for the lamps.

THE EDISON ELECTRIC LIGHT.—The City Engineer thus speaks of Edison's light in his report to the Commissioners of Sewers :—

"The Holborn Viaduct is at the present time lighted experimentally by the Edison Company, who have placed two incandescent lamps in each gas lantern, each lamp, as stated by the company, giving about the same light as an ordinary gas lamp, and the two, therefore, double the light of the gas lamp disused. No lamp is more than 66 feet distant from another. There is scarcely any part of the Viaduct which is better lighted than another ; there are no strong shadows to deceive the eye and the footstep ; there is no flickering and no material variation in illuminating power, so far as can be noticed by the ordinary observer, and the Viaduct is, for all practical purposes, well lighted.

"This Edison experiment will, when terminated, be specially reported on, and is only referred to here to assist in the consideration of the advantages derivable from the great volume of light given by the arc light compared with that given by the ordinary gas lighting, the incandescent lamps on the Viaduct being arranged on the same principle as the gas lighting, and aiming at uniform distribution of light over the public ways."

THE JEWS AND THE ELECTRIC LIGHT.—A singular difficulty has arisen in regard to Jewish speculation in the electric light. It is asserted that as no orthodox Hebrew will touch fire or light on the Sabbath (a circumstance not generally known), the *Jewish Chronicle* has been asked to decide whether the electric light is unlawful. The editor apparently found himself on the horns of a dilemma, for all he could say was, no orthodox Jewish minister would be prepared to answer the question. If this be so, it may well be presumed that the financial Jew will feel at liberty to use his own discretion.

THE ELECTRIC LIGHT AT LIVERPOOL.—We understand that the Pilsen and Joel Company are now placing the Pilsen arc lamp in Mr. W. Lea's music and pianoforte warehouse at Liverpool.

THE PILSEN ARC LAMP.—We understand that the Pilsen lamps recently fitted up in Messrs. Baker's premises, High Holborn, and also at Messrs. Crisps, of Holloway, are now to be seen nightly in operation.

ELECTRICAL ACCUMULATORS.—We hear that the Hammond Electric Light and Power Supply Company has acquired the right to manufacture and sell Donnithorne's accumulators for the United Kingdom, and that the "Pilsen"-"Joel" Company has also acquired the right to purchase a secondary battery patented by Woodley and Joel.

TELEGRAPHIC INTERRUPTION WITH ALEXANDRIA.—The Eastern Telegraph Company announced on Monday last that their cable ship *Chiltern* had put to sea from Alexandria to pick up the cable, and that all commercial telegrams with Alexandria were stopped. A later telegram, received by the company from their steamer *Chiltern*, stated that she was in communication with Malta and Cyprus, acting under Admiral Seymour's orders.

The Eastern Company have arranged to place a floating station off Suez to keep up communication during hostilities.

THE EASTERN TELEGRAPH COMPANY.—We observe in the *Standard* of last Wednesday the following interesting notes concerning the above company's work at Alexandria. The English public has much reason to be indebted to the Eastern Telegraph Company for the admirable manner in which, under circumstances of the greatest difficulty, the telegraphic service between Alexandria and London has been maintained. It deserves to be mentioned that the telegram which we published in our second edition yesterday morning, announcing the commencement of the bombardment, was despatched from her Majesty's ship *Invincible* at forty minutes past seven a.m., and was received in London at five minutes past six a.m. (the difference in the time between Alexandria and London being as nearly as may be two hours), so that the message reached this office within about thirty-five minutes from the time it was despatched from Alexandria. The verbal accuracy, too, with which the messages are transmitted deserves the highest praise.

At present the Eastern Telegraph Company's ship is moored about four miles from Alexandria, and has on board the cables by which she can communicate with Malta and Cyprus. The land lines in Egypt are now cut, and the Company has moored a large lighter, with their staff on board, three miles from the shore at Suez, from where they can telegraph to Aden and Bombay. Telegrams are coming from Suez round by Bombay and the Indo-European line through Persia, and going round back to the Company's floating station at Alexandria.

An interesting telephonic experiment was tried yesterday at Malta, during the bombardment of the forts at Alexandria. A telephone was attached at Malta to the Alexandria cable, and connection was made with the other end of the cable on board the *Chiltern*, off Alexandria. It was found that, owing either to the distance, or to the vibration caused by the firing, it was impracticable to send a verbal message, but the firing at Alexandria was distinctly heard, through the telephone, at Malta—a distance of more than a thousand miles.

PROTECTING THE TELEGRAPH SHIP "CHILTERN."—After the bombardment of Tuesday, Admiral Sir Beauchamp Seymour, considering the position of the *Chiltern* not altogether secure, gave orders for a vessel to cruise round her for her protection.

THE MULL TELEGRAPH CABLE.—A great deal of inconvenience having been experienced in the island of Mull, owing to the telegraph cable between the mainland and the island being broken, strong representations were made to the Postmaster-General. These representations have not been in vain, as Mr. Fawcett, replying to Lord Colin Campbell, under date July 5th, says :—"I am happy to tell you that the Department has secured the services of a ship to effect repairs to the Mull cable, and that the vessel will be despatched in a few days."

THE AMALGAMATION OF THE ENTIRE TELEGRAPHIC SYSTEM OF CANADA LEGALISED.—From the New York *Journal of the Telegraph* we observe that in the Senate of Canada, at Ottawa, on May 4th, the Act recently passed by the House of Commons legalising the amalgamation of the entire telegraphic system of the Dominion, under the charter of the Great North-Western Telegraph Company, of which Mr. Erastus Wiman, of New York, is president, was passed by a vote of 35 to 11. This consolidation was consummated some time ago, under the auspices of the Western Union Company, which by the privileges now granted to its annex, the Great North-Western Telegraph Company, has secured several substantial and important advantages. The rate in Canada for the past two years under competition has been twenty cents for ten words, irrespective of distance. But this rate has been successfully advanced 20 per cent. to twenty-five cents, and is now legalised in such a manner as to make it almost absolutely permanent. An attempt to make it otherwise, should the profits be exorbitant, was proposed in an amendment, of which the following was the concluding sentence :—"No Act of Parliament reducing the maximum rate herein provided shall be deemed an infringement of the privileges granted by this Act." This amendment was voted down by a large majority, all the members of the Government voting against it, Parliament thus practically affirming the arrangement made with the combined telegraph companies. An amendment to make the rate twenty cents for ten words received an emphatic quietus of 99 to 48, so that in every way the Commons indicated a disposition to give the contracting companies a sufficiently remunerative rate not only to do the work well but also to make some money.

NEW ATLANTIC CABLES.—We hear that the prospectuses are ready for issue of a new company, which is to lay two cables across the Atlantic. These cables are to be manufactured by the Henley's Telegraph Works Company, and when laid the contemplated tariff is to be 9d. per word.

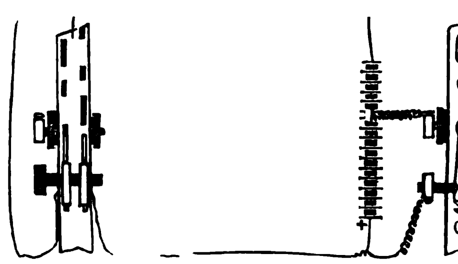
With two fresh cables by the above company, and two, as mentioned last week, to be made and put down by the India-rubber Company, tariffs between England and America should in the future rule low.

CENTRAL AND SOUTH AMERICAN TELEGRAPH COMPANY.—Panama, June 8th.—The W. T. and P. S. S. Company's steamer *Bolivar* brought a number of young men for the service of the Central and South American Telegraph Company on the coast. They are Messrs. Tracey, Pascod, Turner, Harding, Coxen, Cranwell, Rowe, Cooke, Tiddy, Davey, Hoskings, MacLachlan, Barnes, Field, Atherton, and Brain. To only a few of these have stations been assigned, and on the arrival of the *Silvertown*, which may be expected here some time in the present week, Mr. J. B. Stearns, the general manager, now on board that vessel, will arrange the distribution of those now here where the necessities of the service may require. Another contingent sailed from Liverpool by the ss. *Cuban* on the 25th ult., on the arrival of which a distribution of officers, electricians, assistants, &c., will be made from Lima to Tehuantepec. A Mr. Murphy, we are informed, will be the resident agent of the Company in this city, and to Mr. Stanley McNider, now in Guatemala, will be confided the superintendence of the line from this place to Tehuantepec. Per ss. *Dacia* and ss. *Silvertown* the following members of the Central and South American Telegraph Company's staff arrived on the coast :—Messrs. W. Kelly, J. Milne, W. Clarkson, H. F. Horan, M. Murphy, and Charles G. Murphy.

TELEGRAPH STEAMER "INTERNATIONAL."—Since the completion of the Mexican cable extension to Galveston, the ss. *International* has been chartered by the International Ocean Telegraph Company, of New York, to repair one of the Key West-Havana cables, belonging to that company. The India-Rubber, Gutta-Percha, and Telegraph Works Company received on the 4th inst. a telegram from Mr. Theophilus Smith, engineer-in-charge, announcing the safe arrival there on that day of the *International*. All well on board. The *International* will start at once, with these repairs.

AUTOMATIC TELEGRAPH.—Patent No. 259,226, filed in the United States of America Patent Office, November 8th, 1881, by Gerritt Smith :—

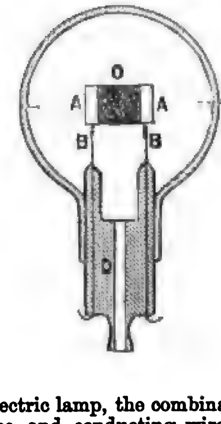
Brief.—When a perforation of the transmitting-strip is under the brush the larger battery is short-circuited, and a record is made at the receiving-station by the right-hand pen. When this short circuit is broken the larger battery overpowers the smaller, and a record is made on the other pen. Any polarised receiving-instrument may be substituted for the pen.



Claim.—The combination, substantially as hereinbefore set forth, of a pattern-strip having a single line of perforations, a circuit-closer brought into action by each perforation in said line in succession, two transmitting-batteries of unequal and contrary electromotive forces, and a receiving-instrument which responds to the action of currents of alternative polarity.

THE ELECTRIC LIGHTING BILL.—It is said that an effort will be made to carry the Electric Lighting Bill through Parliament before the adjournment.

ELECTRIC LAMP.—Patent No. 259,062, filed in the United States of America Patent Office, February 11th, 1882, by Charles J. van Depoele :—



Claim.—1. In an electric lamp, the combination with a confining-globe, a holding device, and conducting-wires, of a non-conducting medium connected with the wires, and provided upon its surface with small particles of finely-divided conducting medium secured close together, but not in electrical contact, substantially as described.

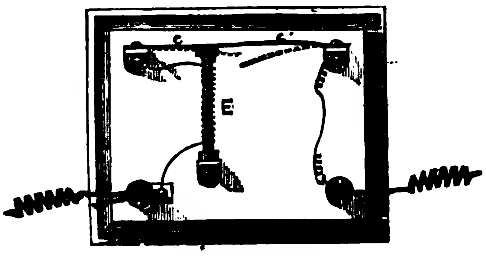
2. In an electric lamp, and in combination with the terminals, A, A, conductors, B, B, a confining globe, and a suitable support, the non-conducting medium, O, provided with small particles of carbon not in electrical contact, substantially as described.

3. In an electric lamp, the combination, with a non-conducting medium provided superficially with small particles of finely-divided conducting material not in electrical contact, of a glass globe enclosing said conducting and non-conducting mediums, and from which the air has been abstracted and replaced by some non-supporting gas, and suitable electrical connections leading from the mediums within the globe, substantially as described.

SAFETY DEVICE FOR ELECTRIC CIRCUITS. — Patent No. 259,616. Filed in the United States of America Patent Office, January 5th, 1882, by Edward Weston.

Brief.—When the paraffin, E, melts from the heat of the resistance it allows the springs, c and c', to separate and break the circuit before damage is done to the instruments in line.

Claim.—1, The combination, with an electric circuit, of a wire or similar conducting medium of higher relative resistance than the conductors with which it is connected, a circuit interrupter, and a mass of fusible material surrounded by or in proximity to the wire of high resistance, and arranged to maintain the continuity of the circuit through the interrupter until softened by heat.



2 In a safety device for electric circuits, the combination, with a circuit interrupter, of a mass of highly fusible material for preventing the same from acting, and a resistance wire included in the circuit with the interrupter, and in proximity to the fusible material, substantially as set forth.

3. In a safety device for electric circuits, the combination of springs, *c*, *c'*, a mass of fusible material for maintaining the same in contact, and a resistance wire surrounding the fusible material, for the purpose set forth.

4. The rod, E, or its equivalent, composed of a non-conducting substance, which softens at a low temperature, and powdered metal for rendering the same a better conductor of heat.

THE INSTITUTION OF CIVIL ENGINEERS.—The Council of the Institution of Civil Engineers, London, have awarded to Mr. Alan Brebner, junior, B. Sc., University of Edinburgh, the Miller Scholarship of £40 yearly for three years, for a paper on "New Forms of Dioptric Apparatus for Electric and other Flashing Lights."

NOTES ON THE LAW AND PRACTICE RELATING TO LETTERS PATENT FOR INVENTIONS.—Our readers will doubtless remember that we published a short time since in the ELECTRICAL REVIEW a series of articles on the above subject by Mr. T. J. Handford. These have now been reprinted by that gentleman with alterations and additions, and the complete pamphlet may now be obtained at his office, 42, Southampton Buildings, Chancery Lane.

ELECTRICAL PATENTS.—During the half year from July to December, 1881, 394 electrical patents were taken out in the United States of America Patent Office. Of these forty-eight are credited to T. A. Edison, and are mostly assigned to the Edison Electric Light Company of New York.

ANOTHER APPLICATION OF ELECTRICITY.—A new electrical instrument, devised by Captain M'Evoy, is likely to be of considerable value in submarine operations, such as searching for torpedoes, sunken vessels, lost anchors, &c., and it may be that submarine telegraph cable work may be aided by its employment. The invention is based on the induction balance of Professor Hughes. The instrument is so arranged that when let down by means of a cable to the bottom of the ocean, the operator, who is listening to a telephone, hears a loud noise when the case containing the apparatus is brought within the influence of the submerged metallic body.

ACCIDENT TO A TELEGRAPH LINEMAN. — A lineman named Thomas Gowrie, in the employment of the North British Railway Company, met with an accident on Saturday last, while repairing a wire at Abbeyhill Station, Edinburgh. When Gowrie was on the top of a pole it broke at the bottom, causing him to fall to the ground, whereby he sustained a fracture of the right thigh.

NEW COMPANY REGISTERED.

J. B. ROGERS ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—Capital, £510,000, divided into 100,000 A or 10 per cent. cumulative preference shares and 2,000 B or deferred shares of £5 each. Objects: To purchase the letters patent of Mr. John Banting Rogers, electrical engineer, of 47, Holborn Viaduct. The consideration is 0 cash, the 2,000 deferred shares and 12,000 prehares, such shares to be considered as fully paid up. The plant, stock-in-trade, and other business property of the vendor will be purchased by the company for £20,000. Signatories: J. T. Lovering, 77, Gresham Street, 1,000 shares; W. G. Rawlinson, 134, Cheapside, 100 shares; T. F. Brooke, 157, Richmond Road, Hackney, 20 shares; T. E. Nicholson, Highgate, 40 shares; C. W. Harris, 14, Golden Lane, 20 shares; J. J. Molyneux, Downs Park Road, Hackney, 20 shares; J. Chapman, 1, Gresham Buildings, 20 shares; B. Newstead, 100, Buckingham Road, Southgate Road, 20 shares; Henry Moore, 59, Bishopsgate Street Within, 100 shares. The signatories elect the first directors; remuneration, £2,000 per annum. Registered 5th inst. by West, King & Adams, 66, Cannon Street.

CITY NOTES.

OLD BROAD STREET.

THE EASTERN TELEGRAPH COMPANY (LIMITED).

THE report states that the company's revenue for the six months ended 31st March, 1882, amounted to £321,810 13s. 5d., from which are deducted £75,140 19s. 5d. for the ordinary expenses and £40,269 13s. 2d. for expenditure relating to repairs of cables during the half-year. After providing £2,585 1s. 4d. for income tax, there remains a balance of £203,814 19s. 6d., to which is added £29,504 9s. 6d. brought from the preceding half-year, making a total of £233,309 1s. From this amount there is deducted £22,726 9s. 2d. for interest on debentures; £20,559 1s. 3d. for dividend to 31st March, 1882, on the preference shares; and £75,000 placed to the general reserve fund; leaving a balance of £115,033 18s. 7d. The directors have, during the half-year, paid an interim dividend of 1¼ per cent. on the ordinary shares for the quarter ending December, 1881. They now recommend the declaration of a final dividend for the year ended 31st March, 1882, of 2s. 6d. per share, and a bonus of 1s. per share, both payable on the 14th instant, making, with the three previous payments on account, a total distribution for the year of 5¼ per cent. on the ordinary shares. The balance of £1,033 18s. 7d., shown at the foot of the revenue account, is proposed to be carried forward to the next half-year. The general reserve fund, after adding the interest received during the half-year, now amounts to £443,535 1s. 7d.; this, with the special reserves stated on the balance sheet, makes the total amount of reserves £490,816 14s. 6d. The revenue includes £19,500 received for the half-year upon the company's shares in the Eastern and South African Telegraph Company. The reserve funds of that company now amount to £118,695 0s. 11d., and, in addition, the sum of £37,537 10s. is held by the trustees of the sinking fund for redemption of debentures. The revenue account also includes £2,600 dividend for the half-year on the shares of the Black Sea Telegraph Company, belonging to this company, by which the line is worked and maintained under agreement.

The various sections of the company's cables are in good working order, with the exception of the direct Lisbon line and the 1870 Aden-Bombay cable. The Lisbon end of the direct cable has been recovered and buoyed, but the operations of the company's ships on the northern end of the line have been delayed owing to the continuance of very rough weather. The repairs to the Aden-Bombay cable have been deferred during the prevalence of the south-west monsoon. Owing to the disturbed state of affairs in Egypt the directors, acting in accord with Her Majesty's Government, have made arrangements to secure telegraphic communication with the fleet at Alexandria in case the connection with the shore should be interrupted. The ss. *Chiltern* has been brought from her station in the Red Sea to Alexandria, and is now there in readiness for further requirements.

A concession has been granted by the Emperor of Austria for the laying of a submarine telegraph cable between Trieste and Corfu. The cable has recently been laid by the Telegraph Construction and Maintenance Company, thus placing Austria, Hungary, and the central part of Europe in direct submarine telegraphic communication with this company's cables in the Mediterranean and Levant. The concession is exclusive for twenty years, and entitles the holders preferentially to the transmission of all official messages and to all private messages not specially directed to be sent by another route. As stated at the last ordinary general meeting, the Board have made arrangements for taking over the line and concession, and a resolution will be submitted to the extraordinary meeting empowering the directors to do so at a price not exceeding £67,000.

The directors have concluded an arrangement with the Turkish Government for the re-establishment of the connection, by telegraph cable, between Malta and the Regency of Tripoli, a distance of 220 miles. The cost will be about £25,000. A resolution will be submitted to the extraordinary meeting approving the arrangement.

On Thursday last the twentieth half-yearly general meeting of the above company was held in the City Terminus Hotel, Cannon Street, John Pender, Esq., M.P., chairman of the company, presiding. There was a large attendance of shareholders.

The Secretary, Mr. George Draper, having read the notice convening the meeting, and the minutes of last meeting having likewise been read and approved, the report was taken as read, after which,

The Chairman said that he should as usual refer to some items in the report, so that they might have a more correct idea of the working of their system during the past six months. Various items of the report were then gone over in detail. He was sorry, he said, that

during the year such a large sum had been necessarily spent for repairs to cables. That expenditure had amounted to £40,269, as against £29,942 for the previous year. He could hardly think that much exception could be taken to expenditure which was preserving their system in such a thoroughly efficient state. The increase of expenditure on salaries and wages (amounting to £5,382) had been owing to increased grants made to the principal clerks and officers of the company, in accordance with a previous resolution that so soon as the traffic reached half a million such increase would be granted. The travelling expenses had also been heavy, owing to the fact that a large number of their staff had now become entitled to leave of absence after periods of five or six years' foreign service. After commenting on other of the subordinate details, the Chairman said that having made those remarks on particular points of the report, he thought he might make a few general remarks which would be interesting to the shareholders. He continued: The first is as to the state of our cables. Well, during the last year we have had more than an ordinary amount of repairs to make, more particularly in the Bay of Biscay. We have had two steamers at work there, and it is, perhaps, the most prolonged repairs we have yet entered upon. But reading as I have, morning after morning, that the ships were obliged to run into harbour on account of the weather, I impute to the rough and continuously bad weather, the cause of the delay incurred in carrying out these repairs. We have received a communication only this morning from the captain of the *John Pender*, which is very satisfactory as far as it goes, though it would have been much more satisfactory had it announced that the cable had been repaired. However, he states that they are in harbour now through stress of weather, "but on the next occasion I propose grappling in 2,500 fathoms of water, over a splendid bottom; and, weather and sea permitting, I have every hope of being able to complete the repairs, as the cable is apparently in good condition." I may tell you that last week they had the cable on board the vessel from 2,154 fathoms of water, but the ship lurched and the cable went over. That was an accident that will occur, but it shows you, gentlemen, that we can really grapple a cable; and a thing is not lost if you know how to find it. Now, gentlemen, I hope any morning now, as we are likely to have finer weather, to hear news that the cable has been repaired. The next remark I have to make is as to the state of our cables in the Red Sea. We had two faults there in the Bombay cable. We have repaired one cable, the other fault we were going on to repair, but it so happened that at that moment the state of affairs in Egypt necessitated the bringing our steamer *Chiltern*, which generally is occupied in repairs of that nature, to Alexandria; and I think that those who are watching the state of affairs in Egypt will observe that the *Chiltern* has done a very great deal of good work (hear, hear). We may congratulate ourselves that without the *Chiltern* you would not have the same amount of news, and the Government would not have been able to guide and direct affairs as they have done, had it not been through the Eastern Telegraph system. The *Chiltern*, I may say, we have placed under the orders of Sir Beauchamp Seymour, the British Admiral, and she is now still doing good work, but I am sorry to say that the state of things in Alexandria has interrupted our system across the isthmus. Yesterday morning that interruption took place; but you need not be alarmed, because, from the foresight of your directors, we entered into a joint-purse arrangement some few years ago with the Indo-European Company that will carry us on till our connection with the East is re-established. I believe that the result of this crisis will be in all probability to give us increased security in our connection with the East. After stating that the Lipari cable was in the most satisfactory condition, Mr. Pender said: There is another point to which I desire to draw attention, that is the Trieste-Corfu cable. We have made such arrangements in connection with that cable as will be brought before you to-day by a resolution, to secure an incorporation of it with our system, which, I may say, is very important for us, looking to the great number of telegraphs which we have got in the Levant, that we should hold any new works of this kind in our own hands. At the extraordinary meeting, therefore, a resolution will be put to you —which I hope you will approve—which will enable us to secure the Trieste-Corfu Egyptian cable for ourselves. There is another concession to which I would also draw attention, and that is the Tripoli concession. That was one of the first cables laid from Malta to Tripoli, and it was laid much upon its own merits. In other words, certain traffic was likely to be secured so as to secure a fair return upon it. That cable was abandoned; it broke; and in those days the company was not rich enough to restore it. Time passed on, and I think one or two figures will justify you in thinking we are right in looking after this Tripoli-Malta concession once more. The exports in 1868 from Tripoli were £105,080; in 1878, they were £477,034; the imports in 1868 were £83,325; in 1878, £355,220. As to the shipping arrivals, in 1868 they were 262; in 1878, 858. The tonnage of arrivals in 1868 being 21,800; in 1878, 105,272. The departures in 1868 were 269; in 1878, 824, the tonnage of which was in 1868, 21,919; in 1878, 149,351 tons. Looking to this trade then, we are now likely to secure a very considerable return upon our outlay. We have been fortunate also in securing from the Porte a renewal of the concession, giving the Malta-Tripoli cable entirely into our own hands. This concession, then, is a very important one, and a resolution in regard to it will be put before you. Now, as to that very important question, the finances of the company, our debentures now are £882,000, partly in six per cents. and partly fives. We think that our property has now taken such a position in the market that we shall be able to float debenture stock at four per cent., so as to enable us to pay off the whole of our present debentures (hear, hear). A special resolution on the subject will also be brought before you, and we are going to ask you to sanction our issuing of debentures at four per cent. It is with a view to take a higher financial position, which, I think, we are fairly entitled to. We have other schemes, I may say, before us, which we may bring before you later. This only I wish you to understand, and it is a question of the progress of telegraphy. Telegraphs, I believe, must be laid to many other countries than those to which they are now laid, especially in our Indian and Colonial Empires. A demand for telegraphs will come, and I simply wish you to understand that this company will not be behind the demand when it does come. The Chairman concluded his speech by moving the adoption of the report, and recommending a declaration of a final dividend for the year ending 31st March last of 2s. 6d. per share and a bonus of 1s. per share, making a total distribution for the year of 5½ per cent. on the ordinary shares.

The Marquis of Tweeddale seconded the motion.

Mr. Stokes, after congratulating the meeting on the very favourable report which had been presented to them, and with the satisfactory progress of their business generally, asked what the Board considered a fair and reasonable sum to put to the reserve fund? It was now nearly half a million, and he would like to know to what figure they wished to carry it.

Mr. Rixon stated that he had only recently returned from the East, and he could assure the meeting that, for good order, management, and respectability, he had found no better class of men anywhere than the servants of the company there. He thought that the Board had earned the thanks both of the commercial future of the community and the public generally for the highly efficient state of their officers and staff.

Mr. Nicolson would like to know the latest information in regard to their interests in Alexandria. He believed that the position of the *Chiltern* at this crisis would show that their directors and their whole staff had had throughout only one thing in view, and that was the interests of Englishmen and of the country at large.

Mr. George Hurst said that their half million of reserve was certainly large, but at the same time he did not think it was so large as they should aim at obtaining. The security and safety of an institution like theirs required something very considerable to fall back upon. They must remember that the capital was 4½ millions, and accidents might occur which would render a large reserve fund indispensable to fall back upon. Their position at the present time was such, that under good management, like that of their existing board, their property was safe and secure as possible; their shares were almost equal to money in the funds, with the advantage of a better dividend. They should do everything in their power to strengthen their position, strong though it was, and if only in the course of a year or two they could get another half per cent. in dividend, nothing would be more satisfactory than the company's position.

Mr. Munro thought that there should be some expression on the part of the meeting of its sense of the efforts made by the staff at Alexandria during the present crisis. Some expression of that sort would encourage their *employés* in their situation in such a post of danger as many of them then occupied. Soldiers and seamen who occupied such positions were made to feel by the notice they attracted that they were really acting a patriotic part; telegraph clerks, while doing their duty in quite as efficient a manner, were perhaps less the objects of observation, and he thought some expression of the satisfaction with which this company regarded the conduct of its staff during the late crisis would be duly appreciated, and would be no more than what the Board might gracefully do (hear, hear).

Mr. Newton asked whether the report was true that one of their principal officers had been slaughtered in the atrocities of the previous day at Alexandria?

The Chairman, in replying to the various questions, said that he could not give a direct answer to Mr. Stokes's query with regard to the maximum of the reserve fund. It was most desirable, looking to their capital, which taking their ordinary shares and their debentures together, amounted to five and a half millions, that they should have a very considerably larger reserve fund than they had at the present time. They had got a very handsome sum, it was true; but when they spoke of half a million, they must speak of the five and a half millions, too, which was spread over 16,000 miles of cables. Consequently, he thought they ought to be satisfied with a comparatively moderate dividend until their reserve was very considerably augmented. It was a very handsome sum they were putting by this year—£75,000—but he had stated at former meetings that they ought to aim at a yearly addition of £100,000. Besides, in increasing their reserve fund, if they did not get their money in dividends they got it in other forms. A stable reserve fund always attracted investments, and so their shares rose in the market. When they were adding £100,000 a-year to their reserve, he should be ready then to support any gentlemen who would then propose an increased dividend for the shareholders. With regard to Mr. Rixon's remarks upon the efficiency of the staff, he believed they were thoroughly well deserved. The First Lord of the Admiralty under the last administration of this country, Mr. W. H. Smith, had told him that he never felt prouder of his country than when, on a visit to the East, he had inspected some of the Eastern Telegraph Company's stations, the tidiness, neatness, and business-like arrangements of the offices, and the smartness of the young men there employed had given him such a high impression of the quality and manner of the work done. He himself (the Chairman) had never been more pleased than when, two days ago, the present First Lord of the Admiralty, who was one of the first men of business not only in the Cabinet but in the country,—he had that old business blood of the Barings in him—had told him the pride he felt as an Englishman at reading of how the *Chiltern* had the other morning picked up a cable and re-established their connection in the short time of two hours. As to another question put, he was sorry to say that they had that morning received a telegram stating that a young fellow—a Frenchman—all honour to him for it!—had stuck to his post in their offices at Alexandria till its destruction took place, and he himself was murdered. It was a painful story to tell, but one of those incidents that all wars carried

in their train. The board would certainly recognise the extraordinary devotion which the staff generally had shown to the interests of the company during the present critical period in the East. Mr. Pender, in concluding his remarks, stated that he believed that the result of the present crisis in the East, would be to secure for England a permanent highway to her Indian and Colonial possessions; and if that were the case they would require a more widely extended system of telegraphic communication.

Mr. Newton asked whether on the Eastern Company's Telegraphic system there was at present any means of communicating between Suez and Port Said?

The Chairman replied that before long a connection between these places would be made on their system. It might have been done before this time, but Government did not always move fast, owing to the routine of a departmental system. He might remark, when speaking of the East, that the Egyptian stock, in which they had invested a good deal of their reserve fund, they had sold at 91⅞ some time ago, though he did not believe that there was any fear of that stock being permanently depreciated. Egypt, no doubt, would pay her dividends; but, as the Board looked forward, they thought they would hardly be justified in retaining the stock which they held in the face of future troubles.

After a few remarks from Lord Alfred Paget as to the efficiency of the staff, which he had observed at Chios,

The Chairman put the resolution for the adoption of the report and the declaration of the dividend to the meeting, and it was carried unanimously.

The Chairman then announced that the next resolution, which had just been drafted, was "That this meeting desires to record its thanks to the staff of the company for their services during the past year, and to declare its high appreciation of the great labour and anxiety which the company's officers have recently undergone, and of the zealous and efficient manner in which they have performed their duties under most trying and difficult circumstances."

The resolution was seconded by Mr. Munro, and carried unanimously.

The Chairman announced that that concluded the business of the ordinary meeting.

Immediately on the close of the ordinary meeting an extraordinary general meeting was held to consider resolutions sanctioning the acquisition by the company of the Trieste-Corfu Telegraph Cable and Concession, and the laying of a cable between Malta and Tripoli, and also authorising the creation and issue of mortgage debenture stock of the company to an amount not exceeding one-third of the paid-up share capital for the time being for redemption of debentures and other purposes, and regulating its transfer and the powers of the company in relation to purchasing and dealing with it.

The Chairman said that the first resolution he had to submit was that the Board be and are hereby authorised to purchase and take over the concession from the Austrian Government, dated August 19th, 1881, referred to in the directors' report, dated July 3rd, 1882, for the establishment of a submarine telegraph cable connecting Trieste and Corfu, and a cable recently laid in pursuance thereof at a total cost not exceeding £67,000.

Sir James Anderson seconded the resolution, which was carried unanimously.

The Chairman said that the next resolution was that the meeting approves of the proposal of the Board to lay a new cable between Malta and Tripoli, as mentioned in the directors' report. He might just say that they had a certain amount of spare cable which they generally kept in reserve, and that they intended to utilise for this Tripoli cable, so that the cost of the whole would be comparatively small, and at the same time they might see from the figures he had given they might expect a very considerable result from the establishment of the line of communication.

The Marquis of Tweeddale seconded the motion, which was carried unanimously.

Mr. Birt, the solicitor to the company, then read a special resolution, which was as follows:—"Resolved (A), That the board of directors be and are authorised from time to time to create and issue mortgage debenture stock of the company to an amount not exceeding one-third of the share-capital of the company for the time being, issued and paid up, upon the terms that the aggregate amount of the said stock for the time being, in issue and the interest thereon shall rank *pari passu* as a first charge on the undertaking and revenue of the company, the stock to be issued at such times and in such amounts, and on such terms and conditions as the Board may from time to time determine; for the purpose of redeeming by exchange or otherwise, the outstanding debentures of the company, and any other purpose to which the capital of this company may be lawfully applicable." "(B). That the Board be and are hereby authorised to make such provision as they may think fit for the registration and transfer of mortgage debenture stock, and for the delivery of certificates thereof, and for the issue of stock warrants to bearer, transferable by delivery, and of interest coupons attached to such certificates or warrants, or otherwise, and for the conversion of warrants to bearer into registered stock, and of registered stock into warrants to bearer, and generally as to the form and incidence of all documents relating to the said stock, so that no holding of such stock be inconsistent with paragraph A of this resolution.

"(C.) That the board be and hereby are authorised from time to time to purchase in the market, hold, and deal with, any amounts of such mortgage debenture stock for the purposes of any reserve fund or investments of the company, and with the sanction of a general meeting to apply other moneys of the company to the purchase in the market of any such stock for cancellation, and with the like sanction afterwards to re-issue mortgage debenture stock in lieu of all or any of the said stock so cancelled, provided all of the amounts of mortgage debenture stock issued and outstanding should exceed the limit prescribed in paragraph (A) of the resolutions."

The resolutions having been put by the Chairman, the Marquis of ... seconded the motion for their adoption.

Mr. Marks said that before these resolutions were carried he should like to know whether they were really necessary. He saw no advantage in issuing bonds at 4 per cent. and purchasing stock at the same rate of interest. The credit of the company was good, and he thought they could pay off these debenture bonds with surplus profits for the year. He could see no benefit at all in the proposed issue.

Mr. W. Griffiths said that the distinction between floating capital and income was so marked that, unless they had a very large income, it was a mistake to lower dividends in order to pay back a certain portion of the capital. He hoped the Board would be supported in their proposal. There was no doubt that the present state of the company was somewhat critical; and they must congratulate themselves that they had a Board which possessed so much energy, fortitude, and foresight. He was very glad indeed when he heard that they had entered into a joint-purse agreement which enabled them to carry on business in the East independent of the political crisis then existing. The resolution read by the solicitor somewhat differed from the terms laid down in the report. The report spoke merely of the debenture stock. He would make a suggestion that it would be wise in the interests of the company generally that they should not confine themselves to debenture stock, but allow any person who wanted debenture bonds to have these instead of stock.

Mr. Birt said that Mr. Griffiths might take it from him that the proposal did not apply to anything but stock and warrants to bearer.

Mr. Griffiths would still press his suggestion. He thought that an option between debenture stock and bonds would be popular with the public, and would conduce to the interest of the company.

Mr. Newton thought the shareholders ought to be congratulated on the fact that it had been determined to issue 4 per cent. stock, though it was somewhat shaking the position of those who had 5 per cent. debentures. It would shake their position, because the Board could then mortgage the property which the holders of the debentures looked to as their security. But the advantages of the issue in other ways would be so great that if it were done their telegraphic property would become a substantially secure investment to investors generally.

Mr. George Hurst would support the views of the directors on the subject. There was one great advantage in having debentures rather than fixed stock, and that was that debentures could from time to time be paid off as a company increased in prosperity; and he did trust that in the course of a few years the debenture stock would be really cleared off as well as their reserve fund greatly increased. He would not mix up the reserve fund with the debenture stock, but keep the former to relieve them in any great emergency. They could not do better than pass the resolution submitted to them.

The Chairman said that they had considered this question most carefully during the last two or three months, and they really did think that the proposed issue was the best course to adopt. If they could float that issue they would be borrowing at 4 per cent. to pay off debentures at 5.

After a few remarks from Mr. Birt in further advocacy of the proposed course, the resolutions were put to the meeting and carried unanimously.

Mr. Newton moved a vote of thanks to the chairman and the board of directors for their efficient management of the said company's affairs, and he did so, though they all knew that he had been a severe critic of the board's procedure from the very commencement of the company.

Mr. Stokes seconded the motion, which was put to the meeting and carried by acclamation.

The Chairman briefly expressed his thanks on behalf of his colleagues and himself, and the proceedings terminated.

INDIAN AND ORIENTAL ELECTRICAL STORAGE AND WORKS COMPANY (LIMITED).

A GENERAL statutory meeting of the above company was held at the Cannon Street Hotel on Tuesday, the 11th inst., Mr. Ernest N..., M.P., in the chair. The secretary, Mr. H. Cleland Heywood, having read the notice convening the meeting,

The Chairman said: Gentlemen, you are aware that by Act of Parliament a company must needs meet within three months of allotment, and therefore this statutory meeting has been called. In an ordinary way I think it is best to say next to nothing on such occasions as these. I will merely say that the allotment of the shares has been made, and we have the pleasure of telling you that all the shares were allotted, and that the applications considerably exceeded the amount registered to be allotted. But what I really wish to say to you to-day is regarding something which has happened since the allotment of shares, something that I believe will be very much to the company's advantage. You have probably heard, or may have seen it in the newspapers, that an arrangement has been made by the Electrical Power Storage Company with the Faure Company ... is concerning this that I have to say a few words. In our prospectus we put forward what we considered a very important question in buying patents—that we had a guarantee from the vendors that our patents would stand. The only real fear we had was as regards any possible infringement of our patents by the Faure accumulator, and therefore we demanded from the Storage Company, who were the vendors, that our patents should stand. We had no doubt as to the superiority of our batteries over those of the Faure accumulator, but we had a fear that those batteries—Sellon-Volckmar batteries—might possibly have some infringement. They were well advised ... there was no infringement, but still, there might be, ... made it a *sine quâ non* that we should have a guarantee ... scientific opinions we had regarding our own batteries ... satisfactory, especially that of Mr. Cromwell Varley ... well known in the electrical world, who, to use his own ... "It is a wonderful battery"; and I believe that the ... out that the Sellon-Volckmar battery is a wonderful ...

was, however, a rival in the field, that of the Faure accumulator. We had no guarantee as to that—as to our company having no rivals. All that the vendors guaranteed was that the patents were valid. Shortly after the allotment we heard that litigation was threatened between the Faure Company and the Electrical Storage Company. After a time we further heard that these two companies preferred peace to war. I am not going into the question as to the arrangement made between these two companies. That is no affair of ours; whether it was wise or unwise is no matter to us. What were the details of that arrangement is really immaterial to us. All that we need to know is that an arrangement was made between these two companies that they should work together; but there was a question which was very important to us. Did this arrangement between the two companies have any effect on our company? Now it came to pass that the Storage Company, who had guaranteed the validity of our patents, had now become the possessors of the Faure patents and the patent rights of the Faure accumulator, as regarded practically the whole world, but at all events—I only speak of the part which belongs to us—of India and the East. This being the case, we felt it incumbent upon us to enter into negotiations with what I may call the parent company. Those negotiations were chiefly carried on through Mr. Sellon, the gentleman whose name stands at the head of our patents—Sellon-Volckmar battery. I assure you that such negotiations were carried on in a manner of great fairness and uprightness. Any one who knows Mr. Sellon, knows that in dealing with him you are dealing with a man not only of remarkable cleverness, not only a great inventor, but a gentleman of remarkably upright and straightforward character, therefore in dealing with him I felt that I was secure in dealing with one who would treat this company fairly. I may say more, that though these negotiations were carried on chiefly through Mr. Sellon himself, the Electrical Storage Company met our company in an extremely honourable and more than conciliating manner. They met us in a way which I can only characterise as wishing to treat us with the favour that a father might treat his eldest son. They had taken great interest in the formation of this company, and they had a full belief in this company, as I will show you in a few moments, and therefore were determined to ascertain to a certain extent what might have been their rights, and to pass over to this company the whole of the patent rights of the Faure Accumulator Company as regards India and our other territories. The terms for which this important concession was given—and I will explain how it was an important concession in a moment—were simply these: As regards the whole amount we were to pay to the Electrical Storage Company it remained the same. The only difference which they demanded of us was a variation to the mode in which the payment was to be made. In the first place, you are aware, as you could see in our prospectus, that we were to pay £25,000 by way of royalty. This royalty might have been spread over some time, it might possibly, if we were not very successful, have been spread over some years. We have, however, now made an arrangement with them that that £25,000 for royalty should be paid within twelve months by instalments. There was another arrangement which you may recollect in our prospectus, that we were to pay £50,000 in shares, with the option of paying it in cash. Most vendors are anxious that they should be paid in cash. I have very rarely heard of a vendor company that was specially desirous of retaining the shares, or having the shares of any subsidiary company given to them, but, as I said just now, the Storage Company think well of us. I think they have reason to, but, at all events, they do think well of us, and they were desirous that they should have part of the option, as regards 5,000 of these shares, or £25,000 taken away, that we should hand over to them that £25,000 in shares without our having the option of paying them in cash. We thought that this was a very fair concession to make, and therefore as regards the option of half the shares we were to transfer to them, we have given it over to them, and they will certainly now be given 5,000 shares, and the remaining 5,000 shares will be given in shares or in cash, as we may elect. Beyond that we have paid nothing for what I shall now in a very few words try to point out are the advantages we have gained from the concessions we have obtained. I may say at once that these concessions would not have been granted to a company differently situated from ourselves. It was only in consideration of the special guarantee they had given us and the consideration that we had so early entered into the field in these negotiations that the Storage Company felt themselves justified in making such very easy terms with us in this manner. But perhaps some one will say, What is the advantage of the Faure patents to us, as you say yours are the better of the two? I do say, and I strongly affirm it, and I believe that the world will know it ere long, that the Sellon-Volckmar as secondary batteries are very much better and far stronger, and therefore are of far more commercial importance, than the Faure; but in saying that I don't want to detract for one moment from the value of the Faure accumulator; and the Faure accumulator having some advantages which the Sellon-Volckmar has not, inasmuch as the Faure accumulator is known, I may say, almost throughout the world, whereas, however much it may be known hereafter, the Sellon-Volckmar battery is at the present moment not known, though we hope it very soon will be; therefore there is that great advantage that we are now possessors of a patent so well known and so highly thought of as the Faure accumulator. There is also another great advantage, an advantage that is not to be lightly estimated by us, and that is the advantage that we get rid of what at present appears, and I believe I may say appears almost positively, the only litigation we could have entered into as regards any one attacking us. We may have eventually to enter into litigation to protect our patents from being pirated; but as regards any attack [illegible] having become the possessors of the patent rights of the [illegible]umulator we have got rid of all litigation. There is something further than that. We have also got rid in India, at all events for a time, of what would have been a rival. We have [illegible]ion of the sole accumulators that are commercially [illegible] am not prepared to say in the present state of electrical science that there may not be in the future some better mode of storing electricity than by our battery, all I can say is this, that at present there is none known, and as far as we can see there is not one likely to be discovered for some time to come that will not be an infringement of our patents. For some time, therefore, we certainly have a monopoly of what are perhaps the most important rights that there can be in the present condition of electrical knowledge. There is something else. In addition to all this, and I think this alone would show that we have obtained in these patents something of real value to our company, it enables us to manufacture our batteries at somewhat less cost. I cannot go into the details of that, and you must merely take it from me, but I have it on good authority that the manufacture of our Sellon-Volckmar batteries, which are the ones we shall continue to hold and use, may be somewhat improved, but will certainly be somewhat cheapened in the production; and that is so much clear profit to us in future. I cannot say what may be the future of electrical science, I cannot say what may be the future of either the use of electricity, or the means of storing electricity, but I can say this, and I think we may congratulate ourselves on it, that already it has been proved that the storage of electricity is a great advance in the progress of mankind in enabling us to lay hold of some of the powers of Nature, which up to this time we had not been able to lay hold of. As just one illustration I may say that we are at this moment engaged in negotiations—I may say negotiations are very nearly completed, and I trust to get a telegram very soon to say that they are completed—by which we shall be the possessors of the natural forces of a waterfall in one of our territories, and the horse-power in that waterfall will be at once transmuted into two things. One will be the lighting of a town, which will be done by a company that is ready to give us orders for batteries for that purpose, and the other will be the motive power in carrying out some important Government works in its neighbourhood. This is only just an illustration of what is in store for us. Our field is great. I believe there is no company except in our own country that will rank higher than our own as to the territories we possess. I believe there is an opening in India both for electric lighting and the use of electricity as a motive power that is not surpassed in any other country in the world.

Therefore, I think, we can look forward as perfectly knowing the difficulties we have got to encounter, difficulties from the inexperience of our electrical engineers, difficulties of all sorts that must be encountered when a new power, as it were, is brought under the dominion of man, and is being wrought as a commercial undertaking. But taking the most sober view of all these difficulties, we are quite prepared to encounter them. I think I may say with confidence that there is a very bright future for this company. There was just one point that I omitted to say anything on in speaking of the terms of becoming the possessors of the patent rights of M. Faure, and that was this—that of course the Electric Storage Company is now required to give a guarantee. We forego that guarantee then given us, because our board considers that we have really secured something far better than the guarantee, those patent rights which alone might have endangered our patents. I do not think there is any other question that I need touch upon to-day. I hope when we meet next year that I shall not have to do so—in fact I feel confident when I have the honour of addressing you then—not to speak of what we hope to do and what we may do, but of what we have done, and I think I look forward with very considerable hope to be able to say something that will be very gratifying to the shareholders of this company. I will just ask Lord Crawford, one of our directors, who is well known in the electrical and scientific world, to say a few words as regards the batteries themselves, which may be interesting to the shareholders.

Lord Crawford said: It would be very difficult to say anything on the subject of batteries without actually going into a long scientific exposition of their method of construction and use, because your chairman has already laid before you in detail the use of these batteries and the methods how they may be used. Without actually going into the practical mechanical differences between the Sellon-Volckmar and the Faure accumulator, I think, unless I were to do so, there is very little left for me to say. I am sure Mr. Noel has gone most carefully into the whole matter, and has told you exactly what is the state of the company's work. There is one thing which is practically self-evident to any one who studies electric lighting, or has anything to do with electricity, and that is the absolute necessity that there should be the means of producing electricity at a certain given time, and so putting the electricity away or storing it until such moments as you may desire to use it (hear, hear). But some means of doing this there must be. I speak not of the electric lighting of docks or of the streets, but for domestic use, or in places which could not be characterised as large places. Under such circumstances it is practically and commercially impossible to have the domestic lighting of rooms, &c., under proper control without having these storage cells whereby during the day you may put away your electricity and use it at any moment you like. I have no doubt that these storage cells, or Faure accumulator, is the only practical way of doing that. When, a few years ago, the Faure cell made a very great sensation—a sensation, I may say, throughout the world, a sensation which set busy brains at work, and clever men—Mr. Sellon produced a battery which many people say is superior to the Faure. I do not wish to go into the merits of the two, because we are practically friendly. But certainly, whether or not the Sellon is an improvement on the Faure, the Faure accumulator was the only rival that the Sellon had in the field when the arrangement was made between them. There have been batteries called storage batteries by number. You can store by decomposing water and letting it recompose itself again. You have then a force laid by, though with no great energy in it; and another thing, it is too costly to produce. The question then of these batteries, or rather, of the position of our company, is that we hold now the Sellon battery, which we may call No. 1, and we

in their train. The board would certainly recognise the extraordinary devotion which the staff generally had shown to the interests of the company during the present critical period in the East. Mr. Pender, in concluding his remarks, stated that he believed that the result of the present crisis in the East, would be to secure for England a permanent highway to her Indian and Colonial possessions; and if that were the case they would require a more widely extended system of telegraphic communication.

Mr. Newton asked whether on the Eastern Company's Telegraphic system there was at present any means of communicating between Suez and Port Said?

The Chairman replied that before long a connection between these places would be made on their system. It might have been done before this time, but Government did not always move fast, owing to the routine of a departmental system. He might remark, when speaking of the East, that the Egyptian stock, in which they had invested a good deal of their reserve fund, they had sold at 91½ some time ago, though he did not believe that there was any fear of that stock being permanently depreciated. Egypt, no doubt, would pay her dividends; but, as the Board looked forward, they thought they would hardly be justified in retaining the stock which they held in the face of future troubles.

After a few remarks from Lord Alfred Paget as to the efficiency of the staff, which he had observed at Chios,

The Chairman put the resolution for the adoption of the report and the declaration of the dividend to the meeting, and it was carried unanimously.

The Chairman then announced that the next resolution, which had just been drafted, was "That this meeting desires to record its thanks to the staff of the company for their services during the past year, and to declare its high appreciation of the great labour and anxiety which the company's officers have recently undergone, and of the zealous and efficient manner in which they have performed their duties under most trying and difficult circumstances."

The resolution was seconded by Mr. Munro, and carried unanimously.

The Chairman announced that that concluded the business of the ordinary meeting.

Immediately on the close of the ordinary meeting an extraordinary general meeting was held to consider resolutions sanctioning the acquisition by the company of the Trieste-Corfu Telegraph Cable and Concession, and the laying of a cable between Malta and Tripoli, and also authorising the creation and issue of mortgage debenture stock of the company to an amount not exceeding one-third of the paid-up share capital for the time being for redemption of debentures and other purposes, and regulating its transfer and the powers of the company in relation to purchasing and dealing with it.

The Chairman said that the first resolution he had to submit was that the Board be and are hereby authorised to purchase and take over the concession from the Austrian Government, dated August 19th, 1881, referred to in the directors' report, dated July 3rd, 1882, for the establishment of a submarine telegraph cable connecting Trieste and Corfu, and a cable recently laid in pursuance thereof at a total cost not exceeding £67,000.

Sir James Anderson seconded the resolution, which was carried unanimously.

The Chairman said that the next resolution was that the meeting approves of the proposal of the Board to lay a new cable between Malta and Tripoli, as mentioned in the directors' report. He might just say that they had a certain amount of spare cable which they generally kept in reserve, and that they intended to utilise for this Tripoli cable, so that the cost of the whole would be comparatively small, and at the same time they might see from the figures he had given they might expect a very considerable result from the establishment of the line of communication.

The Marquis of Tweeddale seconded the motion, which was carried unanimously.

Mr. Birt, the solicitor to the company, then read a special resolution, which was as follows:—"Resolved (A), That the board of directors be and are authorised from time to time to create and issue mortgage debenture stock of the company to an amount not exceeding one-third of the share-capital of the company for the time being, issued and paid up, upon the terms that the aggregate amount of the said stock for the time being, in issue and the interest thereon shall rank *pari passu* as a first charge on the undertaking and revenue of the company, the stock to be issued at such times and in such amounts, and on such terms and conditions as the Board may from time to time determine; for the purpose of redeeming by exchange or otherwise, the outstanding debentures of the company, and any other purpose to which the capital of this company may be lawfully applicable." "(B). That the Board be and are hereby authorised to make such provision as they may think fit for the registration and transfer of mortgage debenture stock, and for the delivery of certificates thereof, and for the issue of stock warrants to bearer, transferable by delivery, and of interest coupons attached to such certificates or warrants, or otherwise, and for the conversion of warrants to bearer into registered stock, and of registered stock into warrants to bearer, and generally as to the form and incidence of all documents relating to the said stock, so that no holding of such stock be inconsistent with paragraph A of this resolution.

"(C.) That the board be and hereby are authorised from time to time to purchase in the market, hold, and deal with, any amounts of such mortgage debenture stock for the purposes of any reserve fund or investments of the company, and with the sanction of a general meeting to apply other moneys of the company to the purchase in the market of any such stock for cancellation, and with the like sanction afterwards to re-issue mortgage debenture stock in lieu of all or any of the said stock so cancelled, provided all of the amounts of mortgage debenture stock issued and outstanding should never exceed the limit prescribed in paragraph (A) of the resolutions." The resolutions having been put by the Chairman, the Marquis of Tweeddale seconded the motion for their adoption.

Mr. Marks said that before these resolutions were carried he should like to know whether they were really necessary. He saw no advantage in issuing bonds at 4 per cent. and purchasing stock at the same rate of interest. The credit of the company was good, and he thought they could pay off these debenture bonds with surplus profits for the year. He could see no benefit at all in the proposed issue.

Mr. W. Griffiths said that the distinction between floating capital and income was so marked that, unless they had a very large income, it was a mistake to lower dividends in order to pay back a certain portion of the capital. He hoped the Board would be supported in their proposal. There was no doubt that the present state of the company was somewhat critical; and they must congratulate themselves that they had a Board which possessed so much energy, fortitude, and foresight. He was very glad indeed when he heard that they had entered into a joint-purse agreement which enabled them to carry on business in the East independent of the political crisis then existing. The resolution read by the solicitor somewhat differed from the terms laid down in the report. The report spoke merely of the debenture stock. He would make a suggestion that it would be wise in the interests of the company generally that they should not confine themselves to debenture stock, but allow any person who wanted debenture bonds to have these instead of stock.

Mr. Birt said that Mr. Griffiths might take it from him that the proposal did not apply to anything but stock and warrants to bearer.

Mr. Griffiths would still press his suggestion. He thought that an option between debenture stock and bonds would be popular with the public, and would conduce to the interest of the company.

Mr. Newton thought the shareholders ought to be congratulated on the fact that it had been determined to issue 4 per cent. stock, though it was somewhat shaking the position of those who had 5 per cent. debentures. It would shake their position, because the Board could then mortgage the property which the holders of these debentures looked to as their security. But the advantages of that issue in other ways would be so great that if it were done their telegraphic property would become a substantially secure investment to investors generally.

Mr. George Hurst would support the views of the directors on the subject. There was one great advantage in having debenture rather than fixed stock, and that was that debentures could from time to time be paid off as a company increased in prosperity; and he did trust that in the course of a few years the debenture stock would be really cleared off as well as their reserve fund greatly increased. He would not mix up the reserve fund with the debenture stock, but keep the former to relieve them in any great emergency. They could not do better than pass the resolution submitted to them.

The Chairman said that they had considered this question most carefully during the last two or three months, and they really did think that the proposed issue was the best course to adopt. If they could float that issue they would be borrowing at 4 per cent. to pay off debentures at 5.

After a few remarks from Mr. Birt in further advocacy of the proposed course, the resolutions were put to the meeting and carried unanimously.

Mr. Newton moved a vote of thanks to the chairman and the board of directors for their efficient management of the said company's affairs, and he did so, though they all knew that he had been a severe critic of the board's procedure from the very commencement of the company.

Mr. Stokes seconded the motion, which was put to the meeting and carried by acclamation.

The Chairman briefly expressed his thanks on behalf of his colleagues and himself, and the proceedings terminated.

INDIAN AND ORIENTAL ELECTRICAL STORAGE AND WORKS COMPANY (LIMITED).

A GENERAL statutory meeting of the above company was held at the Cannon Street Hotel on Tuesday, the 11th inst., Mr. Ernest Noel, M.P., in the chair. The secretary, Mr. H. Cleland Heywood, having read the notice convening the meeting,

The Chairman said: Gentlemen, you are aware that by Act of Parliament a company must needs meet within three months of its allotment, and therefore this statutory meeting has been called. In an ordinary way I think it is best to say next to nothing on such occasions as these. I will merely say that the allotment of the shares has been made, and we have the pleasure of telling you that all the shares were allotted, and that the applications considerably exceeded the amount registered to be allotted. But what I really wish to say to you to-day is regarding something which has happened since the allotment of shares, something that I believe will be very much to the company's advantage. You have probably heard, or may have seen it in the newspapers, that an arrangement has been made by the Electrical Power Storage Company with the Faure Company. It is concerning this that I have to say a few words. In our prospectus we put forward what we considered a very important question in buying patents—that we had a guarantee from the vendors that our patents would stand. The only real fear we had was as regards any possible infringement of our patents by the Faure accumulator, and therefore we demanded from the Storage Company, who were the vendors, that our patents should stand. We had no doubt as to the superiority of our batteries over those of the Faure accumulator, but we had a fear that those batteries—Sellon-Volckmar batteries—might possibly have some infringement. They were well advised that there was no infringement, but still, there might be, and we made it a *sine quâ non* that we should have a guarantee. The scientific opinions we had regarding our own batteries were very satisfactory, especially that of Mr. Cromwell Varley, a name well known in the electrical world, who, to use his own words, said, "It is a wonderful battery"; and I believe that the world will find out that the Sellon-Volckmar battery is a wonderful battery. There

was, however, a rival in the field, that of the Faure accumulator. We had no guarantee as to that—as to our company having no rivals. All that the vendors guaranteed was that the patents were valid. Shortly after the allotment we heard that litigation was threatened between the Faure Company and the Electrical Storage Company. After a time we further heard that these two companies preferred peace to war. I am not going into the question as to the arrangement made between these two companies. That is no affair of ours; whether it was wise or unwise is no matter to us. What were the details of that arrangement is really immaterial to us. All that we need to know is that an arrangement was made between these two companies that they should work together; but there was a question which was very important to us. Did this arrangement between the two companies have any effect on our company? Now it came to pass that the Storage Company, who had guaranteed the validity of our patents, had now become the possessors of the Faure patents and the patent rights of the Faure accumulator, as regarded practically the whole world, but at all events—I only speak of the part which belongs to us—of India and the East. This being the case, we felt it incumbent upon us to enter into negotiations with what I may call the parent company. Those negotiations were chiefly carried on through Mr. Sellon, the gentleman whose name stands at the head of our patents—Sellon-Volckmar battery. I assure you that such negotiations were carried on in a manner of great fairness and uprightness. Any one who knows Mr. Sellon, knows that in dealing with him you are dealing with a man not only of remarkable cleverness, not only a great inventor, but a gentleman of remarkably upright and straightforward character, therefore in dealing with him I felt that I was secure in dealing with one who would treat this company fairly. I may say more, that though these negotiations were carried on chiefly through Mr. Sellon himself, the Electrical Storage Company met our company in an extremely honourable and more than conciliating manner. They met us in a way which I can only characterise as wishing to treat us with the favour that a father might treat his eldest son. They had taken great interest in the formation of this company, and they had a full belief in this company, as I will show you in a few moments, and therefore were determined to ascertain to a certain extent what might have been their rights, and to pass over to this company the whole of the patent rights of the Faure Accumulator Company as regards India and our other territories. The terms for which this important concession was given—and I will explain how it was an important concession in a moment—were simply these: As regards the whole amount we were to pay to the Electrical Storage Company it remained the same. The only difference which they demanded of us was a variation to the mode in which the payment was to be made. In the first place, you are aware, as you could see in our prospectus, that we were to pay £25,000 by way of royalty. This royalty might have been spread over some time, it might possibly, if we were not very successful, have been spread over some years. We have, however, now made an arrangement with them that that £25,000 for royalty should be paid within twelve months by instalments. There was another arrangement which you may recollect in our prospectus, that we were to pay £50,000 in shares, with the option of paying it in cash. Most vendors are anxious that they should be paid in cash. I have very rarely heard of a vendor company that was specially desirous of retaining the shares, or having the shares of any subsidiary company given to them, but, as I said just now, the Storage Company think well of us. I think they have reason to, but, at all events, they do think well of us, and they were desirous that they should have part of the option, as regards 5,000 of these shares, or £25,000 taken away, that we should hand over to them that £25,000 in shares without our having the option of paying them in cash. We thought that this was a very fair concession to make, and therefore as regards the option of half the shares we were to transfer to them, we have given it over to them, and they will certainly now be given 5,000 shares, and the remaining 5,000 shares will be given in shares or in cash, as we may elect. Beyond that we have paid nothing for what I shall now in a very few words try to point out are the advantages we have gained from the concessions we have obtained. I may say at once that these concessions would not have been granted to a company differently situated from ourselves. It was only in consideration of the special guarantee they had given us and the consideration that we had so early entered into the field in these negotiations that the Storage Company felt themselves justified in making such very easy terms with us in this manner. But perhaps some one will say, What is the advantage of the Faure patents to us, as you say yours are the better of the two? I do say, and I strongly affirm it, and I believe that the world will know it ere long, that the Sellon-Volckmar as secondary batteries are very much better and far stronger, and therefore are of far more commercial importance, than the Faure; but in saying that I don't want to detract for one moment from the value of the Faure accumulator; and the Faure accumulator having some advantages which the Sellon-Volckmar has not, inasmuch as the Faure accumulator is known, I may say, almost throughout the world, whereas, however much it may be known hereafter, the Sellon-Volckmar battery is at the present moment not known, though we hope it very soon will be; therefore there is that great advantage that we are now possessors of a patent so well known and so highly thought of as the Faure accumulator. There is also another great advantage, an advantage that is not to be lightly estimated by us, and that is the advantage that we get rid of what at present appears, and I believe I may say appears almost positively, the only litigation we could have entered into as regards any one attacking us. We may have eventually to enter into litigation to prevent our patents from being pirated; but as regards any attack on us, by having become the possessors of the patent rights of the Faure accumulator we have got rid of all litigation. There is something still further than that. We have also got rid in India, at all events for a time, of what would have been a rival. We have now possession of the sole accumulators that are commercially of value. I am not prepared to say in the present state of electrical science that there may not be in the future some better mode of storing electricity than by our battery, all I can say is this, that at present there is none known, and as far as we can see there is not one likely to be discovered for some time to come that will not be an infringement of our patents. For some time, therefore, we certainly have a monopoly of what are perhaps the most important rights that there can be in the present condition of electrical knowledge. There is something else. In addition to all this, and I think this alone would show that we have obtained in these patents something of real value to our company, it enables us to manufacture our batteries at somewhat less cost. I cannot go into the details of that, and you must merely take it from me, but I have it on good authority that the manufacture of our Sellon-Volckmar batteries, which are the ones we shall continue to hold and use, may be somewhat improved, but will certainly be somewhat cheapened in the production; and that is so much clear profit to us in future. I cannot say what may be the future of electrical science, I cannot say what may be the future of either the use of electricity, or the means of storing electricity, but I can say this, and I think we may congratulate ourselves on it, that already it has been proved that the storage of electricity is a great advance in the progress of mankind in enabling us to lay hold of some of the powers of Nature, which up to this time we had not been able to lay hold of. As just one illustration I may say that we are at this moment engaged in negotiations—I may say negotiations are very nearly completed, and I trust to get a telegram very soon to say that they are completed—by which we shall be the possessors of the natural forces of a waterfall in one of our territories, and the horse-power in that waterfall will be at once transmuted into two things. One will be the lighting of a town, which will be done by a company that is ready to give us orders for batteries for that purpose, and the other will be the motive power in carrying out some important Government works in its neighbourhood. This is only just an illustration of what is in store for us. Our field is great. I believe there is no company except in our own country that will rank higher than our own as to the territories we possess. I believe there is an opening in India both for electric lighting and the use of electricity as a motive power that is not surpassed in any other country in the world.

Therefore, I think, we can look forward as perfectly knowing the difficulties we have got to encounter, difficulties from the inexperience of our electrical engineers, difficulties of all sorts that must be encountered when a new power, as it were, is brought under the dominion of man, and is being wrought as a commercial undertaking. But taking the most sober view of all these difficulties, we are quite prepared to encounter them. I think I may say with confidence that there is a very bright future for this company. There was just one point that I omitted to say anything on in speaking of the terms of becoming the possessors of the patent rights of M. Faure, and that was this—that of course the Electric Storage Company is now required to give a guarantee. We forego that guarantee then given us, because our board considers that we have really secured something far better than the guarantee, those patent rights which alone might have endangered our patents. I do not think there is any other question that I need touch upon to-day. I hope when we meet next year that I shall not have to do so—in fact I feel confident when I have the honour of addressing you then—not to speak of what we hope to do and what we may do, but of what we have done, and I think I look forward with very considerable hope to be able to say something that will be very gratifying to the shareholders of this company. I will just ask Lord Crawford, one of our directors, who is well known in the electrical and scientific world, to say a few words as regards the batteries themselves, which may be interesting to the shareholders.

Lord Crawford said: It would be very difficult to say anything on the subject of batteries without actually going into a long scientific exposition of their method of construction and use, because your chairman has already laid before you in detail the use of these batteries and the methods how they may be used. Without actually going into the practical mechanical differences between the Sellon-Volckmar and the Faure accumulator, I think, unless I were to do so, there is very little left for me to say. I am sure Mr. Noel has gone most carefully into the whole matter, and has told you exactly what is the state of the company's work. There is one thing which is practically self-evident to any one who studies electric lighting, or has anything to do with electricity, and that is the absolute necessity that there should be the means of producing electricity at a certain given time, and so putting the electricity away or storing it until such moments as you may desire to use it (hear, hear). But some means of doing this there must be. I speak not of the electric lighting of docks or of the streets, but for domestic use, or in places which could not be characterised as large places. Under such circumstances it is practically and commercially impossible to have the domestic lighting of rooms, &c., under proper control without having these storage cells whereby during the day you may put away your electricity and use it at any moment you like. I have no doubt that these storage cells, or Faure accumulator, is the only practical way of doing that. When, a few years ago, the Faure cell made a very great sensation—a sensation, I may say, throughout the world, a sensation which set busy brains at work, and clever men—Mr. Sellon produced a battery which many people say is superior to the Faure. I do not wish to go into the merits of the two, because we are practically friendly. But certainly, whether or not the Sellon is an improvement on the Faure, the Faure accumulator was the only rival that the Sellon had in the field when the arrangement was made between them. There have been batteries called storage batteries by number. You can store by decomposing water and letting it recompose itself again. You have then a force laid by, though with no great energy in it; and another thing, it is too costly to produce. The question then of these batteries, or rather, of the position of our company, is that we hold now the Sellon battery, which we may call No. 1, and we

also hold the Faure, which we may also call No. 1 with a star. I do not wish to draw any distinction between them. Especially when they are amalgamated, we have no reason to fear any danger of their being improved upon. The great difficulty of improving upon the Sellon battery is that so far as I recollect it will reproduce about 90 per cent. of the amount of energy you put into it. Giving out that amount, any person who wishes to improve upon it has only really 10 per cent. to improve upon, and that is very small indeed when you come to think of the difficulty of improving on a battery which actually does return 90 per cent. Further, I have been informed that the Sellon battery has never yet been asked to perform all that it can do. I do not think, Mr. Chairman, that I need delay the meeting any further.

The Chairman said: If any shareholder wants to ask any questions I shall be happy to answer them, though the present meeting is not like the next one, when many questions as regards our working will come up. I may say that we are commencing our work this week—at least I hope the first batteries will be delivered this week; they will certainly be tested this week, or at the beginning of next. We have purchasers for these batteries, and for as many as we are likely to obtain for the next few months. Before that time is over I have no doubt we shall have many more purchasers; and I can only anticipate that we shall not stay in want of those who so urgently demand what we have to supply. I am glad that Lord Crawford brought it out that incandescent lighting—I may be wrong, but I hold it very strongly—is simply an impossibility for domestic purposes without storage. I am connected with a company that is anxious to produce the incandescent light, and that company has stopped its incandescent lighting till it could obtain its storage batteries, because it was felt that it was unsatisfactory to have any light that you could not use just as you could use gas, as much or as little as you like, so that you have got your supply at hand, and have no fear of sudden extinction, or of the house being left in the dark by the failure of your engine or other apparatus. In fact, I think it must be self-evident to anybody who thinks of it, that storage is essential to a really effective mode of lighting our houses.

Mr. Boyd said that they had been told the effective resultant of the Sellon-Volckmar battery was 90 per cent. Could the chairman tell them what the effective strength of the Faure accumulator was?

The Chairman said he should not like to give an opinion on the Faure. Their own opinion had been that the Sellon was better, but they had not yet had the Faure batteries at work. He had often conversed with scientific men on that subject, and he himself had seen the Faure at work at Paris; but he felt that it was not just to those who thought highly of the Faure accumulator to give an opinion on the subject. He had no doubt that at their next meeting their experience would enable them to speak with some approach to certainty.

A vote of thanks to the chairman was then unanimously carried on the motion of Mr. Adamson, seconded by Mr. Kerkpatrick, and this having been briefly acknowledged, the proceedings terminated.

THE CUBA SUBMARINE TELEGRAPH COMPANY, LIMITED.

ACCORDING to the report to be presented at the meeting to be held on the 19th instant, it appears that the gross receipts for the half-year ended June 30th last, including the balance brought from last account, amount to £21,279 7s. 11d., and the gross expenditure to £5,782 9s. 11d., leaving a sum of £15,496 18s. to the credit of revenue account. Of this, the sum of £3,950 has been placed to the reserve fund, increasing that fund to £47,000. After providing for the preference dividend, a balance of £8,546 18s. remains, out of which the directors recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income-tax, which will absorb £6,400, and leave £2,146 18s. to be carried forward to the current half-year's account. The directors have pleasure in reporting that the cables have continued in good working order. In the matter of the suit instituted against the Spanish Government at Havana for a return of the tax erroneously levied on the Havana-Santiago business, which was decided by the court there in favour of the company, and the decision appealed against to Madrid, appearance has been entered on behalf of the company, and the case is now on the list of the Section of the Contencioso in the High Council of State waiting to be heard. The date of the trial has not yet, however, been fixed. At the recent extraordinary meeting to fill up the vacancy in the office of auditor, caused by the death of Mr. Cowan, several shareholders remarked upon the inconvenience of having to call a special meeting in such cases, and suggested the expediency of altering the articles of association so as to provide against similar contingencies. The directors, in order to meet these views have, with the notice of the ordinary meeting, sent out a further notice of a special resolution, which will enable the shareholders, if they think fit, after the termination of the ordinary business, to effect a slight alteration in the articles to meet the case. The director who retires from the Board at this time is Mr. Alexander F. Low, who, being eligible, offers himself for re-election. Mr. Thomas Greenwood, the auditor who was elected at the extraordinary general meeting in May, in place of the late Mr. Cowan, also retires and offers himself for re-election.

THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED).—Notice has been given, that an extraordinary general meeting of the Anglo-American Brush Electric Light Corporation (Limited) will be held at the Cannon Street Hotel, London, E.C., on Tuesday, the 18th day of July, 1882, at two o'clock in the afternoon, when the subjoined resolution will be proposed. Should such resolution be passed by the required majority it will be submitted for confirmation to a second extraordinary meeting which will be [illegible]tly convened. Proposed resolution: "That the 85th of the Association be repealed, and that in lieu thereof the following be henceforth the 85th of such articles: '85. The directors may from time to time of their own authority pay to the members in proportion to the amounts paid up, or credited as paid up, on the shares held by them respectively, such bonus and such interim dividends as in the judgment of the directors the position of the corporation justifies.'"

THE CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY.—An interim dividend has been declared, at the rate of 10 per cent. per annum for the three months ending the 30th ult.

THE TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—An interim dividend has been declared of 12s. per share to all shareholders on the register on the 10th instant.

TRAFFIC RECEIPTS.

The Cuba Submarine Telegraph Company, Limited. The number of messages passing over the lines of this company during the month of June was 3,022, estimated to produce £2,900, against 2,757 messages, producing £2,837, in the corresponding month of last year. The traffic receipts for the months of March and April estimated at £4,000 and £3,800, realised £4,123 and £3,921.

The Brazilian Submarine Telegraph Company. The traffic receipts for the week ending June 10th were £3,547, against £3,072 in the corresponding period of last year.

The Direct Spanish Telegraph Company, Limited. The estimated traffic receipts for the month of June, 1882, are £1,983, as against £1,456 in the corresponding period of last year.

The Eastern Telegraph Company. The receipts for the month of June were £46,450, against £40,074 last year.

The Eastern Extension Telegraph Company. The receipts for the month of June were £31,122, against £29,339.

Great Northern Telegraph Company. The traffic receipts in June, 1882, were £22,560 from the 1st January to 30th June, 1882, £115,560, and for corresponding months of 1881, £114,966, and 1880, £108,035.

West Coast of America Telegraph Company. The receipts for two months ending May were £6,100, against £5,050 in the same period last year.

Western and Brazilian Telegraph Company, Limited. The traffic receipts for the week ending June 16th were £1,816, against £2,066 last year. The traffic receipts for the week ending June 30th, 1882, were £1,477, both after deducting "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited.

West India and Panama Telegraph Company, Limited. The estimated receipts of this company for the half-month ended the 30th June are [illegible] as compared with £2,282 in the corresponding period of 1881.

THE TELEGRAPHIC JOURNAL AND

Electrical Review.

VOL. XI.—No. 243.

THE POSTMASTER-GENERAL AND THE TELEPHONE.

ON Monday evening in the House of Commons Mr. Fawcett, the Postmaster-General, was asked by Mr. Cross whether he had arrived at a decision as to the applications made by various companies for licences to establish and work telephonic exchanges? Mr. Fawcett's reply will be welcomed by all concerned in the future development of this partially stagnant enterprise, for he has decided to favourably entertain proposals that may be made to him by responsible persons to grant new telephone licences under certain conditions, which may be regarded as giving adequate protection to the public and the postal department. We have on many occasions felt compelled to differ from the Post-office authorities in regard to the future efficiency of the public telephonic service, notably in No. 218 of the ELECTRICAL REVIEW. It was scarcely to be expected that the Postmaster-General could long hold out against public opinion even had he been so inclined, so his conclusion that a telephonic monopoly would not be in the interests of the public is what we have all been expecting and patiently waiting for. Competition is as desirable in the case of the telephone as it is with the electric light, and as the former is doubtless destined to be of much greater service to mankind, the extraordinary activity recently shown in pushing forward our new illuminant will probably be surpassed by the interests of telephony.

The recent law-suits in Edinburgh and London have certainly done much to throw the telephonic industry open to all comers, for had it not been for the evidence there brought forth, and the unusual public interest awakened in the matter, the monopolising company might probably have held its sway for some time yet. As it is, Mr. Fawcett's decision will effect such results as he himself will eventually be gratified at seeing. The position of the telephone at present is rather peculiar, for there are doubtless many new inventions which have only been kept back by the action of the Postmaster-General, ready to compete, the moment they are set at liberty, with the only one at present in operation.

It will be remembered that in our issue of the 8th inst. we stated that we had received from reliable authority the statement that the Postmaster-General contemplated giving up the erection of private telephone wires, and that as far as telephone exchanges were concerned the Post-office authorities would not interfere as long as their own interests were not invaded. Our readers will therefore see that at least as far as half our information was involved the result has proved the correctness of our statements. The truth of the remaining part of our note is only probably a question of time. Referring to the erection of lines, Mr. Fawcett said in the House of Commons, "In case it may be supposed that inconvenience may arise from the multiplication of wires, I may remark that the licence of the Postmaster-General to establish a telephone exchange confers no special power whatever to erect poles and wires on, or to place wires under any highway or private property. The persons to whom a licence may be given will have to make their own arrangements with the local authorities and with any persons whose property may be affected. It may be well to add that the licence of the Postmaster-General confers no authority to carry on telephone business with any instrument the use of which would be an infringement of any patent." We should not imagine that telephone companies will find any insurmountable difficulties in regard to the erection of their lines on private property. Private telegraph lines have been put up in very many instances, and we do not anticipate much opposition in this respect to the introduction of the telephone. When the Telegraph Act was brought in and the Government took over the telegraphs, it was never intended that the Post-office authorities should erect private lines, and if they have done so it has been ostensibly for the convenience of their customers and not for the sake of any revenue derived from such a proceeding. It would, therefore, be advisable that the Postmaster-General should not take any further action in putting up private wires, but allow this to be performed by private companies exclusively. It is certainly unfair on the part of the postal authorities to compete in any way with private concerns, as the latter are placed at such an enormous disadvantage owing to the former having the power to put up poles and wires without obtaining the permission of those on whose property they are erected. The matter of patent rights will of course necessarily have to be settled by the competing companies, but what may be used, and what not, is now pretty generally known since Mr. Justice Fry's decision in the trial of the United Telephone Company *v.* Harrison, Cox-Walker & Co.

We said in our article bearing upon this subject, and published in the ELECTRICAL REVIEW of January 28th, that from the standpoint of efficiency to the public service we thought that competition should be allowed, an equal royalty in all cases being required. We also added that if the existing services were good, and if the desirability of intercommunication between one member of a community and any other member of that same body be so apparent, why then competition might fairly be allowed, for it could do but little harm. But if, on the other hand, the service was indifferent, wanting in energy, or the charges immoderate, then competition was the very thing to effect a cure, and therefore whichever way the question was regarded, the then action of the Postmaster-General was as unjust as it was unnecessary. The present action of Mr. Fawcett has, however, now improved the aspect of the whole matter, and the telephonic inventions which might then have been consigned to oblivion, will now have an opportunity of competing with those which have hitherto held the monopoly. When the British and Irish Telephone Company was in correspondence with the secretary of the General Post-office, one of the arguments advanced was that "this company only seeks the privilege of affording the public a far cheaper, and they hope, a better telephonic service by means of exchanges than the associated companies give, in addition to selling the best telephones for private use, which the other companies have agreed not to do."

The result of Mr. Fawcett's deliberations will be that the public will have the advantage of not merely one better system than that at present in use, but of selecting from numerous competing systems that which is best adapted from all points for the various purposes required. The United Telephone Company has never been able to instil much energy into its own movements, and the Post-office, which for awhile seemed to threaten opposition to it, fared, telephonically, still worse. It is therefore a wise proceeding on the part of Mr. Fawcett to allow new blood to come upon the scene and to carry out operations which the above named company and the Department have signally failed to achieve.

The "scientific toy" has now taken a firm stand in the necessities of our every-day life, and bids fair to be the most useful assistant we can ever expect, wherewith to carry on the commonest, or the most momentous business transactions of our daily life.

WILLOUGHBY SMITH ON INDUCTION.

IN a small pamphlet recently printed Mr. Willoughby Smith has given the results of some interesting experiments which he has recently made on "Induction." The most important of these relate to the measurement of the "specific inductive resistance" of various materials. The meaning of the term specific inductive resistance, in contradistinction to specific inductive capacity, is made clear by the following experiments of the author :—

Two equal lengths of copper wire insulated with gutta-percha were wound side by side upon a wooden reel and immersed in water. The specific inductive capacity of each length was ·084 of a microfarad. Now, to measure the "specific inductive resistance" of the dielectric, the two ends of one of the coils were connected to a galvanometer, and the other coil was then charged to the same potential as when measuring its specific inductive capacity. The deflection on the galvanometer caused by induction from the charge in the other coil was, say = 1. Two precisely similar lengths, and of the same dimensions, but insulated by a dielectric of known high specific inductive capacity, were then tested in the same way, and the following results obtained :—

Specific inductive capacity = ·288 microfarads.
Deflection on galvanometer = ·94 ,,

showing, the galvanometer deflection being less, that there was less inductive effect through the dielectric of high specific inductive capacity, or in other words that the specific inductive resistance was greater. It therefore follows (says the author), that for the dielectric of a long line of telegraph, either submarine or subterranean, where one conductor is alone employed the dielectric of the lowest specific inductive capacity is the most suitable; but where it is desirable to lessen as much as possible induction between parallel wires in close proximity, and of comparatively short lengths, then the dielectric of the highest specific inductive capacity would be the more suitable of the two.

In order to determine the specific inductive resistance of various metals, the author had the apparatus shown by the figure constructed. In this apparatus

A and B are two flat spirals fixed a suitable distance apart. In circuit with A was a battery, C, and reverser, D, and in circuit with B a similar reverser, E, and an astatic mirror reflecting galvanometer, F. The reversers were so arranged that E should reverse slightly in advance of D, and by that means a large and steady deflection was obtained, the galvanometer being always affected in the same direction by the induced currents set up in B. A plate of the substance to be tested was then placed midway between the spirals, as shown at G, and in proportion to the interception of the lines of force so were the deflections on the galvanometer; and thus, by this arrangement, very accurate and sensitive measurements could be made. By this method the following results were obtained, showing the percentage of inductive radiant energy intercepted by plates of metal sixteen inches square and half an inch thick.

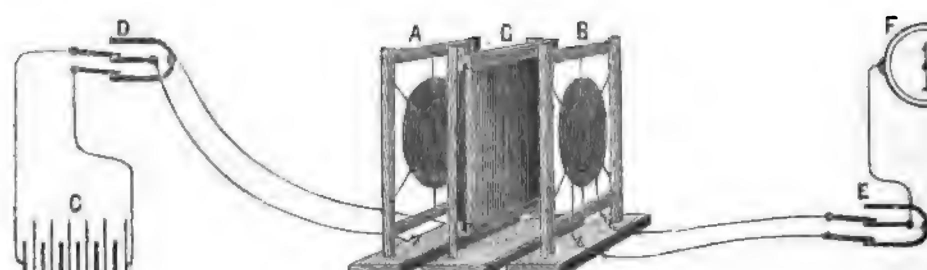

TABLE 1.

	Interception per cent.
Copper	44·1
Tin	3·5
Lead	·4
Zinc	11·9
Steel	55·3
Iron	57·0
Compressed Iron Filings	10·0

It was observed that time was an important element to be taken into account whilst testing the above metals, that is to say, the lines of force took an appreciable time to polarise the particles of the metal placed in their path, after having accomplished which they passed more freely through the same. That being so, the thought naturally occurred, *Would the results be effected by varying the speed of the reversers, so as to increase the number of the lines of force striking the plate under test in a given time?* The results given in the following table clearly show that this surmise was correct; and the knowledge gained opens out another large field for earnest thought and further investigation.

TABLE 2.

Metal under Test.	Per cent. of Inductive Energy intercepted at various speeds. Number of Reversals per Minute.							Conductivity of the Metal pure Copper = 100.
	384.	432.	504.	560.	624.	720.	Mean.	
Copper	44·1	49·6	55·2	59·4	62·1	67·5	56·3	73·0
Brass	9·3	11·3	14·7	19·9	23·9	26·5	17·6	20·4
Tin	3·5	7·4	7·4	9·7	11·3	13·1	8·7	17·4
Lead	·4	4·0	3·0	2·8	5·0	5·2	3·4	6·4
Zinc	11·9	16·1	20·2	23·6	26·0	30·9	21·4	33·3
Steel	55·3	56·8	57·6	58·0	59·0	59·8	57·7	11·7
Iron	57·0	58·1	57·8	58·4	59·8	60·0	58·5	13·8
Iron Filings	10·0	—	—	—	—	18·5	14·2	—

It will be noticed by reference to the foregoing table that the percentage of inductive energy intercepted does not increase for different speeds of the reversers, in the same ratio with different metals, the increase with iron being very slight, whilst with tin it is comparatively enormous. The following table gives the percentage of increase for each metal experimented with :—

TABLE 3.

Metal under Test.	Per cent. of Increase.
Copper	53
Brass	185
Tin	274
Lead	—
Zinc	160
Steel	8·1
Iron	5·3
Iron Filings	42·

Sheets of metal similar to those in the tables, but only 1-8th of an inch thick, in no way intercepted the lines of force.

If for each metal the mean of the results obtained with various speeds (*see* Table 2) be compared with the specific conductivity of the same, it will be seen that in each case the specific inductive resistance is in the same direction as that of their specific conductivity, with the exception of the magnetic metals iron and steel; that is to say, the higher the inductive resistance the higher the conductivity.

When two metals are combined to form an alloy, the resistance of the alloy is in most cases greater than that calculated from the resistance of the component metals and their proportions. The specific inductive resistance of alloys appears to follow in the opposite direction. For example, the percentage of inductive radiant energy intercepted by copper is 56·3, and that of zinc 21·4,

but an alloy composed of sixty parts copper and forty parts zinc only intercepted 17·6. The following will further illustrate the subject:—

Composition of Alloy.	Interception per cent.	Calculated.
67 parts Copper, 33 ,, Zinc	14·6	45·6
62 ,, Copper, 37 ,, Zinc, 1 ,, Tin	14·7	43·6

It will also be observed that the increase in the proportions of the metal copper of the highest specific inductive resistance decreases the inductive resistance of the alloy.

Dielectrics, such as gutta-percha, glass, sulphur, and shellac, as well as fluids and gases, have little or no effect in intercepting the lines of force.

The author found that when an intermittent current was sent through a spiral similar to that shown in the figure, then this intermittence was distinctly heard in an ordinary telephone held at some distance from the spiral, that is, so long as the telephone does not lie exactly in the plane of the spiral. It was found that the sounds were even heard when a copper diaphragm was used. If the coil on the magnet were short-circuited the sounds disappeared.

Referring to Table 1, the inefficiency of lead in interrupting the induction is very remarkable, and points to the inutility of employing lead-covered wires in telephone circuits for warding off inductive action between wire and wire. It is also obvious that iron forms the best protector. It would have been interesting if Mr. W. Smith had continued his experiments by making use of an earth, so as to more nearly represent the actual state of affairs in the case of telephone wires.

REVIEW.

Practical Information for Telephonists. By T. D. LOCKWOOD, Electrician, American Bell Telephone Company. New York: W. J. Johnston, 9, Murray Street.

THE position which Mr. Lockwood holds as electrician to the American Bell Telephone Company naturally gives authority to his work, and any information which it contains we may be sure will be of a thoroughly practical and useful nature. Works which pretend to be merely handbooks of the subject with which they deal are not usually considered to be of more than an instructive nature; but in the book before us Mr. Lockwood has interwoven in a most natural manner a vein of that humour which is seldom met with except in an American, and the result is that the production is both amusing and instructive, and interests while it teaches. Many of Mr. Lockwood's humorous observations are very much to the point, and contain truths which are often unheeded. We have more than once insisted upon the necessity of the apparatus used for testing purposes being not only suited for the object for which it is employed, but also upon such apparatus being handled in a manner consistent with its nature; with reference to this, we find at the conclusion of a chapter on the "Blake transmitter" the following paragraph: "Finally, my brethren, as in all electrical apparatus, when a transmitter is working well leave it alone, and never forget that when repairs or new adjustment is requisite, the instrument is not a four hundred horse-power Corliss steam engine, but a telephone transmitter."

The first chapter of Mr. Lockwood's book gives a short and well-arranged historical sketch of electricity from the earliest down to the present date. We next have "Facts and Figures about the Speaking Telephone," in which it is stated that the first record of a sound transmiting instrument in connection with which the word "Telephone" occurs, is believed to be the English patent of Sir Charles Wheatstone, No. 2462, October 10th, 1860, in which are described "Telephones in which musical pipes or free tongues are acted upon by wind." We fancy the use of the word telephone as a sound transmitter dates considerably further back than 1860. Indeed, some of our readers may remember the well-known "telephonic" concerts of Sir Charles (then Professor) Wheatstone, given at the now defunct Polytechnic Institution very many years back, in which musical sounds were transmitted a considerable distance through wooden rods. Speaking of Reiss's apparatus, Mr. Lockwood says, "that with this instrument even articulate sounds and words were transmitted, received, and understood by *those who knew beforehand what the words were going to be.* This remark seems to us a very forcible one, and considerably changes the aspect of the statement of which so much has been made, viz., that Reiss's telephone anticipated Bell's, inasmuch as it actually transmitted articulate speech. Mr. Lockwood very truly and humorously states that, "between this telephone and the speaking telephone there was a great gulf as wide as the gulf which, in the parable, separated Dives and Lazarus."

The first telephone line, it appears, was constructed early in 1877, and in May of the same year the first practical telephone exchange was operated.

The construction of telegraph or telephone lines, though dealt with in a few pages, is still dealt with in such a manner as to give a very great amount of useful practical information, small but necessary details (which are so often neglected) being given. Mr. Lockwood in giving information, goes straight to the point at once without introducing his remarks with a quantity of useless matter. All the important elements in connection with telephonic communication are dealt with in separate chapters, and while it is done in an entertaining manner, it is done thoroughly practically, thus any one reading the book carefully, ought to have no difficulty in tracing out and removing such faults as usually occur in the apparatus. The sketch of the telephone inspector as he ought to be as contrasted with what he often is, might be read with profit by many and the model copied with great advantage.

To point out the very many excellent points in Mr. Lockwood's little work (for it is but a small one), would occupy too much space, but we can heartily recommend it to all classes of readers. The only fault we can find with the book is, that it is too short and requires illustrations. We are sure that if Mr. Lockwood enlarges and illustrates his present work, he will earn the thanks of many, especially as one can see that he is a man who knows what he is writing about.

THE BAUDOT TELEGRAPH.

(*Seventh Article.*)

Relay.—It has been explained in describing the combiner that the line current does not act directly on the pointing electro-magnets. These are set in motion by a local current dependent on a relay. The relay employed by M. Baudot is shown in figs. 11 and 12; the armature is placed between two copper notches, fixed on the pole of a horse-shoe magnet. It is maintained in this position by its own weight and by the attraction of the magnet, which imparts to it its magnetism by induction. This armature moves between two coils of an ordinary electro-magnet. The magnet is placed in a wooden case, which supports two copper riders, into each of which is screwed the core of the relay coil. The play of the armature is limited by two contact studs. The relays are regulated in such a manner that when the armature is displaced under the influence of a current of a certain direction, it remains in that position until a current of the opposite direction returns it to its original position. Generally the positive current moves the armature to the *marking* contact, and the negative current moves it to the *spacing* contact. The negative current necessary to do this is supplied by a local battery, one pole of which is connected with that of the brushes of the distributor, which traverses the ring of receiving blocks. We have seen that this brush is about two contacts in advance of the brush connected to line which traverses the same crown, the blocks of which are connected to one end of the coils of the relays. Thus, at each turn of the arm of the distributor a negative current is sent into the coils of all the relays, and restores the armatures displaced at the preceding turn before the line current comes again to set them in action, according to the combination to be formed. Fig. 11 shows the perspective view of five relays;

fig. 12 gives details of the relay; the connections indicated on the diagram show how the armature of the pointing electro-magnet follows the movement of the armature of the relay. The pointing electro-magnet is an ordinary one.

Correcting Apparatus.—We are going to complete what we have merely alluded to in the description of the distributor relative to the function of the correcting sector by means of which we arrive at the synchronism of the two distributors at the home and distant stations. Let us imagine a distributor of a quadruple apparatus divided into twenty-two equal contacts; twenty will belong to the four transmitting sectors, and two will serve for correction. We will establish the connections in the manner indicated in fig. 13.

At the station, A (to the left of the diagram), the contact 21, of the second division of the sector of correction, will be connected to the positive pole of a line battery, and the contact 22, of the same division, to the negative pole of a similar battery. These same contacts on the first division being connected to the line, the positive and negative currents will be sent every time the brushes of the distributor establish communication between the two divisions. At the station, B (on the right), the contact 21, of the fourth division, will be put to earth, and the contact 22, of the same division, connected to a relay which will actuate the correcting electro-magnet (fig. 14), and displace the armature, *a*.

The displacement of the armature will raise a pin, *g*, by the movement of the arm of a lever. This pin, dropping into a hole in the distributor, will come in contact with a star-wheel, *b* (fig. 15). This wheel, *b*, has on its circumference six teeth, the intervals between which represent 1-18th of the circumference described by the arm. It is maintained in its position by a cam at the extremity of a flat spring, the other end of which is attached to the frame of the arm. By a pinion, the star-wheel gears into a second-toothed wheel, *c*, also furnished with a pinion which is in connection with the lower wheel of the vertical axle of the arm.

This wheel is put in motion by a bevel wheel fixed to one extremity of the axle of the fly-wheel, it pulls the arm which will turn regularly with it when the correcting apparatus is out of action. But at the moment when the pin, *g*, is raised, the star-wheel stopped by this obstacle will turn on itself in a direction contrary to the general movement, pulling the arm with it. The spring, drawn away during the interval between two teeth, will return of itself in the following interval; there will, therefore, be a delay in the movement of the arm determined by accessory wheels, the number of teeth in which are calculated to correspond to the value of 1-6th of the contact during 1-18th of a revolution. The return of the correcting pin is effected mechanically by means of an eccentric connected to the arm.

Regulator.—In order to correct the effect of sudden variations in the speed of the apparatus a fly-wheel is employed. This is worked by the motor by means of a crown; it constitutes, as we know, a sort of reserve force, which lessens the variations in the speed, but it does not regulate, as it does not insure isochronism.

The regulator, figs. 16, 17, and 18, is similar to that in the Hughes apparatus; it consists of a vibrating rod of steel (fig. 16), slightly tapering in form, and two metres in length. The thicker extremity, coiled into nine spirals, is firmly fixed on a support placed in the prolongation of the axle of the fly-wheel; when the rod is thus brought into an invariable position, its free end rests laterally against the back of the axle of the fly-wheel. It is connected with the movement of this axle by means of a handle consisting of several parts, the whole of which constitutes what we call the brake.

A copper arm is fixed on the back of the axle of the fly-wheel, which it accompanies in its revolutions. The free extremity of this arm is clamped to a cylindrical collet, into which is introduced, with little friction, a small pivot parallel to the axle of the fly-wheel and terminated on the side of the vibrating rod by another arm, bent at its free extremity into the form of a ring.

Into this ring is introduced the free extremity of the vibrating rod. The pivot above mentioned bears on the side of the fly-wheel an excentric cam of ivory, independent of the movement of the rod; on the point, *a*, above this cam, rests a bent spring, as is shown in fig. 17.

On the straight part of the vibrating rod is introduced a solid sphere of copper, which can be moved along the rod to bring it near to, or draw it away from, the extreme end, and thus regulate the speed.—*L'Electricien (M. Ch. Bontemps).*

M. DE MERITENS' NEW MACHINES.

[The following description of these dynamo-electric machines was written for *La Lumière Electrique* by M. Aug. Guerout.]

DURING the ten years that the ring machines have been in practical use they have been subjected to one improvement after another, and the degree of perfection to which they have now attained justifies us in asserting that the problem of transforming mechanical work into electricity is in a great measure solved.

This first and very important condition being arrived at, dynamo-electric machines still present one considerable difficulty: their price is somewhat too high for industrial applications.

This is partly due to the fact that in purchasing machines the consumer often pays for the patent rights, and partly also to a want of attention to the question of economy in the construction at first. The price being once settled and the catalogues published, scarcely any further consideration was given to the subject. But now when the patents of the principal ring machines are on the point of becoming public property, and when also a careful examination of the Pacinotti machine has proved the worthlessness of some of them, the object of constructors should be to offer their machines at the lowest possible rate, so as to bring them into general use.

Several inventors have already turned their attention to this subject; amongst others we shall speak more particularly at present of M. de Méritens, who with this object has directed all his efforts to the Pacinotti machine.

Since that time, he endeavoured firstly to render the employment of his first machine, designated by the letter C, available for public lectures.

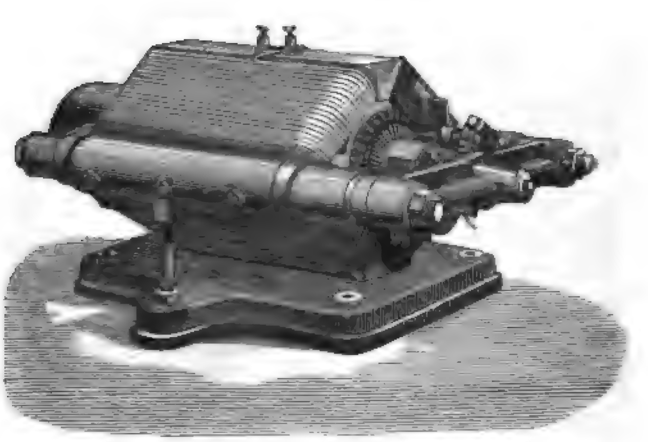

FIG. 1.

In order to do this he added to his model a system of gearing by means of which it could be worked by hand. A large toothed wheel with two handles enables four men to put the machine in motion at the speed required. If, under normal conditions, the work which one man can produce is only six kilogrammes per second, he can after an effort of a few moments arrive at a much higher result. This is why the four men working at the two handles can during a few minutes produce sufficient work to maintain by the machine an electric regulator of 100 Carcel burners. As we see, the light can only be maintained for a very short time, but this period is quite sufficient for purposes of illustration. The professors for whose benefit the apparatus was designed will certainly appreciate a model which enables them to demonstrate practically to their pupils the working of the principal

electric lamps, without resorting to motive force or using fifty battery elements. Without making any alteration in the construction of the first machine, M. de Méritens then designed a second type, designated by the letter I. It only differs from the original apparatus in that it is longer and of larger dimensions. This type has a normal speed of 2,800 revolutions, and can at high tension maintain two lights of sixty Carcel burners. (*See* fig. 2.)

turns like type I, at 2,800 revolutions, and absorbs 2½ horse-power.

The second machine, or type H, can feed a light of 650 Carcel burners with an expenditure of 4 horse-power, turning at a normal speed of 1,600 revolutions per minute. A similar machine can be used for working powerful lights, such as those used in lighthouses.

The same machine can be used to feed 25 incandescent

FIG. 2.

The cylindrical form given to the inducing electro-magnets somewhat complicated the construction of the machine. M. de Méritens thought this construction could be simplified by using flat inductors so as to give the machine the form of a straight prism with a rhombic base. The polar radiations lodging naturally in two angles of the space in which the coil is placed, there is thus no appreciable displacement. This idea suggested two types of machines, shown in figs. 1 and 3.

The first of these machines is designated by the letter J. It is of comparatively small dimensions, and constructed to maintain a light of 180 Carcel burners. It

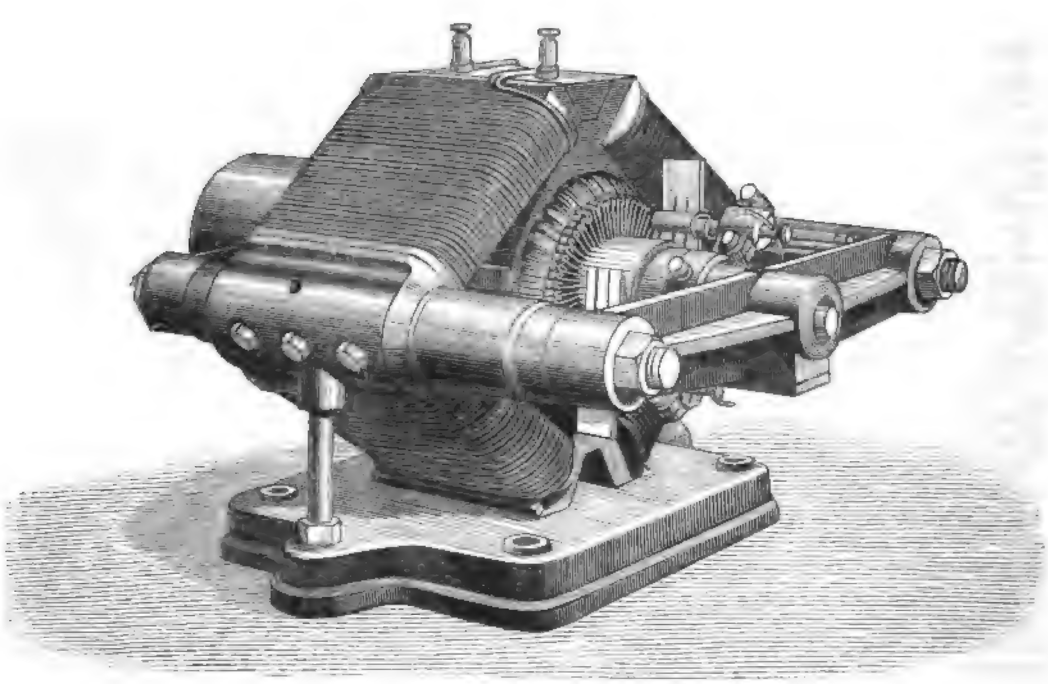

FIG. 3.

Swan lamps of two ampères each; its electromotive force is 80 volts.

The weight of these machines is reduced as far as possible. The first, type C, has been somewhat lightened, and with its present construction weighs only 30 kilogrammes. The type H, which is the most powerful, has a weight of 224 kilogrammes, and the model I weighs only 47 kilogrammes. These weights are, as we see, very moderate in proportion to the power of the machines.

Following the method indicated by M. Marcel Deprez, M. de Méritens studied these different machines, making the external resistances vary progressively.

The accompanying table gives the results obtained with the type C, the inductor and induced coil of which have each a resistance of 1·33 ohm.

Intensity in Ampères.	Electro-motive force in volts.	Resistance in ohms.	Intensity in Ampères.	Electro-motive force in volts.	Resistance in ohms.
10·69	55·05	3·49	4·50	53·95	9·33
9·66	65·11	4·08	4·14	52·04	9·91
8·97	65·66	4·66	3·96	52·07	10·49
8·28	65·41	5·24	3·70	50·08	11·08
7·59	64·44	5·83	3·45	48·40	11·66
6·90	62·58	6·41	3·17	47·26	12·25
6·55	63·21	6·99	3·11	48·17	12·83
5·86	60·0	7·58	3·10	49·82	13·41
5·35	57·88	8·16	2·80	46·62	13·99
5·0	57·0	8·74			

It must be observed that the resistances given in this table are external resistances, and that in order to obtain the total resistance, the resistance of the machine, amounting to 2·66 ohms, must be added to them.

Intensity in Ampères.	Electro-motive force in volts.	Resistance in ohms.	Intensity in Ampères.	Electro-motive force in volts.	Resistance in ohms.
1·0	15·93	15·16	15·72	57·85	2·91
1·20	17·72	14·0	20·29	62·90	2·33
1·41	19·18	12·83	22·50	63·23	2·04
1·73	21·50	11·66	26·38	66·48	1·75
2·12	23·87	10·49	27·69	65·35	1·59
3·0	30·30	9·33	29·23	64·89	1·45
4·0	35·72	8·16	31·80	65·83	1·30
5·66	43·98	7·0	35·10	67·74	1·16
7·35	48·51	5·83	37·51	67·14	1·02
9·54	51·80	4·66	51·45	69·46	0·58
13·19	56·19	3·49			

The second table gives the results of similar experiments made with the machine H, the resistance of which is 0·76. Summing up the characteristics of these machines with the help of the figures contained in the tables, we arrive at results indicating good conditions of construction. We may add that, in the types I and H the prismatic form offers great facilities of construction. The whole body of the machine may in fact be cast in two parts; the coiling of the wire is easily effected on each part, and it is then only necessary to bring them together in order to constitute the framework of the apparatus, in which we have only to adjust the induced ring.

Before concluding this article, we will indicate one more improvement effected by M. de Méritens, not in dynamo-electric machines, but in carbons for lighting. For powerful lights, such as the lamps for lighthouses, especially in the large lighthouses of England, carbons of very large diameter are used. Now it is very difficult to get these large carbons of the same composition throughout, and besides, the greater part of the time their rate of consumption is not equal. The external parts are naturally more dried up and consume quicker than the central parts. These two circumstances prevent the regular consumption of the carbons and thus affect the steadiness of the light. In order to overcome this difficulty, M. de Méritens conceived the idea of substituting for the large carbons a number of small rods of the same material, each having a diameter of three to four millimetres. These rods are connected together by fastenings of copper wire, and their number is proportionate to the thickness of the cluster employed. Each rod is covered with copper, and so is the whole cluster. In this manner the rods are well held together, and form a whole which may be considered very homogeneous on account of the very slight thickness of the layers of copper deposited by the battery.

These compound carbons give a very steady light, and we notice even that besides the regularity the light obtained is more intense than with rods in one single piece.

We can easily understand that this should be so, since every part of the cluster being consumed equally, disturbing influences are no longer produced in the central parts.

Clusters of this kind, 4 centimetres in diameter, have been tried in the large models of the English Lighthouse Administration, and have produced results in every respect satisfactory, so that the clusters will henceforward replace the old carbons

THE ELECTRIC LIGHTING BILL.

A SPECIAL sitting of the House of Commons was held on Saturday to further consider this Bill.

On the motion to go into committee upon the Bill,

Colonel Makins said that instead of waiting until the third reading before bringing on the motion standing to his name, he had decided, after consulting with the President of the Board of Trade, to mention the matter to-day; but as the forms of the House precluded him from making the motion now, he would content himself with drawing attention to the question. But although he was connected to a great extent with gas companies, he did not on this occasion represent their views. He believed gas companies generally were content with the details of this measure, and looked upon it as a strong and successful attempt to grapple with a difficult question, but they were opposed to it on two points of principle. No legislation on this matter would control or affect the competition between the various systems of electric lighting now in existence, such competition would eventually be decided by efficiency and economy alone. Gas companies were not alarmed by the progress which had been made in electric lighting in the last few years, for not only had gas the advantage of forty years' start and enormous capital, but the progress made in electric lighting was as yet more of a scientific than of a practical nature. As much, or nearly as much, capital had been subscribed towards fifty-five electric lighting companies in the last few weeks as had been expended on gas in the last forty years, namely, £13,000,000 or £14,000,000. But he was afraid that the greater portion of that sum would find its way into the pockets of experimentalists and patentees. The two points he wished the House to consider were, first, the powers taken by the Board of Trade to grant licences to companies and persons to supply electric light, and, secondly, the powers which the Bill proposed to confer on corporations to make experiments without consulting the ratepayers whose money might thus be squandered lavishly. Hitherto the power to grant licences had rested with Parliament, and it was quite a new departure for one department of the State to usurp this power. Then, under section 2 the words "public purposes" had acquired a new meaning, and would include not only streets but churches, vestry-halls, and theatres. He maintained that a theatre could not be called a public place. This power would also enable the local authorities to use the money raised by rates for supplying electric light to private consumers, and he did not think corporations had ever before possessed such a power as that without first having obtained the sources of supply. He also considered it most improper to permit local authorities to have the power of using the money of the ratepayers for what might be termed speculative purposes, more especially as there was nothing in the Bill providing for ratepayers having any control over their representatives. He would, therefore, move, "That it is undesirable to retain in the Bill the novel powers proposed to be given to the Board of Trade to grant licences to local authorities or persons enabling them to exercise powers hitherto only granted by Act of Parliament, or provisional order confirmed by Act of Parliament, and the power given to local authorities under clauses 5 and 6 and other parts of the Bill to raise money on credit of local rates without the consent of the ratepayers, for the purpose of competing with private capital, are contrary to every principle hitherto recognised by the Legislature, and that no Bill containing such powers will be acceptable to this House."

Mr. Carbutt agreed with the hon. member in condemning this new departure in legislation, which might hereafter be applied to railways and entail great loss on shareholders. It was opposed to every principle of political economy, and violated the principle of fair dealing. The public wanted electric lighting, but wished private enterprise to develop it, and then they would come in and buy up the successful undertaking the moment it paid at the price of old material. He protested against such a proposition.

Mr. Slagg argued that the value of undertakings could not be arrived at now, and wished to know why private outside companies were to be encouraged to make enormous profits out of the public without local authorities being possessed of such a power as that proposed by the Bill.

Mr. W. Fowler thought electric lighting companies ought to have at least as long a term as tramway companies, who had twenty-one years. People had gone wild about electric lighting at present, no doubt, but they subscribed their money for speculative purposes thinking they would be able to sell their shares at great profit. The Government was going too far in discouraging private enterprise.

Mr. Chamberlain said the questions raised by the hon. member for South Essex were important. The other questions could be considered in Committee. This Bill had already been exhaustively considered by the Select Committee presided over by the hon. member for Mid-Lincolnshire (Mr. Stanhope). He admitted that the power to grant licences was a new one, but it was founded on the recommendation of the Committee which sat in 1879. The object of the Government was to facilitate experiments in electric lighting, and this method was thought to be more economical than the old method of provisional order. The Board of Trade would hear evidence on both sides before granting a licence to a local authority, and then the licence would be restricted to five years. The question as to the definition of "public purposes" was of little importance. As to the question whether it was justifiable to place public money in competition with private capital without the consent of ratepayers, there were precedents for that; and he considered that corporations were degraded by so much supervision by ratepayers as that conferred by the Borough Funds Act, an Act which he hoped to see amended or repealed altogether.

Mr. Warton protested against this assumption by the Board of Trade of duties which properly belonged to other departments of the Government. It was not in any sense a scientific body, and the president merely desired to magnify his office; and that department

ought not to be allowed to trammel the progress of inventors and experimentors, who ought to be allowed to make their own way in the world as others had done before them.

Mr. MacIver said all that was wanted was that electric lighting companies should have fair play, as other companies had. He agreed with the hon. member for Bridport in protesting against the Board of Trade taking upon itself duties which ought to be left to more suitable departments.

Colonel Makins said, after the discussion which had taken place, he would withdraw his amendment.

The amendment having been accordingly withdrawn,

The House went into committee on this Bill.

Clause 1 was agreed to.

On Clause 2 being proposed,

Mr. Warton moved that music-halls should come under the definition of public places.

Mr. Chamberlain said it was immaterial whether music-halls were lighted by public or private licence.

Mr. Warton said it might become important hereafter in regard to enforcing regulations for public safety; but he would withdraw the amendment.

Mr. Carbutt moved that licences should be granted for seven years instead of five.

Mr. Chamberlain said licences were renewable with the consent of local authorities.

Sir John Lubbock asked what would be done if an agreement was made for ten years.

Mr. Chamberlain replied that a licence could only be granted for five years, but an agreement might be made with the local authority to assent to a renewal.

Mr. Serjeant Simon observed that a corporation was a perpetual body, and unless it possessed powers as strong as those to be used under the Bill, no one would enter into agreements with it.

Mr. Shaw hoped the opinion of the local public would be ascertained, as corporations did not always reflect that opinion. If the five years' limit were retained, unless the companies cared to apply for so short a licence, the Bill would probably become a dead letter.

Mr. Chamberlain explained that the Board provided for local inquiries to be held whenever they were desired. With regard to the five years' licence, it was possible to proceed by Provisional Order as well, and if the period of the licence were extended the House would lose the authority it possessed by means of provisional orders.

After some further discussion the amendment was withdrawn.

In reply to Colonel Makins the Attorney-General said there was no limit to the renewals of licences.

Colonel Makins entered a protest against the system of licences, believing they would work injuriously to public interests.

Clause 2 was agreed to.

Clauses 3 and 4 were also agreed to, but on clause 5

Mr. Pugh moved an amendment preventing local authorities incurring the expense of carrying out a scheme for electric lighting, without first obtaining the consent of the ratepayers.

Colonel Makins supported the amendment, but thought its object might be attained by making a preliminary inquiry compulsory.

Mr. Chamberlain said the best security for the honesty of the local authorities was in making them thoroughly responsible, and not in keeping them in leading strings. A local inquiry must take place before a corporation could borrow money, and the Board of Trade would encourage such inquiries.

The amendment was eventually withdrawn and clause 5 was agreed to.

Clauses 6 to 13 having been agreed to,

On clause 14, provision for the protection of the Postmaster-General, and for the purchase of undertakings by local authorities,

Mr. W. N. Nicholson moved an amendment extending the time after which a local authority might require persons who supply electric light within its jurisdiction to sell their undertaking from 15 to 21 years.

Mr. Chamberlain said the period of 15 years was a compromise fixed upon by the select committee between the two periods which had been suggested, and they were of opinion that that time would be sufficient for experiments to be made. The committee had two objects in view: first, not to throw obstructions in the way of companies; and, secondly, to protect the interests of the public from suffering from such monopolies as gas and water companies had obtained. He believed all the electric companies, with the exception of the Edison Company, had expressed their satisfaction at the period fixed. He was of opinion that the time given should be long enough to enable the companies to make satisfactory experiments.

Mr. Carbutt supported the proposal.

Mr. Slagg and Mr. J. Jenkins thought fifteen years sufficient.

Mr. Story-Maskelyne said several companies had informed him that they were satisfied with fifteen years, and—

Mr. W. N. Nicholson withdrew the amendment, being satisfied with assurances that the companies generally were satisfied with the time fixed.

Mr. J. K. Cross moved to introduce the following words in the purchase clause: "With such addition for goodwill as may be agreed upon, or, failing agreement, as may be determined by arbitration, but without any addition for compulsory purchase; and, provided always, that the sum paid shall not exceed by more than 25 per cent. the value ascertained as aforesaid. When a part only of the undertaking is purchased, payment shall be made on the same terms, but with such addition as may be requisite to compensate for loss occasioned by severance."

Mr. Rathbone opposed the amendment, believing that it was antagonistic to the public interest.

Sir John Lubbock asked the President of the Board of Trade to explain the clause.

Mr. Chamberlain said this clause had been drawn up with the intention of insuring that the purchasers should pay the same price as if they bought in the open market. If the local authorities were debarred from purchasing the undertaking at the end of a reasonable term at a reasonable price, they would only have the alternative of setting up in business for themselves; therefore he thought the amendment was against the companies.

Mr. Cross withdrew his amendment.

Clauses 14, 15, 16, 17, 18 and 19 were then added to the Bill.

On clause 20,

Mr. J. Hamilton moved that so far as Ireland was concerned the Local Government Board should be substituted for the Board of Trade.

Mr. Chamberlain said he was willing to take the opinion of Irish members on this point, although he thought it would be better that the management should all be in the hands of one body.

Mr. Stanhope advised that the control for England, Scotland and Ireland should be in the same hands.

The amendment was, however, withdrawn and clause 20 agreed to.

Mr. Barran next moved the following new clause:—"No application for a provisional order on the part of any company or person shall be made in respect of all or any part of the district of a municipal, or other local authority, without six months' notice in writing (which shall define the area intended to be comprised therein) to such authority, who shall, within that period, be entitled to make application for a provisional order in respect of all or any (including the area defined in such notice) of such district; and until such application has been disposed of no other application shall be entertained."

The Hon. Member hoped the committee would see how necessary it was that the supply of electric light should be controlled by the local authorities. In the case of the gas supply to Leeds, the difference between the cost of gas when in the hands of private companies and the corporation was remarkably significant. The companies, which were bought up by the corporation for £800,000 or £900,000, charged from 3s. 6d. to 4s. 6d. per 1,000 cubic feet, but the corporation supplied gas to the city and some outlying districts at 1s. 10d. per 1,000 cubic feet.

Mr. Chamberlain agreed with the principle of the proposed clause, but thought it was not necessary as the Bill contained similar provisions. He could not accept the clause.

Mr. Stanhope said the select committe had discussed the question of notice very exhaustively, and had come to the conclusion that three months were quite long enough for a corporation to make up its mind, and therefore he hoped the new clause would not be accepted.

The committee divided, with the following result:—

For the clause	29
Against	88
Majority ...	59

The clause was rejected, and the schedule having been agreed to, the bill was reported.

CORRESPONDENCE.

TO CORRESPONDENTS.

Correspondence should arrive not later than Tuesday morning if it is desired to appear in the following number.

FIRE RISKS FROM ELECTRIC LIGHTING.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Sparks falling from the carbons of an arc lamp are no doubt a source of danger; and the fire insurance offices, in the exercise of their duty, are quite right to turn their serious attention to the subject. There are other fire risks attending the careless use of the electric light of which cognisance must also be taken; but one fails to see the relevancy of a great deal of the gratuitous advice contained in the somewhat fussy "Rules and regulations for the prevention of fire risks arising from electric lighting," which the Council of the Society of Telegraph Engineers and of Electricians have been pleased to issue.

Their first "rule" for the prevention of fire risks is that "the dynamo machine should be fixed in a dry place;" scarcely, it is to be apprehended, because if fixed in a wet place it would be likely to set the wet on fire. But the Council have no doubt their good reasons for considering that fire risk would be increased by dampness of the machine, although they don't state why.

"It should not be exposed to dust or flyings" (whatever the latter may be), is rule 2; and if the nature of dust and "flyings" is to be explosive or combustible, the Council are right in mentioning them as amongst the fire risks. Much the same may be said of many of the other rules.

In the middle of the rules and regulations the Council

strongly urge—in three separate paragraphs, one beginning with N.B.—"the employment of safety fuses;" but they do not mention the name of the patentee, nor give his address, in case one may have occasion to communicate with him. One concludes, therefore, that he must be the man in the moon, whose name does not appear on the committee, but who has probably mentally influenced these rules, regulations, and N.B.'s. As I understand the description of these fuses, which "are of the very essence of safety" [beware of fraudulent imitations!], they amount to no more than the old French lightning guard of Breguet, in which a fine iron wire was fused when too much (atmospheric) electricity happened to go through it. But the safety fuse, which is "of the very essence of safety," recommended by the Council, is "constructed of easily fusible metal, which would be melted if the current attain any undue magnitude, and would thus cause the circuit to be broken," and, I conclude, put all the lights out. I cannot help thinking that this fuse, which may be "of the very essence of safety," is not of the very essence of originality, and one cannot be sure whether the united genius of the eighteen gentlemen who are responsible for this indirect, and perhaps unconscious, advertisement, might not be able to suggest something much more refined. But the matter is at least relevant to the subject of fire risks, which is more than can honestly be said for a good many of the rules.

A second N.B. (which by the way has no connection whatever with the rule which precedes it), recommends the frequent testing of the wires. We are told: "It is an operation, skill in which is easily acquired and applied,"—particularly when using certain testing apparatus, invented probably, by the man in the moon; but this is not specified.

The Council then proceed to give a rule and regulation that "the escape of electricity cannot be "detected by the sense of smell," after which effort of originality, we are comforted by the assurance that "it can be detected by apparatus far more certain and delicate;" and it might have been added to this—"portable and guaranteed to be of the best workmanship, and the invention of the man in the moon."

The final rules for the prevention of fire risks are to the effect that wires should be arranged so that no one can be exposed to the shocks of alternate currents exceeding 60 volts, but it is not stated whether this is for fear of the individual being set on fire; and that if the difference of potential within any house exceed (the Council say exceeds) 200 volts the *outside* of the house should be provided with a switch, so arranged that the supply of electricity can be at once cut off—probably in the event of a passing policeman seeing any of the inmates in a state of incandescence at the windows.

It is, at first sight, not quite clear where the Council obtained such exact information regarding the danger point—viz., 60 volts—of alternate current circuits (though why 60 volts in particular rather than 50 or 70, most of us are as ignorant as probably the Council themselves), while they do not say anything about the much higher potential differences found in some of the continuous current systems. It would not be an incorrect statement that the majority of instances in which death has resulted from incautiously touching wires, has been in connection with systems employing continuous currents. Surely the man in the moon cannot have invented a continuous current machine!

In all systems, care has to be taken to keep out of danger, and people will learn to avoid new dangers just as they have learnt to avoid old ones, such as keeping gas streaming into a room for an hour or so before lighting it; or to avoid taking hold with the naked hand of the business-end of a red-hot poker.

The intention of these rules is admirable, but it is doubtful whether the rules themselves are quite up to what we would have expected. There is a strong suspicion of oblique puff in some of the paragraphs, and these are served up amongst a good deal of very common knowledge, and a little grand-motherly twaddle, all which could have been done just as well without the imposing array of eighteen scientific gentlemen, one half at least of whom have had no practical experience whatever in connection with the subject upon which they undertook to legislate. Truly in this case, as in that of the lightning-rod committee, the mountain in labour has brought forth a mouse. Seeing that this effort of intellect has been issued gratis, unlike the report of the lightning-rod committee, which cost 5s., it may be thought, perhaps, a little ungracious not to pass it over in silence; but when the council of an important scientific society, with high aims and serious work before them, go out of their way to prove over again the truth of the old saying, that gratuitous advice is worth just what it costs, one cannot help regretting that their efforts were not devoted to a more useful purpose.

Faithfully yours,
C. E.

THE CRYSTAL PALACE ELECTRICAL EXHIBITION.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Will you kindly inform me, through your columns, when the Honorary Council of Advice of the late International Electric Exhibition held at the Crystal Palace are likely to make known the jurors' awards to the exhibitors of the same, as I am informed that the second exhibition of electric appliances will shortly take place, and the forms applying for space should be filled in and returned before August 1st next?

As an exhibitor in the last exhibition I do not feel justified in making application for space until I know the result arrived at by them—whether it be satisfactory to the general body of the exhibitors or not, and in that interest I shall be glad to know the result.

I am, Sirs, yours truly,

July 18th, 1882. DISQUE.

THE TELEPHONE.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—The documents sent you by Mr. Silvanus Thompson, in his letter of the 1st instant, relating to the results obtained by Reiss, are evidently interesting, and I shall endeavour to reproduce them in the next edition of my work on the telephone; but they will scarcely alter my ideas as to the share to be ascribed to Mr. Reiss in the discovery of the *speaking* telephone, for if he did effect the reproduction of speech, he only did so, in my opinion, accidentally, for nowhere does he mention the grand principle of the intervention of undulatory currents, which alone could lead to this remarkable result. For sounds to be reproduced by a receiver consisting of *an iron wire enclosed in a helix and stretched on a sounding case placed on a table* (the only Reiss receiver known), the currents sent by his transmitter must have been *interrupted*, and hence the reproduction of articulate speech *could only have been effected accidentally* when the two contacts were by chance maintained one against the other; and as this contact, when prolonged, would stop the sounds on account of the limited extent of the variations in intensity of the currents with such contacts, only irregular and discontinuous effects could be obtained. If the telephonic receiver had been adapted to be held at the ear speech might have been heard in a more continuous manner; but I have never heard of a Reiss receiver so constructed. However, according to Prof. Dolbear, Reiss had constructed a model with an electro-magnet and an armature. Was it with this receiver that the effects quoted by Mr. Thompson were obtained?

However this may be, it seems probable that if Mr. Reiss had really penetrated the principle of the articulating telephone he would have substituted for the metallic contacts some of moderate conductivity, so as to obtain a greater extent for the variations in intensity of the currents transmitted, and he would, besides, have arranged his telephone to be applied to the ear, if his principal object had not been to reproduce musical sound sufficiently loudly to be heard at a distance, and by several persons at once. The prospectus of which Mr. Thompson speaks proves nothing, for it is very certain that if the problem of *seeing to a distance* is one day solved, it cannot be said that it was effected two years ago, as the American newspapers said that *a means had been discovered of seeing by telegraph*. At this rate it might also be said that Manzetti, of Aosta, also discovered the telephone, for in 1865 a number of journals announced that he had found out a means of transmitting speech.

It is probable that in this matter, as in the greater number of modern inventions, the original inventor obtained only insignificant results, and that it was the man who first succeeded in arranging his apparatus so as to obtain really striking results that received the honour of the discovery, and rendered it popular. Nevertheless, it would not be just not to acknowledge that the Reiss telephone *formed the starting-point of all the others*; and that is what I have said and repeated in all my writings. Mr. Bell himself owned it in his paper, which was read at the Society of Telegraphic Engineers in London. As a last argument I will say that if the transmission of speech had been obtained by Mr. Reiss in 1863, as Mr. Thompson asserts, the discovery would have attracted as much attention at that time as when it was announced to us from America in 1876. I now come to Mr. Henry C. Buck's letter inserted in the ELECTRICAL REVIEW for the 15th inst. It is said there that Professor Dolbear had invented his telephonic system before the date which I have fixed for the researches of M. Herz. If this be so, how is it that the system, the excellent effects obtained from which I observed myself at last year's exhibition, was not made public before the middle of the year 1881? Mr. Buck will admit that a writer can only speak of inventions that have become public, and he will also acknowledge that as regards this question of priority we can only depend on the dates of patents or of publications appearing at certain periods. Now, the American journals, at any rate those we have received in France, did not begin to speak of Professor Dolbear's telephone with condenser until the middle of 1881, and even after having described M. Dunand's system. Mr. Buck, in his letter, does not touch upon the date of Professor Dolbear's first researches. It seems to me, however, that instruments of such importance deserved to occupy the attention of scientific journals as soon as they were constructed. All that I can say is that the patent of Dr. Herz dates from the beginning of June, 1880. I will also say to Mr. Buck, as well as to Mr. S. Thompson, that, being in no way interested in this question of invention, I wish to write in the interests of truth alone, and that when my assertions are *proved* to me to be incorrect I am quite ready to rectify them.

TH. DU MONCEL.

Lebisey, *July 17th*, 1882.

NOTES.

SCIENTIFIC REPORTS ON ELECTRIC LIGHTS.—We extract the following from the advertisements of J. B. Rogers' Electric Light and Power Company. It is from the report of J. E. H. Gordon, Esq., B.A., M.S.T.E. :—

Having been requested by the directors to examine Mr. Rogers' Electric Incandescent Lamps, I visited his show rooms, 47, Holborn Viaduct, on the evening of June 1st, 1882.

As a preliminary step to the determination of the efficiency, I took a lamp at random from the electrolier and had it moved into a dark passage behind the show room, where I determined its candle-power. I found it to be 34 candles.

On June 2nd, 20 lamps, including the one whose candle-power I had taken, were sent to me to experiment on. The result of a number of experiments showed that when worked to 34 candles, the lamps had an efficiency of 242 candles per electric horse-power.

This is an extremely high efficiency, being sensibly equal to that of the Swan lamps, and much superior to that of Edison's.

In order to test the strength and probable durability of the lamps, I worked some of them with powerful currents at temperature and candle-power much above those at which they are intended to be used.

I worked one of the 34-candle lamps to a light of 140 candles, when the efficiency was no less than 536 candles per electric horse-power. The lamp stood this enormous temperature for $5\frac{1}{2}$ minutes before the filament broke. I consider this a very severe test of the strength of the filament, and the result an eminently satisfactory one.

To sum up, I can speak in high terms of the lamps constructed by Mr. Rogers.

We are astonished that men of high scientific standing should allow themselves to pose as authorities on electric lighting without first being sure that their statements are correct.

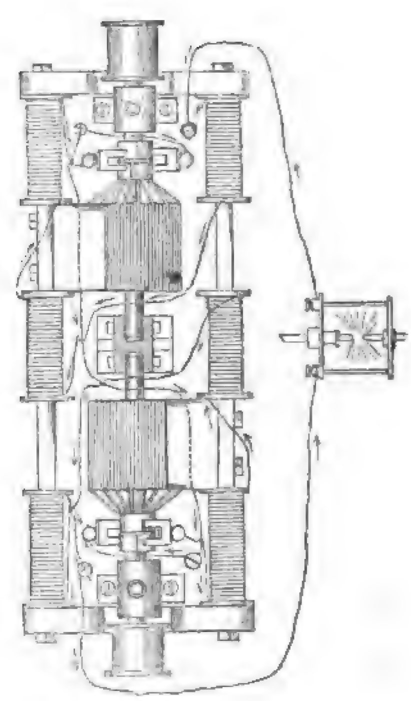
Taking Mr. Gordon's first assertion that the Rogers lamp when worked at 34 candles gives an efficiency of 242 candles per electric horse-power, this result is said to be sensibly equal to Swan's, and much superior to that of Edison's.

We beg to call Mr. Gordon's attention to the paper by W. Crookes, F.R.S., reporting on the incandescent lamps at the late Electrical Exhibition in Paris, and published in full in our issue of June 17th. When the Edison lamps were worked at 32 candle-power (two less than that of Rogers', be it noted), the efficiency per horse-power averaged 300 candles. Therefore even nine months ago the Edison lamps showed a higher value than the present Rogers lamp by nearly 20 per cent. In regard to the second experiment of Mr. Gordon, which is useless and misleading, we need only mention that months ago single Maxim lamps were tested by Professors Ayrton and Perry from their normal candle-power to 1,000 or more, and that the efficiency per electrical horse-power rose to 1,100.

We can only express our regret that Mr. Gordon should lend his name to any company without satisfying himself as to what has been published before concerning the value of the incandescent lamps at present in use. As the public must necessarily depend upon scientific authority for basing their decisions before investing, it would be well if experts dropped the misleading and utterly valueless methods generally adopted in wording their reports.

DYNAMO-ELECTRIC MACHINE.—Patent No. 259,791, filed in the United States of America Patent Office November 21st, 1881, by Charles E. Ball :—

Brief.—The armatures are revolved before one pole only of the field-magnet. Two armatures are mounted on independent shafts and connected in series with each other and the field-magnet coils, each armature rotating before one pole of the field-magnet.



Claim.—1. In a dynamo-electric machine, a single electro-magnet and an armature located and adapted to rotate within the inductive field of only one of the poles of such magnet, substantially as set forth.

2. In a dynamo-electric machine, the combination of two armatures and an electro-magnet or magnets, each of said armatures being arranged and adapted to rotate in the inductive field of only a single pole of such magnet or magnets, substantially as set forth.

3. In a dynamo-electric machine, the combination of two armatures and two poles of an electro-magnet or magnets, each of said armatures rotating in the inductive field of only a single pole, and said armatures and magnet or magnets being in the same circuit, substantially as set forth.

4. In a dynamo-electric machine, the combination of two armatures on independent shafts, whereby they may be rotated in opposite directions, and an electro-magnet or magnets in circuit therewith, each of said armatures being located and adapted to be rotated within the inductive field of only one pole of a magnet, substantially as set forth.

5. In a dynamo-electric machine, the combination of two armatures and an electro-magnet or magnets having pole-pieces on opposite sides of the machines, said armatures and magnet or magnets being relatively arranged substantially as described, whereby each of said armatures is located and adapted to be rotated within the inductive field of only one magnetic pole, substantially as set forth.

6. The combination, in a dynamo-electric machine, of two arma-

tures and an electro-magnet or magnets having pole-pieces on opposite sides, each of said armatures being located and adapted to rotate in the inductive field of only one pole of a magnet, said armatures and electro-magnets being connected substantially as described, whereby the circuit is direct from one armature to the other, and through all the helices of the magnets successively, substantially as shown and described.

7. The combination of two armatures on independent shafts, and an electro-magnet or magnets having pole-pieces on opposite sides of said armatures, the latter being located and adapted to rotate each within the inductive field of only one magnetic pole, said armature and magnet or magnets being in the same circuits, substantially as set forth.

The Maxim-Weston Company's Arc Lamp.—The chairman of the Maxim-Weston Company, in order to show the superiority of the Company's system, gave an extract from a paper by Mr. Sang, read before the Gas Institute in June last. The following comparison of lights was made: Duplex system light, 114 candles; Brush, 557; Maxim-Weston, 1,406. As there is no mention of horse-power used in producing these results they may be put in the category of "Half truths and whole truths." Colonel Gilbey, in the course of his remarks, said he believed that wherever the Company's lights were shown they extinguished everything else. Leaving these egotistical remarks for the shareholders of the Company to pride themselves on, we do believe that it was a wise proceeding on the part of the directors to attach a new name to the Company, and we shall therefore be glad to see it prosper under new auspices.

The Lighting of Public Thoroughfares.—The Engineer to the Commissioners of Sewers says:—"For public thoroughfares, uniform distribution of light, generally speaking, best meets the public requirements, and this can be most successfully obtained by many small lights at small distances apart. Powerful centres of light at long intervals apart give intense brightness with deep shadows in their immediate vicinity, and distribute the light very unequally over the areas assigned to them; tested by this principle the excess of light given by the electric lamps was much less valuable than might be supposed."

Electric Domestic Lighting.—If the electric light is ever to become popular it must, the *Building and Engineering Times* says, be adapted to the indoor and everyday needs of the mercantile community especially, to the wants of the home, and it must also be brought within the bounds of financial economy. To achieve these ends a fair opportunity offers in the City of London, where several of the leading electric light companies are now working their systems in competition with each other alike in point of excellence and of cost, and the opportunity thus afforded is made all the more valuable by the fact that a large body of the shopkeepers and merchants along the various routes are willing and anxious to have the new illuminant applied to their premises, and have memorialised the City Commission of Sewers to that effect. It has been one of the salient statements of the electric light companies that they could split up their supply into sufficient detail to furnish illumination for domestic lighting; they apparently longed for the opportunity of doing so, and they have on many occasions made attempts at this with isolated shops or warehouses. But the circumstances indicated above are such as have hitherto given no opportunity in London for the companies to show us what they can do efficiently and cheaply, and it is therefore a pity that delays and complications should be imported, as they have been, by the Commissioners, who elected that the petition from the merchants and traders should be referred back for further consideration. What we want is light; literally as regards illumination, and figuratively as to the capabilities of the companies, and it is a pity that obstructions should be created in any quarter.

Fire Risks from Electric Lighting.—The following form has been adopted by the fire underwriters of Baltimore, Md., to be placed upon policies when electric lights are introduced into premises: "Privilege granted to use the electric light in the within-mentioned premises, provided the assured holds a certificate and guarantee from the company wishing the light that the equipment is and shall be maintained according to the standard of the New York Board of Fire Underwriters."—*The New York Electrician.*

Edison's Electric Light.—We read in *La Lumière Electrique* that the Edison Electric Lighting Company is now making the necessary preparations to put up lamps of their system in Paris.

Up to the present they have only occupied themselves with orders for the fitting of their lamps received from different towns in Europe, among others, Amsterdam, Antwerp, Brussels, Berlin, Frankfort, Sarreguemines, Brünn in Moravia, Steier, Vienna, Milan, and Bologna. In the first of these towns a central station is now being established, intended to feed 2,000 lamps distributed in different parts of the town. In Antwerp, a sugar refinery is lighted by 200 lamps of this system. In Brussels, the Museum du Nord is also lighted in this way, and they are now occupied in opening for that town a central station. In Frankfort, there are two establishments, each burning 60 lamps. In Sarreguemines, 400 lamps are at work. In Brünn, the new theatre will be lighted by 900 lamps, and further orders are being given to the company. In Steier, near Linz, they have just arranged for 60 lamps, and in Vienna, three places of the same importance are now lighted by their system. Finally, in Milan, they have arranged to light up two places, and in Bologna a large mill will be supplied with their lights.

Besides supplying these places with the Edison lamps, a few others have been lighted by other companies, who made their arrangements direct with the inventor. Among these we may mention the lighting of a large cornmill, in Gillamont, Switzerland, of which we spoke in our number of June 24th (*See* Electrical Review of July 1st). We intend shortly to give a description of the works, where Mr. Edison's apparatus are manufactured, situated in Ivry, near Paris, and which are at present in full swing under the superintendence of Mr. Batchelor, the assistant of Mr. Edison, and who, with Mr. Otto A. Moses, organised last year his exhibition in the Palais de l'Industrie.

Electric Light in Salford.—After an installation of four years' standing which has given entire satisfaction and been entirely free from repairing expenses the firm of J. Bury, dyer and finisher, Salford, has made an addition of two of the British Electric Light Company's Gramme machines. The making-up room, which was formerly lit by 90 gas burners, rendering the atmosphere of the room very unpleasant during night-work, has been fitted with 60 incandescent lamps, which obviate the above inconvenience. In the room is fixed a regulator, which enables the foreman to put out any number of lights he requires. The dye house is illuminated by two Brockie arc lights, which enable the foreman to match his colours at night as well as in daylight. The whole of the arrangements were carried out by Messrs. H. Bury and G. Tyndall, Electric Light Engineers and Agents for the British Electric Light Company, Manchester.

Underground Electric Light Wires.—The *Athenæum* states that Professor Houston, of Philadelphia, reports, after a series of elaborate investigations, that wires for the electric light are in every way less liable to accident if placed in the earth than if placed overhead. The municipal authorities, therefore, of Chicago have determined that the wires for lighting their city shall be placed underground.

The Jablochkoff Electric Light.—The Thames Embankment and other places lighted from the station of the Jablochkoff Company have been temporarily bereft of the services of that effective and wonderfully reliable system owing to an accident to the steam engine. It was stated when the lamps went out on Monday evening last that two or three days must elapse before they could be again put in action.

New Electric Lamps.—At 374, Euston Road, N.W., is to be seen an arc electric lamp called the "Diamond." It is extremely simple and light, and its actuating mechanism appears likely to compare favourably with any at present known. As we could not gain much information concerning the object of the exhibit in the Euston Road, not even to the extent of the inventor's name, we do not now propose to do more than merely allude to it.

We have recently had an opportunity of seeing in action

the arc lamps of Messrs. F. M. Rogers and Jarman, and also the dynamo-electric machine of the latter. We cannot yet describe them, as certain matters connected with the patents are not quite settled. The main objects aimed at, as far as both machine and lamps are concerned, has been to simplify their construction, and so produce them at a lower rate than is now paid for these articles.

Mr. Jarman is, we believe, now experimenting on an incandescent lamp devised by himself, so that it is shortly expected that the above-named inventors will have a complete system on view. We shall reserve all criticisms on the points involved in the respective lamps and machine for a future occasion.

THE ELECTRIC LIGHTING BILL.—In the Parliamentary discussion on this Bill, Colonel Makins asserted his belief that of the aggregate capital of £13,000,000 or £14,000,000 raised by the 55 electric lighting companies registered lately, the greater proportion had been expended on inventors and promoters.

ELECTRIC LIGHT SHARES.—Various statements have been put forth to account for the late rapid fall in Brush and Hammond electric light shares. One was to the effect that it is in consequence of the insecurity of the patent rights of the Brush apparatus. In the money market article of the *Standard* of last Wednesday, it says that the fall is due to the results disclosed at the meeting of the Brush Company. It appears that the available balance in hand is £245,000, which would be sufficient to enable a return of the paid-up capital, instead of half as much more as the market had anticipated. Can it be that the rules and regulations concerning fire risks from the electric light, issued by the Society of Telegraph Engineers and of Electricians, explain it? Rule 20 reads in part:—There should never be a difference of potential of more than 200 *volts* between any two points in the same room.

THE ELECTRIC LIGHT IN THE CITY.—At the fortnightly meeting of the Commissioners of Sewers held last Tuesday, Mr. Pannell presented a report from the Streets Committee relative to the Edison electric light on the Holborn Viaduct, and stating that they have arranged for the same to be continued for a further period of six months at the cost of gas.

The report was adopted.

Mr. Bedford said there was a magnificent light on the Holborn Viaduct, close to St. Andrew's Church. He wished to know if the engineer could give him any information on the subject?

The engineer said he supposed it was some recent experiment, but it had not been notified to him.

The clerk (Mr. Blake) read the report of the Streets Committee, which has been printed and circulated, on their proceedings relative to the applications made for an extension of the experiments in electric lighting; submitting an abstract of tenders received, and expressing an opinion that it is not desirable to proceed further until Parliament has decided the principle upon which electric lighting generally shall be permitted.

Mr. Innes thereupon moved, "That the report be referred back, with instructions to forthwith carry out the electric lighting through the tendering companies, with the light of private lighting in the districts for three years added to their contracts, reporting in the first instance on the cost of the street lighting after tenders have been made on the footing of the right of private lighting." He traced the action of the commission in connection with the electric light from the commencement, and urged that something definite should now be done. They were told that this was a speculation, but every improvement was a speculation in the first instance. The right of private lighting had been practically conceded in the case of the Edison company, who had commenced operations on the Holborn Viaduct. The other companies meantime were handicapped. They were told to wait for legislative action, but no legislation was required. He was averse to the commission making experiments, but contented that power should be given to the companies to make experiments without further delay. The divisions in the committee would prevent them coming to any decision, and he therefore thought the subject should be settled by the commission.

Mr. Morrison seconded the motion.

Mr. Shooter opposed the amendment, trusting that the commission would agree with the committee in their report. A discussion ensued, in the course of which Mr. W. J. Scott twitted the commission with trying to obstruct electric lighting. He had no hesitation in saying that the opposition to the amendment came from gas company interest. Mr. Shaw denied that there was any truth in the accusation made by the previous speaker; and as for the commission being obstructives, he pointed out that they had been the first to give an opportunity for experiments being made with the new light. The discussion was continued by Mr. Waller, Mr. Ashby, and several other members, and eventually the amendment was lost upon a show of hands being taken. A division was demanded, and the numbers were—for the amendment, 6; against, 17. The original motion to agree with the committee in their report was then agreed to, and after transacting some other business the commission adjourned.

INCANDESCENT ELECTRIC LAMPS.—A preliminary announcement emanating from the London and Provincial Electric Light and Power Company, to the effect that a limited company is now in course of formation for supplying Kensington, Hammersmith, Notting Hill, and other districts with the electric light by means of the Chertemps arc and British incandescent lamps, speaks thus of the latter: "The signal success which has attended the lighting of Stafford House by these incandescent lamps points to this as the most complete system."

THE "MORNA" CABLE STEAMER.—We read the following in the *Oban Telegraph* of the 14th inst.:—

The ss. *Morna*, of Leith, commanded by Capt. Howling, arrived here on Tuesday morning on her way to repair the broken cable between Oban and Mull. This steamer is fitted up with all the necessary appliances, and, in addition to the crew, there are thirty cable men and a large staff of electricians on board. On Tuesday afternoon the injured cable was tested, and the fracture found to exist in the vicinity of the Lady Rock. After completing the repairs on the Mull cable, the *Morna* proceeds to Yell Sound, in Shetland, for a similar purpose.

With reference to the fracture on the Mull cable, it may be stated that on examination it was discovered that the cable had been maliciously cut, in all probability by the crew of some vessel whose anchor had fouled, and, in order to save some slight delay in clearing the submarine line, a process easily accomplished. In view of the serious consequences to the country in expense and inconvenience, this must be looked upon as a most aggravated offence, and one deserving of heavy punishment. The cable was thoroughly repaired yesterday, and telegraphic communication resumed. The operations, which have been so speedily and successfully accomplished, were under the supervision of Mr. David Lumsden, Mr. Albrow, and Captain Hayward, electricians of the Submarine Department G. P. O., while Mr. Wright, the energetic local superintendent, lent intelligent and useful aid in shore work. Captain Howling, the commander of the *Morna*, is a most experienced navigator, whose skilful handling of his vessel greatly facilitates the progress of the work for which the steamer has been chartered. From later information we find that the cable in Yell Sound was made good on the afternoon of Tuesday last.

THE TELEGRAPH STEAMER "INTERNATIONAL."—The India-Rubber, Gutta-Percha, and Telegraph Works Company received on the 18th inst. a telegram from Mr. Theophilus Smith, engineer-in-charge, informing them of the successful completion of the repairs of the Havana-Key West Cable, for which the *International* had been chartered by the International Ocean Telegraph Company of New York. After coaling and provisioning the *International* leaves Key West for London.

NEW ZEALAND TELEGRAPHS.—The business of the New Zealand Telegraph Department during the quarter ending December, 1881, showed a satisfactory increase on that transacted during the corresponding quarter of 1880, the total number of paid messages for the former being 308,462—value £20,404—and for the latter, 263,908—value £17,188. The increase of messages was thus 44,554, and of receipts, £3,216. The Government telegrams numbered 51,734, the value being £5,654, or a decrease in number of 10,514 and in value of £1,140 on the December quarter of 1880.

A NEW METHOD OF TELEGRAPH TRANSLATION.—Sir James Anderson and Mr. Benjamin Smith, of the Eastern Telegraph Company, have introduced a system of personal translation by means of which the dispatch of messages is facilitated, delay avoided, and greater accuracy obtained. At present, as is well known, messages are written down by a clerk as they are received at the end of each section, and then passed on to another clerk, who transmits them over

the next section, and so on till the messages reach their destination. The new method is to cause the clerk who receives the messages, say from section A, to send them at the same time over section B, so that while he is reading the messages from the receiver he is transmitting them to the next relay. The advantages of this system are obvious. There is no writing down of the messages at the relay stations, and passing on to other clerks; the whole of the attention of the operators can be given to the receipt and transmission of the messages, and greater accuracy thereby attained. Where simplex is worked one clerk will take the place of two, and where duplex is in operation two men will in several instances replace six. The saving thus effected in the expense of the *personnel*, stationery, and apparatus will not be inconsiderable. We understand the system has already been adopted on the submarine lines of the Eastern, Eastern Extension, and South African Telegraph Companies.

THE PROPOSED ATLANTIC CABLES. — The *Illustrated London News* of Saturday last thus comments on the proposed Atlantic cables :—"Yet further competition is in store for the owners of the Atlantic telegraph cables. The controllers of the Baltimore and Ohio Railroad have decided to lay two cables across the Atlantic, one to England and the other to Portugal. It is surprising how the money is found for such enterprises, as of the many cables which have been laid for competing purposes not one has long remained outside, and all are now either owned by the original company or worked in unison with it; while every £100 spent in laying such cables speedily comes to be very much less than that. The result has so far been that the public has not derived the advantages usually following competition, while stockholders have lost in both capital and income from the excessive number of cables employed in the service. The fruit of this experience is that some degree of monopoly is desirable in the case of cables. Concessions for terms of years have been granted to the companies serving most of the other routes, but the Atlantic is quite open. The public is as well and economically served on the monopoly routes as on the open. The capital sunk in the open is at a discount of 50 per cent., that in the busiest of the monopoly routes is at a premium. With these facts before them European investors must indeed be foolish if they provide any of the capital for the new cables."

TELEGRAPHIC COMMUNICATION WITH THE SUEZ CANAL.—It is said that the means of maintaining direct telegraphic communication with the Suez Canal are now under the consideration of Her Majesty's Government.

ELECTRICITY IN WARFARE.—We understand that concurrently with the field telegraph and electric light, the telephone is to be tried in the Egyptian campaign.

FORMS FOR TELEGRAMS.—At a meeting of the Greenock Chamber of Commerce, held on the 13th inst., it was stated that efforts had been made to induce the post-office authorities to introduce a larger telegram form than that now in use. The directors were now able to report that the postmaster-general had given instructions that telegrams will not hereafter require to be written on special forms but may be handed in on any sheet of paper; also that telegrams of an urgent nature will be transmitted at any hour during the night from the Greenock post-office to any office having night officials on payment of an extra charge of one shilling.

SECRECY OF TELEGRAMS.—Replying to Mr. Pulestown, in the House of Commons, on Thursday, the 13th inst., Mr. Fawcett said that the practice which had hitherto prevailed in the post-office was not to give up telegrams, except on the applications either of the sender or receiver. Some doubt, however, has arisen whether they had legal power thus to give up telegrams, and in view of this legal doubt he proposed in the Post-office Bill shortly to be introduced to insert a clause which would place telegrams, with regard to secrecy, in the same position that letters now were.

TELEPHONES IN ENGLAND.—It is well known that the telephonic industry in America has made enormous strides, while in England the matter has made but little progress, Now however that the granting of the licences for the formation of telephone exchanges has been decided upon by the Postmaster-General, there appears to be no reason why we should not soon be on level terms with our American cousins. The towns of England are comparatively such short distances apart, that we have unusual facilities from this fact alone. Again, the undulatory current is not claimed in this country, but it is the United States. Therefore we may soon expect to see England to the fore with the telephone.

THE TELEPHONE IN ALEXANDRIA.—The *Standard* correspondent, in a telegram dated Sunday last, says police-stations are now established in all parts of the town, and the Oriental Telephone Company are laying down wires to place them in connection with each other.

THE WORLD AND THE TELEPHONE MONOPOLY.—In its City Notes, the *World* says :—Another new Telephone Company is announced. We hope, at all events, it will supply something good and cheap, for the present monopolist in that line is anything but a satisfactory servant to the public. Complaints are incessant, either that its instruments tell too much, lets those hear secrets who should not hear them, or that they will not work at all.

THE TELEPHONE IN SCOTLAND.—The National Telephone Company (Limited) have established telephone communication between Newport, Fife, and their exchange in Dundee. A wire is led across the standing portions of the Tay Bridge, and in the gap an 8-wire cable has been laid. From the south end of the bridge the wire is carried along the public road to the village. In Newport an exchange will be opened, the subscribers to which will, in addition to the convenience of conversing with each other, have the advantage of speaking to any subscriber to the company's Dundee exchange. The exchange at Newport will be open from 6.30 a.m. to 11 p.m. Several subscribers have already been obtained. Tayport is to be similarly treated. The National Telephone Company are to supply the contractors for the new Tay Bridge with telephone communication between the works on the one side of the river and those on the other side.

TELEPHONE SHARES.—It might almost be supposed that the decision of the Postmaster-General in regard to telephone licences had leaked out before his statement in Parliament, as on the preceding day the shares of the United Telephone Company fell £1 per share. Altogether they have fallen recently from 16 to 10¾; but the last quotation, on the 19th inst., was 11¼—11¾.

THE LIBRARY OF THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.—Mr. A. J. Frost has just succeeded in acquiring for the Library of the Society of Telegraph Engineers and of Electricians a copy of the fine work Vincentius (Belloracensis), "Speculum Naturale," 2 vols. folio, 1473-76. Vincentius was Bishop of Beauvais, and wrote about the year 1250, and the work now referred to contains probably the earliest *printed* allusion to the polarity of the magnetised needle and its use in navigation. As a specimen of typography alone, independent of its literary interest, it is well worth a visit to the library, and we consider that Mr. Frost has been fortunate in obtaining this interesting and valuable work as an addition to the already important collection under his care. In these days of business activity such collections are apt to be forgotten or overlooked, and it is gratifying to feel that some one is giving attention to the completion of such important collections as those possessed by the society and Mr. Latimer Clark, and which cannot fail in the future to increase in value and interest. While referring to the library of the society we may add that an important and most complete list of works on electric lighting will be found in Kuhn's "Handbuch der angewandten Elektricitätslehre." 8vo. Leipzig. 1866.

THE AWARDS AT THE CRYSTAL PALACE EXHIBITION.—In our correspondence columns will be found a letter referring to these awards, and as we are frequently asked when they

are to be made we should be glad if any of our readers can give information on the subject. Surely sufficient time has elapsed. Perhaps the Honorary Council of Advice will give a little consideration to this matter.

THE ELECTRICAL INSULATOR MANUFACTURING COMPANY.—The operations of this company form a district branch of electrical work, but whether such a business will be of a sufficiently wide nature to justify the company's belief remains to be seen. There are certain statements contained in the prospectus which we feel called upon to challenge. In regard to the manufacture of insulators for home consumption we believe the postal authorities are almost the only people who require insulators, and these, we believe, are supplied mainly by one firm only. The supply required by the railway companies is but small, as they are generally only wanted for maintenance purposes. Telephone wires will probably soon be wholly laid underground. Therefore we think that the glowing statements of the promoters concerning the enormous business to be done at home in insulators must be taken *cum grano salis*. The scientific reports on the superior nature of this clay are not altogether in accordance with facts—that is to say, the importance of a material free from iron so far as insulators are concerned is much exaggerated. We believe that the several well-known firms of insulator manufacturers are quite equal, with their long experience, to supply a very largely increased demand at any moment they might be called upon to do so. We notice that the company purposes manufacturing other goods beyond those of an electrical nature; but the title of the company and the wording of the prospectus naturally seem to point to the conclusion that it is promoted to take advantage of the present electrical craze. We do not, however, consider that the statements with regard to the company's connection with the electrical industry are by any means exact.

A NEW ELECTRIC MOTOR.—M. Paul Jablochkoff, of electric light celebrity, has paid a recent visit to London. During his stay he submitted to some of his scientific friends a new electric motor, which possesses all the merits which characterise M. Jablochkoff's inventions—viz., extreme simplicity. If what we hear is confirmed, distribution of power by this new motor will become practicable at rates which would hardly have been thought possible by any of the means at present known. We need hardly add that this invention becomes, as a matter of course, the property of the newly-formed company bearing M. Jablochkoff's name. We believe that we are correct in stating that the firm of M. Breguet will work the French patent for this new motor.

PERSONAL.—Mr. Johnston, the well-known editor and proprietor of the New York *Operator*, has recently been visiting London. This is the first time we have had the pleasure of meeting Mr. Johnston, and we can fully endorse from our personal experience the opinions previously formed of his frank and humorous nature, which is so apparent in his writings. Mr. Johnston is not a stranger to London, and his first experiences in electrical matters were gained in the mother country. We trust that his trip will be throughout of an enjoyable kind, and that on his return he may reap still further benefit from the journal he has so long successfully and ably conducted.

TO ELECTRIC WORKS COMPANIES.—It may be of service to some of the new companies to direct their attention to the advertisement for the sale of premises and plant suitable for such works, particulars of which are given on one of our supplementary pages.

THE INTERNATIONAL ELECTRIC AND GAS EXHIBITION.—This proposed exhibition at the Crystal Palace is to commence in October next, and continue till the end of Easter week, 1883. Intending applicants for space should apply before the 1st of August. A limited amount of engine-power will be supplied, as far as it goes, to exhibitors desirous of taking advantage of this offer. Applications must, however, be made before the above date. Whatever work may be necessary to place and decorate exhibits must be done by the exhibitors at their sole expense, and always subject to the supervision and approval of the directors. We should imagine that as far as those connected with electric lighting are concerned, their thoughts will turn more in the direction of doing successful work during the forthcoming winter and paying dividends on capital employed. Exhibitions are very well from scientific or commercial points of view once in awhile; but it is possible to have too much of a good thing. That just closed at the Crystal Palace answered its purpose; but those exhibitors fortunate enough to float companies on the strength of their efforts in this direction will not, we should imagine, feel inclined to face a second heavy expense in so short a time, but will rather devote all their energies to the formation of a good and profitable business.

EXHIBITION OF PRACTICAL ELECTRIC DEVELOPMENT.—It is preposed to devote the buildings and premises of the Royal Aquarium, at Westminster, to the above purpose, from November 1st next to March 1st, 1883. It is instituted for the purpose of practically developing subsidiary points in the economical use of electric energy. Prizes are to be given for eighteen different subjects, and amongst them may be named:—The best systems of storage and generator for railway trains; the best systems of storage batteries; the best electro-motor for stationary or tram-car work: (*a*), absorbing ½ horse-power; (*b*), 2½ horse-power; (*c*), 5 horse-power. The best system of dynamos for compensating change in resistance of external circuit, &c.; the best electric meter; the best system of street mains or leads; the best photometer, and various other matters. The electric engineer to the proposed exhibition is Mr. W. D. Gooch, of 17, Royal Exchange, London.

TO OUR READERS.—We beg to inform our friends and subscribers that Vol. X. of the ELECTRICAL REVIEW can now be had handsomely bound, by applying to Messrs. Haughton & Co., 10, Paternoster Row, E.C. Cases for binding can also be obtained. For particulars see advertisement on page 11 of supplement.

TO MEDALLISTS OF THE PARIS ELECTRICAL EXHIBITION.—Electrotypes of the Paris medal may be had for the purpose of insertion in advertisements and trade circulars, &c., at moderate rates, on application to the manager of the ELECTRICAL REVIEW, 22, Paternoster Row, E.C.

NEW COMPANIES REGISTERED.

WEST MIDDLESEX ELECTRIC LIGHTING COMPANY (LIMITED).—Capital £100,000, in £5 shares. Office, 14, King Street, West Hammersmith. Objects: To purchase a licence acquired by Charles Cordingley from the British Electric Light Company (Limited), for the use of the Gramme dynamo machines, the British incandescent lamp, and Brockie's arc lamp. The purchase consideration is £12,500 in cash and £12,500 in fully paid shares. Signatories: J. H. Swann, C.E., 110, Cannon Street, 20 shares; W. J. Colley, Mill Hill, N.W., 20 shares; C. J. Parker, Hammersmith Road, 20 shares; J. Barnes, Hammersmith Road, one share; F. Wingrove, Hammersmith Road, one share; W. Pickersgill, 87, Arlington Road, Regent's Park, 10 shares; G. H. Hutchinson, 1, Laurence Pountney Hill, E.C., one share. Directing qualification, 20 shares; the signatories nominate the first directors. Remuneration, £1,000 per annum. Registered 13th inst. by Watson, Son, and Room, 12, Bouverie Street, E.C.

ELECTRICAL INSULATOR MANUFACTURING COMPANY (LIMITED).—Capital £100,000, in £1 shares. Objects: To carry on business as potters and manufacturers of electrical insulators in any material and of every kind. Signatories (with one share each): R. Marsh, 79, York Road, Lambeth; C. Bate, 78, Alexand Road, South Hampstead; C. E. Hewitt, 10, Thornsett Road, Anerley; T. J. Bradfield, 193, Clapham Park Road; E. H. Wilson, 10, Buckingham Street, Strand; J. Evans, 2, Crogsland Road, Haverstock Hill; S. H. Barlow, 38, Warbeck Road, Shepherd's Bush. Directing qualification, 100 shares; remuneration, £500 per annum, with an additional £250 after 10 per cent. per annum dividend has been paid. Registered 13th inst. by Pyke and Minchin, 31, Lombard Street.

NEW PATENTS—1882.

3171. "Governing marine engines by electricity." W. W. GIRDWOOD. Dated July 5.

3172. "Voltaic batteries." J. IMRAY. (Communicated by P. Jablochkoff.) Dated July 5.

3173. "A new or improved apparatus for recording speech." J. IMRAY. (Communicated by A. Gentilli and L. C. Alexander.) Dated July 5.

3175. "Improvements in the materials for and in the construction of electric insulating apparatus and in the means of preserving the same." W. F. BOTTOMLEY, J. H. BARRY, and J. J. LUNDY. Dated July 5.

3181. "Dynamo-electric machines." A. LÉVY. (Communicated by D. Lachaussée.) Dated July 5.

3190. "Electric and other tell-tales for indicating and registering." A. SCHWEITZER and T. LAWRIE. Dated July 6.

3204. "Apparatus for the generation, regulation, and utilisation of electric currents." W. R. LAKE. (Communicated by G. Thomson.) Dated July 6.

3217. "Machinery or apparatus for applying anti-induction coverings to insulated electrical conducting wires." G. S. PAGE. (Communicated by J. M. Stearns.) Dated July 7.

3219. "Supports for underground electrical conductors and their conduits." G. S. PAGE. (Communicated by J. M. Stearns.) Dated July 7.

3221. "Secondary batteries or accumulators." R. H. WOODLEY and H. F. JOEL. Dated July 7.

3226. "An improved electro-magnetic motor." E. TOYNBEE. Dated July 7.

3233. "Electric clocks." J. P. A. SCHLAEFLI. Dated July 7.

3236. "Arc electric lamps." F. M. ROGERS. Dated July 7.

3240. "Manufacture and preparation of plates for electric accumulators." T. S. SARNEY and J. M. ALPROVIDGE. Dated July 8.

3244. "Incandescing electric lamps." T. J. HANDFORD. (Communicated by C. A. van Cleve.) Dated July 8.

3255. "Improvements in the construction of incandescent electric lamps and in apparatus therefor, which apparatus is also applicable for other like uses." J. H. GARDINER. Dated July 8.

3263. "'Blocks' or 'cylinders' for incandescent lights." G. DAVIES. Dated July 10.

3271. "Electrical meters." T. J. HANDFORD. (Communicated by T. A. Edison.) Dated July 10.

3273. "Magnets." J. S. FAIRFAX. Dated July 10.

3279. "Electric lamps." J. S. BEEMAN. Dated July 11.

3281. "Arrangement and application of electrical conductors." F. JACOB. Dated July 11.

3296. "An improvement in preparing the sheet lead electrodes of secondary batteries with a view to their rapid formation." A. M. CLARK. (Communicated by G. Planté.) Dated July 11.

3303. "Secondary voltaic batteries." F. W. DURHAM and P. WARD. Dated July 12.

3315. "An improved method and process of and apparatus for coating or covering wire with copper or other metal (telegraph wire)." W. R. LAKE. (Communicated by T. Wallace.) Dated July 12. (*Complete.*)

3318. "Improved means and appliances or apparatus for producing or evolving, collecting, storing, and utilising electric energy for lighting and for general purposes, partly applicable for use in combination with coal gas." J. L. PULVERMACHER. Dated July 12.

3322. "Apparatus for producing, measuring, and distributing electric currents." J. M. M. MUNRO. Dated July 13.

3330. "Electric lighting and power distributing systems." S. PITT. (Communicated by E. T. Starr and W. J. Peyton.) Dated July 13. (*Complete.*)

3331. "Improved apparatus for making and breaking electric circuits." J. R. GIBSON. Dated July 13.

3334. "Improvements in the construction of dynamo-electric or magneto-electric and electro-dynamic machines and in governing or regulating the same." R. MATTHEWS. Dated July 14.

3335. "Telephones." S. M. YEATES. Dated July 14.

3339. "Arc regulator lamps." R. E. B. CROMPTON. Dated July 14.

3349. "Incandescent electric lamp appliances." J. S. BEEMAN. Dated July 14.

3350. "Electric lampholders and switches therefor, or for other purposes." J. S. BEEMAN. Dated July 14.

3351. "Improvements in apparatus for automatically shunting electric currents, and in apparatus for breaking circuits." J. S. BEEMAN. Dated July 14.

3355. "Means or apparatus employed in or for supplying electricity for light power and other purposes." T. J. HANDFORD. (Communicated by T. A. Edison.) Dated July 14.

3370. "Apparatus for automatically indicating the presence of fire or heat by electricity." E. EDWARDS. (Communicated by B. Carré.) Dated July 15.

3380. "An electrical haulage system and apparatus connected therewith." W. E. AYRTON and J. PERRY. Dated July 17.

3382. "Electric light appliances." H. J. HADDAN. (Communicated by G. H. A. Seymour.) Dated July 17.

3385. "A new or improved electric arc lamp." L. A. GROTH. (Communicated by C. P. Jürgensen.) Dated July 17.

3391. "Improvements in the manufacture of wire and in the apparatus employed therein." T. MORGAN. (Communicated by E. J. Levavasseur.) Dated July 17.

3393. "Electric lamps." J. D. F. ANDREWS. Dated July 17.

3409. "Plates for secondary batteries." W. TAYLOR and F. KING. Dated July 18.

3414. "Electric telegraph signalling apparatus." H. E. NEWTON. (Communicated by O. Zadig.) Dated July 18.

3418. "Improvements in electric arc lamps and in regulators therefor; applicable also to regulating electric currents for other purposes." S. Z. DE FERRANTI and A. THOMPSON. Dated July 18.

3419. "Dynamo electric machines or electric generators." S. Z. DE FERRANTI and A. THOMPSON. Dated July 18.

3420. "Dynamo-electric machines." W. P. THOMPSON. (Communicated by P. Payen and A. Sandron.) Dated July 18.

ABSTRACTS OF PUBLISHED SPECIFICATIONS, 1881.

4780. "Insulating electric conductors, &c." A. T. WOODWARD. Dated November 1. 6d. Relates to the mode of rendering the whole of the conductors and the test boxes entirely water and air proof, so that the insulation cannot be injured by moisture, and access can be had to the wires when required for the purpose of testing the same, and for taking off any lateral connections. Fig. 1 is a vertical section of the insulated telegraph conductors at two of the test or connection boxes, and fig. 2 is a cross section, at the line, *x*, *x*. The case or tube into which the electric conductors are laid is to be of any desired size or shape, according to the number of conductors it is to contain, and it is preferably of wood, but may be of metal or

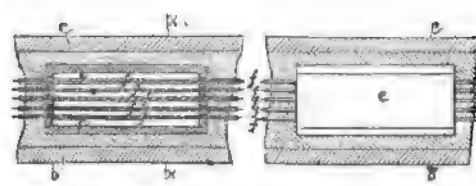


FIG. 1.

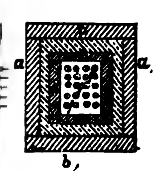

FIG 2.

earthenware. Such a box is shown as square sectionally, with sides, *a*, bottom, *b*, and movable top, *c*. There is introduced into the bottom of the case, *a*, *b*, *c*, a layer of waterproof insulating material, such as hereafter described, or any other suitable bituminous or water-proof compound may be employed. At suitable distances apart there are testing, or connection boxes, *e*, introduced within the case, *a*, *b*, *c*, and the wires, or conductors, *f*, *f*, pass through holes at the ends of these boxes. The water-proof insulating material is introduced in a melted state into the case, *a*, *b*, around the electric conductors, and also entirely around the testing or connection boxes, *e*. In applying the water-proof insulating material it is preferable to introduce a layer on the bottom of the case, then place thereon the lowest range of parallel conductors, then another layer of waterproof insulating material, and another range of parallel wires, and so on. The water-proof insulating material flows all round the testing or connection boxes, and hermetically seals the same, and renders the box perfectly water and air tight. Where there are lateral connections they will usually be made before the cover of the box, *e*, is applied, but when these lateral connections have to be made to a previously laid cable the cover of the external case is removed, and the water-proofing material at the testing-box is removed, the insulating material broken up, and the cover of the testing-box removed, to give access to the electric conductors for testing or making lateral connections, after which the box is closed and hermetically sealed by the melted insulating material. The water-proof and insulating material which it is preferred to employ is prepared as next described. The inventor makes use of silica, such as glass, or quartz, in the form of a very fine powder, and vegetable or mineral resin or pitch. This latter substance should also be ground fine and thoroughly mixed with the silica, and there is added to the same wax, such as paraffine, beeswax, or spermaceti, and also oil, such as boiled or raw linseed oil. It is preferred to use about 66 parts by weight of silica to 34 parts of resin or pitch, and 26 parts of wax, more or less, and about three parts of oil. These are all thoroughly combined in the presence of sufficient heat to liquefy the resin; the mass is to be carefully and thoroughly stirred to render it homogeneous.

5185. "Electric lamps." E. G. BREWER. (A communication from abroad by A. G. Waterhouse, of New York.) Dated November 28. 1s. Relates to electric lamps of the type in which carbon sticks or pencils are fed towards one another as they consume, the movement being controlled by a clutch or by wheel work, or by other suitable means, the action of which is governed by an electro-magnet or magnets. This invention consists, first, of certain novel con-

structions and arrangements of governing electro-magnets, of improved clutch or clamp devices for governing the descent of the carbon rod, and of a novel safety shunting device. Fig. 1 is a side view of a lamp having one arrangement of the electro-magnets, and showing also the safety shunting device. Fig. 2 is a top view of the electro-magnets partially in section. Figs. 3, 4, and 5 illustrate the clutches which are actuated by the movable electro-magnet. Fig. 6 is a detail of construction of the lamp illustrated in fig. 1. Figs. 7, 8, 9, and 10 illustrate modifications. Referring to figs. 1 and 2, A represents the base plate of a lamp upon which the enclosing

FIG 1

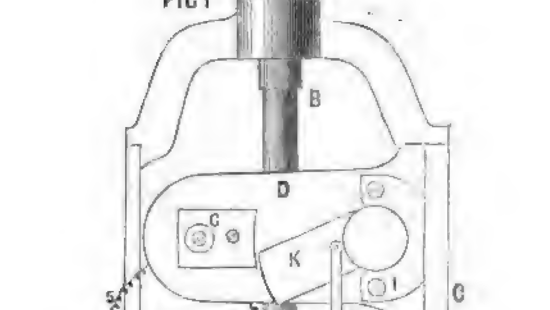

FIG 2

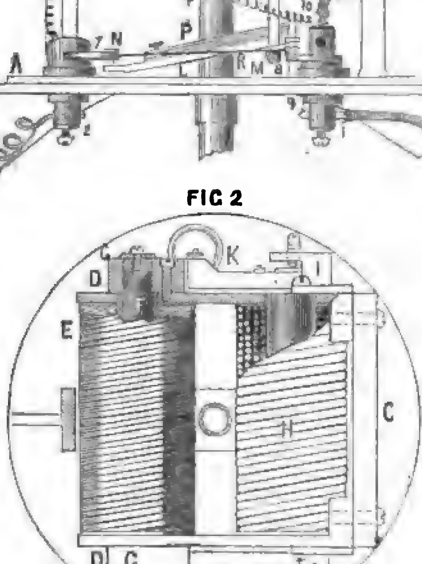

FIG 5

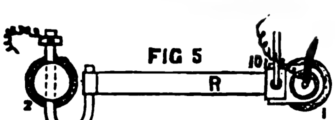

FIG 3

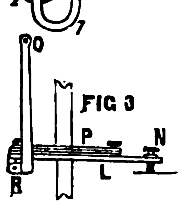

FIG 4

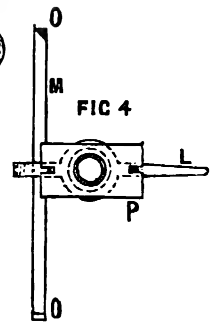

FIG 6

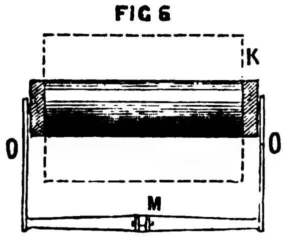
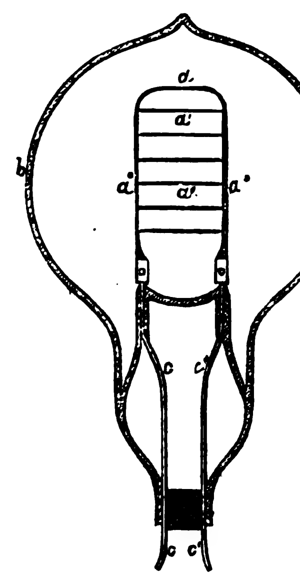


frame and the supporting standards for the operating portions of the lamp are mounted; B represents the carbon rod or carrier; C is an upright plate secured to base, A, and having bolted to it brackets, D, D, in which the electro-magnets are supported; E represents an electro-magnet wound with coils of comparatively fine wire, which are included in a derived or branch circuit around the arc. The core of said electro-magnet is represented at F as supported in the bracket, D. G, G, are pole pieces connected to said core upon the outside of the bracket, and extending at right angles from the core towards the projecting pole pieces of a similar electro-magnet, H, wound with coarser wire, and with its coils in direct circuit with the carbons and the arc. The core of the latter electro-magnet is pivoted from brackets or clips, I, I, secured to brackets, D, by screws or other means, and is provided with rectangular pole extensions, K, K, projecting towards the pole pieces, G, G, and adapted to swing in close proximity to the latter, as indicated in fig. 1. The coils of magnets, H, E, are so wound and connected to the general circuit that the pole pieces G, K, in proximity to one another would be naturally of the same polarity, so that they would repel one another. The action or influence of the main circuit coil, H, is however sufficiently strong to overbalance the opposing influence of the coils of E, so as to cause the core of E to be polarised by induction from the core of H, so that when the lamp is working there is a positive attraction between the poles. When however the length of arc increases so as to cause more current to circulate in the derived circuit coils, E, the latter exerts a greater depolarising influence, and thus causes a diminution in the attraction between the poles so as to allow the poles, K, to drop away, and through any suitable means to release the carbons and allow it to feed. The means here shown consist of a clutch engaging with the carbon rod or carrier, B; said clutch consists of a perforated lever, L, hung at one end from an arm, R, best seen in fig. 3, supported from a crossbar, M, and resting at the other end by means of a set screw, N, passing through it upon the base plate, A. The bar, M, is supported by links, O, hung from the movable pole pieces, K, as shown in fig. 6. The edges of the perforation in L, or in a series of superposed steel plates, P, supported on the plate, L, and to be presently described, is adapted to engage with the carbon rod, B, when the plate, L, is tilted, so as to stop the movement downward of the rod, or to lift the rod so as to establish the electric arc. As thus constructed the lamp operates as follows:—When no current is passing the pole pieces, K, and the supported clutch rest by the action of gravity or a spring in a position where the clutch, L, does not engage with rod, B. The carbons are then in contact. When the current passes, the poles, K, and G, are attracted owing to the preponderating effect of the current circulating in coils, H. The clutch is thus tilted and lifted, raising the carbon rod, B, and separating the carbons to a distance dependent upon the adjustment of the screw, N, or of a suitable retracting spring acting upon K. When the arc lengthens by reason of waste of the carbons, more current circulates in E, and its depolarising influence is increased, so that the attraction between K and G is diminished and the carbon rod is thereby released, so that the carbon feeds downward.

5233. "Utilisation of electricity for lighting, &c." W. R. LAKE. (A communication from abroad by J. S. Williams, of Paris.) Dated November 30. 1s. Relates to the utilisation of electricity for lighting or other purposes, and apparatus therefor or to be employed in connection therewith, also to the means for producing or manu-



facturing various parts of such apparatus. The figure is a centra section of one form of the improved lamp in which a conductor is employed having a series of transverse filaments. The invention also refers to electrical warming apparatus.

5261. "Secondary batteries." H. E. NEWTON. (A communication from abroad by Ernest Volckmar, of Paris.) Dated December 1. 6d. The object of this invention is to obtain secondary batteries which will give, with a minimum of weight and dimensions, the maximum of electrical energy. The improvements are as follows:—The inventor arranges a certain number of secondary couples in a single vessel. The plates are placed by preference horizontally one above the other. In this way there will be as many elements as there are plates, less one, each plate being at the same time the positive electrode of one couple and the negative electrode of the following couple, with the exception of the first and the last plates, which form the poles of the battery. The horizontal arrangement offers one peculiar advantage:—If one of the electrodes of this nature becomes disintegrated from any cause the disintegrated particles of a superior plate will fall on to the plate which is immediately below without causing the least disturbance, because these particles will unite themselves with the active matters of the support upon which they have fallen and identify themselves with them under the influence of the charging current.

5295. "Mechanism for regulating the feed of electrodes in electric lamps." H. E. NEWTON. (A communication from abroad by Alphonse Isidore Gravier, of Paris.) Dated December 3. 6d. Relates to the regulation of the electrodes in that class of electric lamps in which clockwork is employed, the object being to produce a more delicate regulation of the electrodes than has been heretofore obtained. For this purpose two electro-magnets are used to control the movements of an oscillating locking bar, which engages with the fly and scape wheel of the clock mechanism for the purpose of locking and releasing the same, and thus controlling its movements. The carbon electrode to be regulated is carried by a vertical rack-bar, which forms the propelling weight of the clock, and thus on the release of the scape wheel the feed of the carbon instantly commences. A tendency is given to this locking bar to drop into the locking position by the pressure of a light spring, a counterweight, or its equivalent. The electro-magnet situate on the weighted side of the locking bar is coiled with a comparatively thick wire and is set in the main circuit of the lamp. The office of this magnet, which is the more powerful one, is to draw forward the oscillating bar and retain it in its locking position. The electro-magnet on the opposite side of the locking bar is coiled with a fine wire to offer a greater resistance to the passage of a current than the coils of the more powerful magnet. The greater resistance magnet is placed in a secondary or derived circuit, one of its terminals being connected with a terminal of the other magnet. The effect of this arrangement is that when the arc has increased to such an extent as to offer an undue resistance to the passage of the current in the main circuit, an increased proportion of the current will pass to the derived circuit, thereby increasing the attractive power of the electro-magnet in that circuit to an extent that will enable it to pull over the locking bar, release the scape wheel, and set the clockwork in action. So soon as the resistance in the main circuit has decreased by the approach of the carbons, the electro-magnet in the circuit will regain its superior attraction and return the oscillating bar to its original position. Adjustable stops are provided for limiting the motions of the locking bar.

5303. "Telephones." ISAAC BURTON. Dated December 5. 2d. This invention consists in the construction and use of what the inventor calls an "anti-induction diaphragm" between the end of the telephone magnet and the metallic diaphragm at present in use in the instruments employed for telephonic communication, the object of the invention being to decrease the induction and thus to prevent the sound or voices from other wires being heard by the operator. The "anti-induction diaphragm" consists of a disc or discs of paper, parchment, papier maché, or other suitable material (of a smaller diameter than the ordinary metallic diaphragm) placed between the latter and the end of the telephone magnet. (*Provisional only.*)

5316. "Apparatus for lighting railway carriages, &c., by electricity." R. LAYBOURNE. Dated December 5. 6d. Relates to an improved arrangement and combination of apparatus employed for lighting railway and other carriages and trains by electricity. For this purpose the inventor mounts or affixes a dynamo-electric machine so that it may be driven by the wheels or axles of the engine, tender, or carriage of a train or other vehicle by means of bands or straps and pulleys, or by toothed wheels, or by friction pulleys actuated by the tyres of the wheels, or by other motive power carried thereon, the current of electricity derived from such dynamo-electric machine being employed to charge or maintain the force of a series of Faure's accumulator batteries (or any other suitable accumulator capable of storing electricity), such accumulator being carried by the train or carriage.

5322. "Electric accumulators." J. IMRAY. (A communication from abroad by Jules Carpentier and Dr. Oscar de Pezzer, both of Paris.) Dated December 6. 2d. In electric accumulators in which equal surfaces of lead are employed the negative plate has formed on it a suboxide such as Pb^2O and when this plate is fully oxidised there still remains on the positive plate a peroxide such as PbO^2 unreduced, and consequently useless. In order to lighten and simplify the accumulator its plates are, according to this invention, so proportioned in thickness and surface that useless material is avoided and more complete and uniform action is insured. For this purpose the negative plate, is made very thin and the positive plate has about twice the thickness and about half the surface area of the negative plate. Each plate, instead of being made in one piece, consists of a number of blades bent double and placed side by side within a porous cell of retangular shape, all the blades of a cell being soldered to a conducting wire or bar at the top. (*Provisional only.*)

5338. "Secondary batteries." DESMOND GERALD FITZGERALD, C. H. W. BIGGS and W. W. BEAUMONT. Dated December 6. 6d. Relates to the production of the plates or electrodes employed in secondary batteries. It is necessary that these plates should expose large surface to contact with the electrolyte, as for instance by being made porous or by multiple folding. One part of the invention consists in making these plates by drawing sheets of lead between two flat surfaces of wood or metal, one of which would have a reciprocating motion of small range, and be provided with a number of fixed points, such as pin or needle points, disposed in such a manner as to finely perforate the sheet of lead which would de drawn at the necessary speed between the two surfaces, so that the perforations should be closely contiguous. The points or punches may be disposed so as to occupy intersecting points made by lines drawn parallel to each other, and traversed by other parallel lines at a certain angle thereto. After perforation these plates are oxidised or chemically treated, so as to prevent metallic union when being mechanically manipulated, as herein further set forth. With this in view the inventors prefer to immerse the perforated plates in dilute sulphuric acid contained in a vessel from which air may be withdrawn, the object of this being to fill the perforations with a fluid capable of acting superficially upon the metal, so as to produce for instance a coating of lead sulphate within the perforations.

5360. "Telephone transmitters." E. H. JOHNSON. Dated December 7. 2d. According to this invention the inventor uses an electrode made from a metal of high specific resistance, such as tellurium, boron, or silicon in combination with a diaphragm, the primary wires of an induction coil and a cell of battery or other source of electric energy, which combination constitutes a telephone transmitter, possessing certain important and valuable advantages over other telephone transmitters. The inventor has found by experiment that when the metal used forms part of a low resistance circuit, a slight variation of pressure between it and an electrode of similar or dissimilar metal will produce a corresponding variation of the resistance of the circuit, and consequently a variable strength of electric energy sufficient to actuate the diaphragm of a telephone receiver, and that a variation quite sufficient for the purpose of transmission of speech so as to render it distinctly audible in the receiver may be had without producing an actual break of the circuit by a separation of the electrodes.

5385. "Telephones, &c." G. W. FOSTER. Dated December 9. 6d. Consists of a telephone handle or case furnished with an exterior groove or recess for the reception of a helix or coil, also with a hole for the reception of a magnet, and two holes bored at an angle for the reception of telephone cords. Also of a permanent magnet fashioned with a screw cut head and a fixed metallic screw cut adjustment collar, whereby said magnet can be fixed and adjusted to its proper position with reference to the diaphragm of a telephone. Also of a combined lightning arrester and binding post device, consisting of two or more metallic pieces arranged in a ring shape provided with threaded connections for holding the contact points of telephone cords, and suitably connected with the ends of the telephone or other helix, said metallic pieces being fashioned with teeth or corrugations on their surfaces and placed near to one another. Also of a telephone constructed of two metallic plates, each fashioned with a contact shoulder for receiving a diaphragm, and placed shoulder to shoulder for holding the diaphragm and forming an air chamber, said diaphragm being insulated from either or both of the plates, and said plates being provided with hinges and made to form a door or cover to a receptacle for holding an induction coil or other matters. The plates being used as conductors of electricity and to complete the primary circuit of the telephone. Also of a telephone transmitter consisting of a spiral spring fastened to a diaphragm at one end and a pin at the other, in combination with a suitable electrode held in a cap supported by a pressure spring, said spring being attached to an insulator by a screw at one end and to the cap at the other by a screw nut, together with a screw for governing the pressure of the electrode against the pin. Lastly, of the insulator for insulating the primary conducting wire from the inner metallic plate.

CITY NOTES.

OLD BROAD STREET.

SOUTH AFRICAN BRUSH ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

ON Monday last the first ordinary general meeting of the above company was held in Cannon Street Hotel, which was preceded by an extraordinary general meeting, held for the purpose of confirming a special resolution passed at a previous meeting of the company on June 19th last. Colonel George Coxon, chairman of the company, presided.

The secretary, Mr. Thomas J. Seel, having read the notice convening the meeting, the resolution, which was as follows, was taken as read:—

"That the articles of association be altered in manner following, that is to say:—

"The following article shall be substituted for article 71, viz.:—

"71.—The office of director shall be vacated—

"(1) If he become bankrupt, or liquidating debtor, or lunatic, or compound with his creditors.

"(2) If he ceases to hold the requisite share qualification.

"(3) If he absents himself from the meetings of the board, without leave of the board, for a period of three consecutive months at any time.

"Any director (whether an ordinary director or a managing director) who otherwise than as a member or director of an incorporated company, is concerned in or participates in the profits of any contract or transaction with the company, or is entitled to any interest in any property about to be purchased or taken on lease by the company, shall at or before the time when such contract, purchase, or transaction shall be entered into or agreed to on behalf of the company, disclose the nature and extent of his interest in any such intended contract, transaction, or property, and thereupon a memorandum to that effect shall be entered in the directors' minute book. In default of such disclosure being duly made when and as required (but not otherwise) a director shall be held to be a trustee for the company to the extent of any profit or emolument he may have or obtain under or by reason of any such contract or transaction, or by reason of any such purchase or lease, and if such director be the sole person interested in such contract or transaction, or in the property purchased, or taken on lease, the contract or transaction, or purchase, or lease may be set aside at the option of the company. A director who is concerned in or participates in the profits of any such contract or transaction, shall not vote in respect thereof, notwithstanding that his interest is merely that of a member or director of an incorporated company, or that he has duly declared his interest, and if he does so vote, his vote shall not be counted."

The Chairman stated that the sole object of the extraordinary meeting was to confirm the above resolution, and moved its confirmation in the usual terms.

Mr. C. E. Atkinson seconded the motion, which was put to the meeting and carried unanimously.

The Chairman: Gentlemen, that finishes the business of the extraordinary meeting. The second paragraph of your notice is with reference to the first general meeting of the company which I have now the honour to open. On the last occasion when we met there were certain queries put to us—rather prematurely we thought, considering the company was only just started—and we intimated that on this occasion we would be more prepared and ready to give any information with regard to the position, progress, operations, and prospects of the company than we were then prepared to do. In pursuance of that engagement, I will, with your permission, read you a few notes which I have made on the position of our company, because we consider ourselves, as representatives of the shareholders of this company, as custodians of their interests, and that therefore we hold we ought to have everything in common with them, and to retain nothing from them with which they should be made acquainted. Of course there are certain matters with regard to terms of contracts that you will understand, as men of business, it would be absurd to expect to be published; that it should not be published to the whole world any more than that any one of you in business would think it wise to publish his terms of contracts to the world. But any shareholder who wishes full information can have access to the books at any time, and Mr. Seel, our secretary, will be always glad to give any information to any shareholder who may wish for it. This company was registered on May 13th last, and it will be no doubt satisfactory to you if I say a few words with regard to its position and prospects. The shareholders will remember that in 1881 Messrs. Blane and Macdonald acquired from the Anglo-American Brush Electric Corporation, Limited, a licence to use in South Africa the Brush system of electric lighting. They sent to the Cape Mr. Donald Macdonald, now our Colonial manager, and also purchased and forwarded to South Africa some engines, dynamo machines, and plant. The company acquired from them not only the concession for the use of the Brush system, but also the plant in the colony and in transit and the benefit of the contracts under negotiations which had been opened or were in course of being arranged. The shareholders will be aware that a company starting new business such as ours will necessarily have to spend money in experiment and in temporary installations; and the negotiations which had made most progress at the time of the company's incorporation related to the lighting of Kimberley. So long ago as October last our manager reported that since his arrival he had seen several members of the Town Council on the subject of lighting the town, and from what had transpired there was every prospect of securing a good contract. From time to time he reported the progress made in the negotiations for the contract, and in January last he reported that he trusted soon to be able to state that a contract had been secured. I give you, gentlemen, merely extracts from his letters bearing upon this point, and all the extracts that I shall read are simply those that bear upon that point. The others refer to the general business of the company. In February he reported that experimental lights had been started, that is, in Kimberley, and that he was pushing on the final arrangements with the council. On the 2nd of March he reported that the lights had been going on steadily, and they had given general satisfaction, and he goes on to say that he was negotiating for their permanent installation, and that the difficulty—I beg to call your attention to this—which stood in the way of making the contract was that the lighting rate was not to exceed 1d. in the £, which was not sufficient to produce enough to provide sufficient remuneration for installing and working thirty-two lamps required to light the town. And it is an important fact that at that meeting an addition of £3,000 was made to the rates for the purpose of increasing the funds in hand for the lighting rate. That is, an additional £3,000 raised by the corporation with a view to lighting the town with electric light. The whole thing may have to be submitted again to the ratepayers. Later on in the same month Mr. Macdonald informed us that a meeting of ratepayers would immediately be called, and that he thought his final proposal would be accepted. On the 11th of May, two days before the company was registered, a telegram was received here; it ran as follows:—"Have made a contract for Kimberley." It was, therefore, very gratifying to the directors to be able to announce in their prospectus that a telegram had been received; that is, that the contract had been completed with the Mayor of the town of Kimberley to light the town with the Brush system on terms which the directors believed would prove highly remunerative. Our manager communicated to the directors the rate of the proposed contract as agreed to by the Town Council. The directors did not consider it would be advisable in the interests of the company to make public the terms of this contract. But they consider them satisfactory in all respects, and negotiations are still going on with every prospect of ultimate success. With reference to the Kimberley contract, the directors have to add that, although it has been approved, and the resolution to seal it signed by the Town Council, a minority of the ratepayers (the majority have voted in its favour), interested from other motives, are still endeavouring to prevent its being carried into effect, and have gone so far as to commence proceedings to restrain the council; that is, to restrain the Town Council, in the person of their mayor, from signing the contract, on the ground that the corporation, as at present constituted, is not a legal body because the voters' list for the present year has not been made up. With reference to this hitch our manager writes: "I am in no way anxious as to the result; but some further delay will be involved, as in all important cases appeal is made from the High Court of Griqualand West to the Supreme Court of Cape Town; and in the meantime the work has been proceeded with." New plant is on the way, and the work is being pushed on in order to complete the contract. The directors cannot but think that the public feeling in Kimberley will be too strong for the opposition, and that matters will go forward presently more smoothly than at present. Concurrently with these negotiations our manager, to whose zeal, untiring energy, and great ability, we hope one day to point as the chief factor in the success of the company, had been negotiating for the lighting of the Cape Town docks, harbour, and railway station, and has, we are happy to report, brought his negotiations to a successful issue. On May 2nd he writes with reference to the experimental installation in the Cape Town docks, the lamps have worked perfectly since I wrote on the 6th ult., and without interruption, "and that it was probable that he would be asked to submit an estimate for lighting the outskirts of the town," where the gas company, whose contract has been continued for another year, has refused to lay their mains, owing to the small number of lights required. On May 30 he wrote:—"Lights in the dock are giving every satisfaction, and I have reason to believe that they will be permanently established." Further on he adds: "Lights are working well in the dock over thirteen hours per night," but the Board have yet come to no decision. The engineer informs me that the only hesitation on the part of the commissioners is their want of perfect assurance that the Brush system is the best; but he has been able to satisfy them that it is the cheapest. That, I may say, is the government engineer, not our representative; and I think there is little doubt the light will be adopted. He adds: "The new company should, I think, work up incandescent lighting for uses which would open a larger field for lighting in all interior towns where gas is beyond reach. On the 9th of June he wrote that if the Kimberley mining board did not undertake the lighting of the mines, the company will certainly light their own works; and that it is from this source that he anticipates our chief business from the fields; but owing to the extreme depression now prevailing it may take some time to develop this branch of our business. Again he writes: "You will see from the copy of the *Port Elizabeth Herald* that permission has been obtained from the Town Council of the town to exhibit a set of lamps in the streets. Not very long ago the Port Elizabeth Council refused to have anything to say to the light—I suppose they like the look of it." In the same letter he intimates that he has addressed letters to the Government and Table Bay Harbour Board, stating that it is the intention of this company to establish in Cape Town a general electric business, and that they are prepared to enter into contracts for lights at fixed rates per light per annum, to be worked by our own men and at our own risk. On the 4th of this month we received the following satisfactory telegram, which comes well after these negotiations by our manager:—"Dock Railway agreed; sail to-day;" which points to the final conclusion with the dock and railway. "Sail to-day" means this: We thought as soon as our company was formed that there were a good many matters that could better be discussed personally with our manager—whose very extensive experience and knowledge of all the fields of future operations in the Cape are quite of exceptional value—that his presence here would be more satisfactory and would enable us to see our bearings a little better. Our manager spoke in one of the letters which I have read of the necessity of incandescent lighting. I refer back to that to explain this telegram, because, with reference to the extract of the letter of May 23rd, prior to the formation of this company, Mr. Alexander Macdonald, of Blane, Macdonald, and Company, had been granted the refusal of the patents for South Africa held by the Electric Storage and Force Company—the Sellon-Volckmar accumulator—on exceptionally favourable terms. I may add, what may not be generally known, that we may now say the Sellon-Volckmar and Faure accumulator, because this company has absorbed the patents of Mr. Faure as well as the well-known patents of Sellon and Volckmar. In fact, they cover now all the patents that can be applicable to what we may look upon as the groundwork of all future electrical operations. Our agent alludes to the question of lighting solely; but I need not tell you that the facilities for lighting given by this valuable accumulator are only a small part—certainly only a part—of the immense power and advantages we shall possess by holding this patent, in the matter of tramcars and force for machinery, in fact, force as well as light. The directors were enabled, through the good offices of Mr. Alexander Macdonald, to open negotiations with the Electric Storage Company, which resulted in acquiring these patents on the same favourable terms. They are exceptionally favourable, and we are very fortunate to be in the position to be able to tell you that we are, in so far as that goes, holders of exclusive rights of the Brush system and of the Sellon-Volckmar accumulator system, and so far, are masters of the situation. One matter in the course of ordinary business, and the only one that calls for our attention, is the confirmation of the appointment of Messrs. Deloitte and Dever as auditors of the company, which, therefore, I beg to propose.

Mr. Lloyd seconded the motion, which was carried unanimously.

The Chairman: That completes then our business at this meeting, and I am very much obliged for your attendance.

In reply to a shareholder, who asked whether it was the intention of the company to apply for a Stock Exchange quotation,

The Chairman said they had applied. They could not possibly get a quotation till this clause of the Articles of Association were altered, and it was in order to qualify them for this quotation that an extraordinary meeting had been called to-day.

On the motion of Mr. Edmund Hornsby, seconded by Mr. Dickson, a vote of thanks to the Chairman was carried by acclamation, to which the Chairman briefly responded, and the proceedings terminated.

THE ELECTRIC LIGHT AND POWER GENERATOR COMPANY, LIMITED.

An extraordinary general meeting of the shareholders of the above company was held on Friday, the 14th inst., at the company's offices, 47, Cannon Street, Admiral E. A. Inglefield presiding.

The secretary, Mr. F. H. Landon, read the notice convening the

meeting, which stated that the purpose of the meeting was to confirm the following special resolution which was duly passed at an extraordinary general meeting of the members of the company held on the 27th ultimo: "That the name of the company be changed to 'The Maxim-Weston Electric Company, Limited.'"

The Chairman said: That, gentlemen, is all the business before us to-day. Some little misapprehension, however, has arisen with regard to a paragraph, as printed, of my speech at the general meeting of the company, and I think this a favourable opportunity—I won't say of qualifying, but of explaining what I then said. I told you we were in negotiation for selling concessions to a very large amount, that we were also engaged about some very favourable contracts which we were very hopeful would yield large profits. I should like to qualify it by saying that it should be stated that the contracts are not quite independent in themselves; they were dependent upon one of the concessions in progress of negotiation, which he had previously mentioned. If the contracts, as well as the concessions, were completed, the contracts would be made over to the concessionaires under certain terms. If the concession were not carried out and the contracts were, the latter would be worked by this company on profitable terms. I think this misunderstanding it is desirable to correct. It is no actual alteration of the facts—but it must be understood that the contracts must be looked to first and the concessions afterwards; for if none of the concessions were carried the contracts could be worked, though, of course, in one case the profits of the company would be larger than in the other.

Mr. Russell asked what proceedings would be taken to make it clear that under the new name the company would still be the same?

The Chairman said that in contracts, and so on, the new name would be employed with the old name in brackets, so that there might be no misunderstanding. They required, he might add, permission from the Board of Trade before the shares could be issued under the new title. They expected that to be done within a fortnight. The Chairman, continuing, stated that they had at the Reading show, which was then taking place, an exhibition of their system, which was visited by 20,000 people. He might also read to the meeting, from a paper read by Mr. Sugg before the Gas Institute in June last, the following comparison of lights from tests made:—Jablochkoff system, 114 candles; Brush, 557; Weston, 1,466. To this latter figure the author added, "This is the most powerful light I have yet tested."

Colonel Gilbey said that statements had been made that the Brush was the cheapest system, but when they took into consideration the fact that this company's system supplied such a much greater illuminating power, they could claim economy as well as efficiency. He believed that wherever their lights were shown they extinguished everything else.

The Chairman said that that was all their business. He might just add that companies such as theirs were not to be judged by the market price of the shares. With all these mushroom companies—for he could not but think that many of them were mushroom companies—starting up around them, he could easily understand that people were a little perplexed as to what was to be the light of the future. He thought that their light would stand the test of any comparison. At Reading, where their exhibition took place, he believed that another company's exhibits—he would not mention its name—were quite thrown into the shade by the Weston lights.

In reply to Mr. Griffiths, the Chairman said that the new title would be impressed in the articles of association, and upon their prospectuses wherever their name occurred.

A vote of thanks to the Chairman was moved by Mr. G. Russell, seconded by Mr. Griffiths, and carried unanimously, and the proceedings then terminated.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

A SPECIAL meeting of the above company was held on Tuesday last in the City Terminus Hotel, Cannon Street, Sir Henry Tyler, M.P., chairman of the company, presiding. The secretary read the notice convening the meeting, which stated that the following resolution would be proposed: "That the 85th of the Articles of Association be repealed, and that in lieu thereof the following be henceforth the 85th of such articles:—'85. The directors may, from time to time, of their own authority, pay to the members in proportion to the amounts paid up, or credited as paid up, on the shares held by them respectively, such bonus and such interim dividends as in the judgment of the directors the position of the corporation justifies.'"

The Chairman said: We have asked you, gentlemen, to be good enough to meet us here to-day in order to get us out of a little difficulty. That difficulty is rather a serious one, and, as far as I am aware, it is an unprecedented one. But the fact is we have a good deal of money now, and we wish to distribute it amongst you, and we are unfortunately precluded by our articles of association from so distributing it. Now these articles of association are, of course, our law; we are entirely bound by them, and, it is only on our personal responsibility that we can depart from them. The amount we wish to distribute amongst you we have arrived at this morning after looking through all the figures of the company, so far as we are able to make them out at the present time. You are aware that under the 91st article, on page 29 of the Articles of Association, the true financial statement of the corporation and general balance-sheet are to be made out as on the 31st December, so far as the business of the corporation will admit, and should be laid before each ordinary general meeting after the first general meeting. So far, you see, we can only make our accounts and have our ordinary general meeting once a year. We have not thought it at all worth while to go through the process of taking stock, as we would have to do in making up our accounts at the end of each year, but we have prepared a rough balance-sheet to satisfy ourselves as to the amount which it is desirable to distribute, if you are good enough to give us permission to do so, and in that way we have arrived at the sum of £245,000 that we have to pay to you whenever you like to receive it, and we propose, with your permission, that it shall be paid to you in the middle of August. In order to do that we must alter Article 85 of the Articles of Association which says, "That the directors may on their own authority once in every year pay to the members a sum on account of the dividends not exceeding a rate of 10 per cent. on their respective shares." It is quite clear that the legal gentleman who drew that article, as well as the directors who sit before you, had no idea when this company was incorporated what success it was likely to meet with. (Hear, hear.) And therefore we were precluded by that, and we precluded ourselves, from paying more in the way of interim dividends than 10 per cent. per annum on the respective shares. That I take to be the meaning of this clause. Having, as you will see, the sum of £245,000 to distribute at present amongst you—and that, I may say, is entirely out of the profits in this undertaking—we are obliged to ask you to allow us to alter this article of association, and we have done so, merely repeating what was said in the previous article, that the entire net profits of the corporation shall belong to the holders of the shares of the corporation—I think you will admit that this is sound doctrine—and shall be divided among all the shares of the capital of the corporation for the time being issued and fully paid up, or deemed and taken as fully paid up; and in case of any of the shares not being fully paid up, then in respect to such shares in proportion to the amount of all calls then paid on such shares. Now, you will see in the resolution we have put before you to-day and in the individual article which we propose to alter, we have carried out the proposal as prescribed in the 84th article which I have just read to you, and therefore our resolution to-day is "that the directors may from time to time, on their own authority, pay to the directors in proportion to the amounts paid up or credited to be paid up"—the very words of the previous article—"on the shares held by them respectively, such bonuses and such interim dividends as in the judgment of the directors the position of the corporation justifies." We consider after having looked through the figures this morning that our position justifies our dividing amongst you this sum of £245,000, and we therefore recommend you to pass this resolution in order to enable us to distribute it amongst you about the middle of August. I beg to move the resolution I have just read.

Mr. Sellon said: Gentlemen, I beg to second the resolution which our chairman has so well put before you. He has fully explained to you the reasons which make it desirable that this resolution should be carried, and therefore it is quite unnecessary that I should amplify upon those reasons. I simply beg to second the resolution, and I hope it will be your pleasure to accept it.

Mr. Isaac said that if he understood rightly, the money which it was proposed to divide amongst the shareholders as a bonus had arisen from the sale of licences which had been given to other companies. He would suggest that instead of distributing the money as bonus it should be put to account as capital. That would make no difference as to the amount to be divided, but it would as to the nature of the payment itself. He did not think but that the fully paid up shares, and those in which only £4 had been paid up, would eventually become of the same value, and that they would be able to divide their dividends without the use of any capital at all. But if they divided this money as a bonus, the fully paid up shares and those on which £4 had been paid up would remain always at the same relative value. He would, therefore, propose that the money proposed to be distributed as a bonus should be distributed *pro rat*â on capital.

The Chairman: Do you move that, because that is hardly in order as an amendment? This is merely a proposition for the rejection of certain words in the Articles of Association and the substitution of others. I have not asked liberty to divide any money at all.

Mr. Isaac said he would put it in this form: "That the proposed resolution be modified to this extent, 'The directors may from time to time, of their own authority, pay to the members, in proportion to the amounts paid up or credited as paid up on the shares held by them respectively, such return of capital (instead of "such bonus and such interim dividends") as in the judgment of the directors the position of the corporation justifies.'"

Mr. Abbott said that as no one had risen to second the amendment it was a true estimate of the opinion of this meeting to say that they quite agreed with the resolution proposed. He himself quite agreed with the proposal of the Board for this reason, that the mover of the amendment was under a decidedly wrong impression in supposing that this company parted with any valuable portion of its property through having granted licences or concessions either in any part of this country or abroad. In these concessions—he should be glad to be corrected if he was wrong—all that they had parted with was the licence to develop the Brush system in various parts of Europe. At the same time they formed a very valuable adjunct, seeing that the company manufactured all the material which these subsidiary companies employed, and they had therefore in them a very valuable outlet for the commodity in which they dealt without any increase in their capital. So far as he understood it they were establishing really a goodwill on a going business, and a profitable goodwill which would rather increase the value of the capital which remained; but in order to still further increase it, it was desirable to have as large an addition to the reserve fund as possible. This alone would give them the command of the market among the electric light companies. He looked with very considerable jealousy on a proposal that the capital already subscribed should be returned, when it was in this company so very profitably employed. It had been the fashion of various companies from time to time and at periods of great prosperity, to reduce their capital.

It was done in the case of the Telegraph Construction Company, a favourite company with him at the time. When a large sum of money was made, the directors wisely said, "This is exceptional;" and they wrote down their plant, machinery, and *goodwill*—let them mark that; and returned that money to the extent of £8 a share to the proprietors. But it seemed to him, that in the case of this company exactly the reverse had taken place. They had got an increase in the value of that goodwill, and therefore in common sense they could not possibly write it down. He therefore trusted that they would not be led away by such proposals as that made by the proprietary to-day. He commended the board for dividing £245,000 amongst the shareholders, presuming before they arrived at the figure that they had taken good care to make ample provision for the future, to write down the goodwill of the business, or rather the patent rights and the machinery, and so on, which were always deteriorating; but certainly there could be no justification for writing down the goodwill of a business which seemed to be steadily on the increase.

Mr. Stewart inquired whether the directors were justified in allowing a portion of the proprietors to pay the sum of £10 without giving the same option to all the proprietors, a great number of whom were only called upon to pay £4. If the answer was that there was no distinct justification for the step, he had an amendment to the original resolution to propose.

The Chairman: May I ask whether the speaker is an original proprietor, or not? because if he is, he would know the facts of the case. When we started this company in the first instance, nobody believed in its success, and not many were much inclined to put money into it at all; and when we issued the prospectus and asked for our capital we had some difficulty in getting what we wanted, and we did then invite all proprietors to pay up in full. We not only gave them the opportunity, but made the request to do so, and urged upon them to do it. Therefore every proprietor had then the opportunity of paying up his shares in full. But I should like to tell you the whole story. Some proprietors, believing in the success of this company, did so, and they held now £10 paid up shares. Then, again, one gentleman in particular, I remember, came to the secretary having shares on which £4 had been paid, and thinking that they would go to a premium, was anxious to give a little more. We had got at the time money we called for, but that one gentleman sent to our former secretary who, under some misunderstanding, allowed him, after the shares were at a premium to go on paying up. That came before the directors. They were obliged to honour the engagement of their secretary, but finding what had been done, they put a stop to the operation, and nobody after that was allowed to pay up so as to make his £4 into £10 paid up shares. These are the exact facts of the case.

Mr. Brooksbank said that the gentleman who proposed the amendment was quite out of order, because the Board had not the power to reduce capital. It was *ultra vires;* they could not do it. He rose to ask whether it was their intention to pay this bonus in a larger proportion to those gentlemen who had fully paid up shares than to those who had only paid £4 on their shares. It might not have been convenient for many gentlemen to pay up the money at the time the appeal from the Board was issued, and he thought it would be a case of great hardship if their case was not taken into consideration. Surely they would never propose to give a bonus of £10 to those who had paid their £10 on the shares, and only £4 to those who had paid only £4. Were they going to perpetuate that? He would put it to the sense of fairness on the part of the Board. It was under exceptional circumstances those £10 shares became so much more valuable, under circumstances which none could foresee. He left it confidently in the hands of the Board, feeling sure that strict justice would be done to the large body of the shareholders.

Mr. Henry Maudsley would like, if the chairman would inform the shareholders, to know what amount was placed to the reserve fund of this company.

The Chairman: Before coming into this room I told you we went into certain figures. Our object was not only to see what amount we could offer for distribution, but also what was left to represent the capital and the assets of the company, and in doing so we found there was a very large margin indeed representing the paid-up capital, and we ascertained what we had in hand and what we should retain after distributing this £245,000. We did so not so much on your account as on ours, because we said to ourselves, "We are not going to incur any liability in this matter." In asking the shareholders to receive what we had to divide as profits, we retain not only a large reserve fund, but a large margin beyond it. That is the position in which we come before you. With regard to what Mr. Brooksbank said, it is hardly an accidental circumstance whether a man subscribes £4 or £10 (hear, hear). It may depend upon the accident of how much money he has at that moment to put into the company, but that is the only accidental part about it. I think it was with great deliberation that the gentlemen would subscribe either £10 or £4, as they thought proper, when they were first offered the option of subscribing either the one or the other. It is our desire to do even justice to everybody. I should be sorry to wrong any man. One or two gentlemen representing holders of the £4 paid shares have spoken very nicely their opinions, but we have heard nothing from the £10 paid shareholders; for this reason I think that there is no proposal before us which would do them any injustice; I am quite sure, however, that if we gave the holders of the £4 paid shares a part of this distribution in a larger proportion than they had subscribed, we should have a tremendous outcry from the £10 holders; the only thing we could do was to alter the articles of association. Article 4 says distinctly that the entire net profits of the corporation should belong to the holders of the shares of the corporation for the time being issued, or fully paid up, or deemed and taken as fully paid up, and in respect of such shares in proportion to the amount of all calls then paid on such shares. Of course these articles were not drawn up with a view of this latter state of things, the gentlemen who drew them up never contemplated what has since happened. But here are the articles by which we are bound. We have no choice in the matter. We cannot offer a certain sum to the £10 holders and another to the £4, but we must pay every holder in proportion, and that really seems common sense, on the face of it, especially when everybody had the option to begin with of subscribing either £10 or £4. Therefore, since the amendment has not been seconded, I shall ask you to pass the resolution unanimously.

Mr. Isaac would wish it to be distinctly understood that he had never suggested that the larger proportion of the division should be given to the £4 paid shareholders than to the £10. He would not like it to go forth that he had done anything so unjust.

The Chairman said he had done it in an indirect manner. He would now put the resolution. He might mention that he had a large amount of proxies, but he was quite sure it would not be necessary to use them.

Mr. Brooksbank: I have not had a satisfactory——

The Chairman: You are quite out of order, sir.

Mr. Brooksbank: Then if I cannot obtain information I shall feel it my duty to demand a poll.

The Chairman then put the resolution to the meeting and declared it carried with two dissentients.

Mr. Brooksbank: You have not proved the articles of association infallible, because you have moved an amendment to them. I contend that it is most grossly unjust—(hisses)—that those gentlemen who have paid £10 simply should have a larger share of the dividend than the other shareholders.

The Chairman: That closes the business of the meeting.

On the motion of Mr. Maudsley the usual vote of thanks to the chairman was carried unanimously, to which the chairman briefly responded, and the proceedings terminated.

THE CUBA SUBMARINE TELEGRAPH COMPANY, LIMITED.

ON Wednesday, at the company's offices, 61, Old Broad Street, the twenty-second ordinary general meeting of the above company was held, Mr. Thomas Hughes, Q.C., Chairman of the company, presiding.

After the notice convening the meeting had been read by the secretary, Mr. James Scott,

The Chairman said: Next comes the report and accounts, and I suppose you will, as usual, take them as read. So I will at once move that the report and accounts as submitted to you be read and adopted. The shareholders will have seen from the report that the half-year has been the most successful that the company has ever seen since its establishment. It will be, no doubt, satisfactory to them, as it has been to the board. The traffic receipts, which is the best test, as compared with the traffic receipts for the corresponding half-year of 1881, show an increase of £3,000, or very nearly so. Now, in respect to the distribution, the shareholders will see that again the board have thought it wise to carry a very considerable sum to the reserve fund. They are all aware—the shareholders who have attended these meetings—that this has been the policy of the board from the very commencement of the company, and that the board will not feel themselves in a thoroughly satisfactory condition, until the reserve fund reaches £50,000. They will be pleased to see that that amount is being very nearly reached, for the reserve fund now stands at £47,000. Then the shareholders will concur with the board in thinking that under the circumstances the dividend on the ordinary shares might be increased to 8 per cent. (hear, hear), and that is the recommendation which we shall lay before you for your assent. I do not think there is any other subject upon which I need trouble the shareholders further. They will have seen by the accounts that the expenses are practically the same, in fact, some £200 less than in the corresponding period of last year, although the business of the company has increased so largely. With respect to the question of the dispute with the Spanish Government the shareholders will see that everything has been done to bring that to a conclusion, and we trust that the result of the appeal will be to put us in a position of getting a return of that fund. This meeting will presently be converted into an extraordinary meeting, generally to deal with the question of auditors. Without trespassing upon your time any further, I will move that the report and accounts be received and adopted.

Mr. A. F. Low: I beg to second that.

Mr. Thos. Greenwood: I think we should recognise our improved position more fully than you, in your modesty, Mr. Chairman, have been good enough to put it. I think we should congratulate the board upon their successful management and ourselves upon our improved position, resulting from that management. We are now in a better position, so far as I am aware, than we ever were before. The proprietors may probably put figures together for themselves, but I can state that the earnings for the half-year have been 15 per cent. per annum. We pay 8 per cent. on the ordinary shares; have added £1,700 to our balance; £3,950 to our reserve fund, equal to 7 per cent.; and during the half-year we have earned and paid what is equal on the whole year to 7 per cent., and we have carried forward another 2 per cent. for the half-year, equal to one per cent. for the year, besides adding to our reserve fund £7,000, which stood at the beginning of the year £40,000, and at the end £47,000, which is equal to a 30th part of the whole capital of the company. This satisfactory condition is not to be exceeded by any telegraph company in existence. The only thing that has struck me as singular is that the company should still be burdened by that 10 per cent. per annum upon preference shares. I do not complain of the terms upon which those shares were issued. But now we have improved our position so much, and are in addition to all I have stated, practically purchasing a new cable out of revenue, I think the time has arrived when we should consider whether it is not possible

to place ourselves in a better position with regard to preference shares. I think it would be worth while to consider the issue of £100,000 of 6 per cent. preference capital in £10 shares, and that those shares should be convertible into ordinary shares, within a limited period at option of the holders, and failing that they should be redeemable by the company at par; that for every share held by the preference shareholders they should be entitled to one ordinary share in the company, and a bonus in cash. Another mode would be to authorise the board to invest some of our reserve in the purchase of preference shares when the market is suitable.

Mr. Newton asked whether there was any prospect of a communication with the Western Brazilian, so as to increase their connection with Cuba; and he would also like to know whether the board had any information as to the threatened competition by Mr. Jay-Gould. With reference to the issue of capital to take the place of the existing 10 per cent. preference, he did not think it possible to alter the conditions of that issue. Mr. Greenwood had thrown out the idea that they could use the capital to purchase. They could not do that. The Court of Chancery would not sanction that. For his own part, he always had a grievance against the company, for when they received notice in half-penny wrappers they were put on one side, whereas if under a penny stamp would be taken notice of.

The Chairman: Well, gentlemen, with regard to the question that has been asked, so far as we are aware the Brazilian communication is not likely to be carried out; I trust it may be in the future; and of course, as Mr. Newton has said, whenever it is carried out it will be a source of great profit to this company undoubtedly. With reference to the other competition which was threatened some time back, so far as we are advised it is for the present entirely gone off. This is also satisfactory for this company. Now comes the only other question raised—the 10 per cent. preference shares. The last speaker has stated that it is out of the question that power should be obtained. It was suggested by Mr. Greenwood, as an alternative, to buy up those preference shares. He has stated that so confidently that there may be some recent decision in the Court of Chancery, of which I am unaware, which makes it qtite out of the question that such an alteration should be allowed in a company of this kind. We have no power at present, so to purchase the preference share I for my part believe it to be by far the best way of dealing with them. I think that to-day we should, seeing the feeling that exists amongst the shareholders, for every speaker has referred to it and placed it in the position which the board has, consider that very carefully, whether we cannot so modify the articles of association as to obtain power to invest our surplus capital in the purchase of those preference shares. I am not quite sanguine as to the result, but if not we must consider one of the other two ways which have been proposed to us. I now, therefore, simply beg to move the adoption of the report.

Mr. Griffiths said that some time since he was consulted by a tramway company, and that matter was taken before the Master of the Rolls, and he decided that the preference shares are a prior mortgage on the company. It was the case of Dent *v.* The London Tramways Company. They must deal with every shareholder individually.

Mr. Newton said that the West Indian and Panama had similar shares to this company, but they succeeded in doing what Mr. Greenwood had suggested. They were obliged to meet those who did not acquiesce, and these persons got all that they asked for.

The motion for the adoption of the report and a resolution that a dividend be declared at the rate of 10 per cent. on the preference shares and at the rate of 8 per cent. on the ordinary shares for the half year were then put and carried unanimously.

The Chairman then announced that Alexander F. Low, Esq., was a retiring director, and he now proposed his re-election.

Mr. Griffiths seconded.

The Chairman: With reference to the auditor, I think I need not say anything on this subject. This, however, I am bound to say: we have had a new eye upon the accounts, and I think I may say, that the impression of the board is that they have a very able and deeply interested auditor to control in future the accounts of the company, in Mr. Thos. Greenwood, who now retires and offers himself for re-election.

Mr. W. A. Hooper proposed the re-election of Mr. Greenwood.

Mr. Cochrane seconded.

Mr. Griffiths said this was an adjourned discussion of what took place three months ago. He did not want to create any dissension in this family (laughter). Mr. Cowan had left this transitory state of mundane affairs, and he would pay his tribute of respect to him as well as to Mr. Brand. The view he took at the last meeting with reference to the question before them was that it would be better for them to have two auditors instead of one, because good book keeping was necessary and exceedingly valuable, and secondly, because it would tend to raise their company in the estimation of the public. While he admitted that they were very prosperous at the present time, their past history shows that that was not always the case. The National Ocean Telegraph Company had had disputes with them, the West Indian and Panama Company had also had disputes with them, and that kind of thing must tend to loss of reputation with the public. He thought there was some reason why the public did not invest more in their shares, and why the market value was not equal to their intrinsic worth. The public must have some difficulty, however, in discerning what was good and what was bad. He did not think that anything which would increase their reputation with the public would be otherwise than wise and prudent. It was for that reason that he advocated that they should have two auditors instead of one; a single error might escape the one keen eye and be detected by the other keen eye. If they considered one auditor was sufficient guarantee, all well; but as a question of caution he thought it would be wise to incur a little additional expense that they might be sure themselves and make the public sure also.

The Chairman: The question before the shareholders is proposed and seconded, that Mr. Thomas Greenwood be the auditor of this company.

Mr. Greenwood said, as a copy of the report of this meeting would get into the hands of the absent shareholders, he should like to express to them and to the meeting his full appreciation of the reply to his circular which he sent to them. A very large proportion of the shareholders had been good enough to lodge proxies in relation to his re-election. Upon the question of the two auditors, he had only to say, that being committed by the circular to a certain line of duty, he was bound to fulfil it. Out of the many proxies with which he had been favoured, only twelve of the number had expressed views on the question of the two auditors; and of these, eight were in favour of two auditors, and four in favour of one. The question, however, must be put to the vote.

Mr. Newton asked what proportion these four votes bore to the number of circulars sent out. He had a strong opinion in favour of having two auditors.

The Chairman: The meeting is now converted into an extraordinary meeting, for the purpose of determining whether you will have two auditors. The proposal that will now be put before you will be that the present rule as to the electing of an auditor, in the event of a casual vacancy, be altered in the way you will see in the notice which has been distributed amongst you. We wish these words in Article 116 of the present regulations of the company cancelled—"If any casual vacancy occurs in the office of any auditor appointed by the company, the directors shall forthwith call an extraordinary general meeting for the purpose of supplying the same;" and the following substituted in the place thereof, "If any casual vacancy occurs in the office of auditor, the directors may appoint any shareholder or shareholders, or any accountant or firm of accountants, to audit the company's accounts, with such remuneration as the directors shall think proper, and at the next general meeting held after such vacancy the shareholders shall proceed to elect an auditor or auditors." We had to call an extraordinary general meeting a short time ago for the purpose of electing an auditor upon the death of Mr. Cowan. It was very common to place that resolution in the old articles of companies, but I think it would be a mistake to put it in articles drawn up at the present time. It must be most desirable not to have extraordinary meetings called simply for the purpose of supplying a casual vacancy in the auditorship.

Mr. Greenwood thought that it would be better, if the chairman had no objection, to continue the existing meeting and determine the question of a second auditor, and after determining that, and seeing whether the "Ayes" had it, then to proceed to the election of a second auditor.

Mr. Page: I second that.

The Solicitor: It has not been proposed yet.

Mr. Newton: Just to test the question I will move it.

Mr. Hooper remarked that one auditor had been sufficient for this company for the past twelve years, and he thought the proposal for a second seemed to indicate a want of confidence in the board of management, and in their new manager (no, no); that was the view he took of it. He therefore begged to move as an amendment, that one auditor was quite sufficient for such a small and simple statement of accounts as they had so clearly put before them from year to year. He did not think that the shareholders should use such language about confidence in the board as was generally done, and then on the first occasion that they had an opportunity of practically showing that confidence——

Mr. Newton: Mr. Chairman, I protest against that.

The Chairman: The shareholder has a right to express his views.

Mr. Cochrane would second the suggestion made, but on a totally different ground. He thought that it was better to put the responsibility on one man rather than to distribute it over others.

Mr. Newton had firmly expressed his opinion of confidence in the board, and had stated many times that the accounts were the clearest and most faithful of any telegraph company now before the public. He had not the slightest intention of raising any question of confidence in the board. He thought that was out of the question with a company paying 8 per cent. to its ordinary shareholders. The vote must be "Yes" or "No," for they could not put the amendment.

The Chairman: I do not consider the amendment irregular. Any shareholder has a right to put it in that form. The original proposition is that a second auditor be appointed.

Mr. Griffiths: In Parliamentary procedure a direct negative cannot be put as an amendment.

Mr. Greenwood: We shall not consider it an act of want of confidence in us if the shareholders have determined to have two auditors.

The amendment was then put, and the result was nine for and eight against.

Mr. Griffith repeated his previous remark that a direct negative was not an amendment.

Mr. Greenwood thought he should have some difficuly, because he could not record the proxies he held unless there were a poll.

The Chairman: The amendment is practically put as an original motion.

Mr. Hooper having withdrawn his amendment, hands were shown on the original motion—ten in favour and nine against.

Mr. Greenwood: I think I must demand a poll, but under compulsion.

A poll was then taken, when the numbers were for a second auditor, 28; against, 55.

The Chairman: That is taking the vote of the meeting without the board. The board, however, are of opinion that one auditor is sufficient.

Mr. Lindsay Scott (to the Chairman): Did you ever know of a board nominating an auditor?

The Chairman: Oh, yes; but in this case the suggestion came from the shareholders.

Mr. Newton could not see that much would be saved by the alteration.

Mr. Greenwood said he was present at the meeting when the suggestion for the proposed alteration of articles was made. Many of the shareholders were brought a long way to the meeting only six weeks before the half-yearly meeting six weeks later on. The shareholders then asked for the alteration: it was not for another body of shareholders to say whether they liked it or not. If a vacancy occurred, and they had only one auditor, and must have accounts presented, they must fill up the vacancy and put up with the inconvenience, or wait till the following meeting.

Mr. Lindsay Scott thought they did not need to alter an article to meet an emergency which might not occur once in fifty years. Mr. Greenwood looked like living many years yet (laughter).

Mr. Newton asked whether he would be irregular if he proposed an amendment that it was not necessary to alter the articles of association?

The Chairman said it was entirely their own question: the suggestion had come from the shareholders.

Mr. Griffiths thought that the expense of a second meeting to confirm the alterations, if agreed to, would be quite as great as calling a meeting to appoint a new auditor. The recent unfortunate necessity has only arisen once since the establishment of the company, twelve years ago. It seemed to him that it would be wise to leave things as they were.

Mr. Newton remarked that he thought the proposed alteration must fall to the ground.

There being no other remarks a unanimous vote of thanks to the Chairman was passed on the motion of Mr. Newton, and the proceedings terminated.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.

A HALF-YEARLY general meeting of this company was held on Tuesday last, 18th inst., at their offices, 38, Old Broad Street, Sir Daniel Gooch, Bart., M.P., Chairman of the company, presiding.

Mr. Shuter, the manager, having read the notice convening the meeting,

The Chairman said: Gentlemen, this is a meeting for the purpose of your asking questions rather than for any report from the board. We present no report or accounts, but I will state shortly the work which we have done during the past half year. We have manufactured about 1,000 miles of cable and laid about 550 miles of cable manufactured within the last year. We have also laid the German Union Cable between Emden and Valentia. That was completed in April by the *Scotia*. We have repaired the North Sea Cable, which is also now completed, and the *Kangaroo* has been twice to the Brazils to carry out the cable for the Western and Brazilian Company, and to repair the Brazilian submarine portions of the cable near Pernambuco. The *Scotia* has now been out about two months in the Atlantic repairing the Brest and St. Pierre Cable for the Anglo-American Company, and she recovered the cable in 1,940 fathoms of water in the Atlantic, and repaired that and put in 60 miles of new cable. She then went to repair the fault that has been for some time existing in the cable near Brest. That she is now engaged in doing. She has recovered the ends and buoyed them; but the weather has been so bad that she has not been able to put in the new piece. However, we hope that that will be completed as soon as we get two or three days of fine, calm weather. She will then go to the mid-Atlantic again to do some more repairs which are necessary there. It is a great thing to do to lift a cable which has been down twelve years in the mid-Atlantic, to repair it, and to put in a new piece, and to restore the cable. The cable taken out was in very fair condition—in fact, very good condition considering the length of time it had been down. But there were traces of defects which had taken place at short intervals of the cable from some chemical, no doubt, at the bottom of the sea. It does not continue far, but it is quite sufficient to create a weak point in the cable. We thought it almost more than we could expect to recover that cable and to repair it at such a depth of water after it had been down for such a long period. We are endeavouring to keep our works going by doing all we can to secure cable work. Having told you practically what we are doing I am afraid I have nothing to tell you as to the future. We are, of course, negotiating for work, and I hope that we shall be able to continue as we have hitherto done. I should be glad to answer any questions that any gentleman is inclined to put.

Mr. Ealing said: Is the 700 miles you have now of government contract work to be done in a hurry?

The Chairman: I do not know what you refer to.

Mr. Ealing: I only heard that, and I ask you the question.

The Chairman: We have not got a government contract.

Mr. Ealing: You had one.

The Chairman: We did have a contract. We have laid a cable of 900 miles in the middle of the half-year. Has any other shareholder any question to ask? There is no resolution to put. If there is no other question to ask I must declare the meeting at an end.

A vote of thanks to the Chairman for his conduct in the chair was then moved and seconded by two of the shareholders present, and carried unanimously. The Chairman shortly thanked the meeting for their confidence, and the proceedings terminated.

THE INDIA-RUBBER, GUTTA-PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED.—We are informed that the business of the Company for the past half-year has been satisfactory, and that the directors will, at the ensuing meeting, recommend the distribution of an interim dividend of 5 per cent., or 10s. per share, free of income-vable on the 26th instant.

THE DIRECT UNITED STATES CABLE COMPANY, LIMITED.—At a meeting of the board, it has been resolved to recommend a final dividend of five shillings per share (free of income-tax), such dividend to be payable on and after the 16th August next, making, with the interim dividends already paid, five per cent. for the year ending 30th June last, carrying forward £232 16s. 8d., after having carried to the reserve fund £9,531 9s. 1d., making it up to £264,000.

OFFICIAL QUOTATION has been granted to the Pilsen, Joel, and General Electric Light Company, Limited."

APPLICATION FOR SETTLING DAY AND QUOTATION has been made to the Stock Exchange Committee on behalf of the "British Insulite Company, Limited."

THE UNITED TELEPHONE COMPANY.—The directors have decided to recommend, at the meeting to be held on the 1st. prox., a dividend of 5 per cent. on the share capital, subject to audit.

THE BRUSH ELECTRIC LIGHT AND POWER COMPANY OF SCOTLAND (LIMITED).—The directors have appointed Mr. F. M. Brockelbank as secretary to the company.

TRAFFIC RECEIPTS.

West Coast of America Telegraph Company. The gross earnings, traffics and steamer, for the month ending June 30th, 1882, were £3,425, against £3,40[illegible] in the corresponding period of last year.

Western and Brazilian Telegraph Company, Limited. The traffic receipts for the week ending July 7th were £1,719, after deducting the "fifteenth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited.

THE TELEGRAPHIC JOURNAL AND

Electrical Review.

VOL. XI.—No. 244.

THE ELECTRIC LIGHTING BILL.

THIS has formed the subject of a long and carefully worded letter from the pen of Sir Frederick Bramwell, published in the columns of the *Times* on Friday, the 21st inst. It was followed the next day by another epistle on the same matter, and bearing the signature of Robert Hammond, the well-known originator of the Hammond Electric Light Company. Both these communications are well worthy the serious consideration of all interested in the future prospects of the electric light, and we need scarcely say that the arguments of both gentlemen are entitled to careful thought.

In speaking of the compulsory sale of electric light undertakings at the end of fifteen years Sir Frederick says :—

> The Electric Bill, by clause N of section 14, provides that where the lighting is done by an individual or by a private company, under a provisional order confirmed by an Act of Parliament, then at the end of fifteen years the local authority of the district lighted shall be entitled to say that it desires to purchase the undertaking, and thereupon the undertakers shall be compelled to sell. This in itself would be a sufficiently hard provision were the terms of payment fair; but the terms of payment are most unfair, for the arbitrator who, failing agreement, is to fix them is forbidden to take into account in so doing either past profits, goodwill (which means present profits), future profits, or any allowance for compulsory sale, and, having been thus told what he is not to allow, he is directed to ascertain the then value of the land, buildings, machinery, and plant, having regard to their suitability for the purposes for which they are intended; and this is to be the sole payment for the acquisition of the undertaking. Further, if the local authority should not choose to exercise this option at the end of fifteen years, then at each recurring period of five years the same option is to re-arise.
>
> As I have said, there is nothing in the nature of electric lighting to justify exceptional harshness; on the contrary, it is regarded with approval, and thus, if there be any exceptions, it is to be supposed they would be exceptions in favour of this useful, desirable, but undeveloped industry. I fear the obvious conclusion to be drawn from the foregoing considerations is that in all future applications to Parliament for a Bill to light a town with gas, or to supply it with water, or to make a new railway from A to B, there will, in the interests of consistency, be inserted provisions that at the end of the fifteen years the local authority may buy the gas undertaking at the then value of the fifteen years' old pipes and fifteen years' old works, that it is to get the waterworks on similar terms, while the railway, extending over the districts of many local authorities, will be doomed to be acquired by the Government for the then value of the land, works, rails, and rolling-stock.

Sir Frederick makes out a very dismal prospect for the future development of any enterprise, but we scarcely think he is justified in comparing established undertakings such as waterworks or railways, the details of which are all known beforehand, with a practically undeveloped (as the writer admits) industry like the electric light. It is evident that Mr. Chamberlain had the public weal very much at heart when framing the clauses of his Bill.

Electric lighting has made vast progress of late years, but in an intermittent and partially unsatisfactory manner as far as the general public is concerned, for it is still a most difficult matter to get at the truth of the question of cost, as any report on the subject generally leaves something unmentioned, and the opponents of the electric light have generally managed to get hold of some weak point in the arguments of its adherents. It is the general vagueness existing on this point of relative economy between the electric and other methods of illumination, and also the unscrupulous way in which much of the electric light business has been carried out, which probably induced Mr. Chamberlain to frame his Bill, so that electric lighting companies shall not receive more than fair returns for work done. We do not think that Sir Frederick Bramwell need fear that private enterprise in this country will be discouraged, and such undertakings pass into the hands of governing bodies. As a matter of fact, we need only mention the telephone, with which Sir Frederick has had so much to do. Instead of being monopolised the telephone industry has just been thrown open to all comers with certain restrictions, which we cannot imagine will be of a very severe nature. We believe with Sir Frederick that the making of governing bodies (generally) is a mistake, but surely we may rely on the good sense of Parliament to know where the line must be drawn. In the latter portion of his letter, the writer states :—

> At the end of 15, 20, 25, and every period of five years after the 15, the local authority watches to see if there is a profit, and if there be, then it comes in and buys, not upon the profit, but upon the materials. If there is no profit, so that it would not be worth while to buy the materials in order to earn the income, then there is no obligation on the local authority to buy at all, and thus in effect the Bill says, "As long as there is no profit or a poor profit, you, the undertakers, may continue to work, but the instant you get anything like an adequate return, then we will come and buy you up at a price which must inevitably be a comparatively small fraction of the capital you have laid out in the undertaking." I feel compelled to repeat that which I told the committee, "This is a monstrous proposal."
>
> It is on the foregoing grounds, I say, that the passing of this Bill must be looked upon as the beginning of the end of the carrying out of public enterprises by means of private capital.

This matter of profit or no profit depends almost entirely upon the management of the directorate of a company, and we do not see the force of Sir Frederick's argument that "as long as there is no profit, or a poor profit, you, the undertakers, may continue to work." We can quite understand the local authority as being anxious to buy a profitless concern at the end of a definite period, for the simple reason that under new management the undertaking might be made to yield a very fair return. Sir Frederick must know as well as any person in existence that the question of profit or no profit is usually a question of management. We have only to call his attention to a leading electric light company as an example of this. Others, probably, have electrical apparatus of as good, if not superior, nature, but that is not of much avail if the smartness of the directorate is absent. Mr. Hammond, who corroborates all the views expressed by Sir Frederick Bramwell, in one portion of his letter says :—

> In erecting electrical apparatus in a town, a very large proportion of the outlay will be for labour in laying the mains, erecting the posts, fixing the wires, putting in the foundations, and making the connections with houses on the route. Now, if at the end of fifteen years, when the plant is turned over to the local authority, no value is to be placed upon this very important portion of the first outlay, then consumers, during the term allotted to the electric light company, must annually bear their proportion of these dead expenses; and it is therefore evident that unless the electric light company has a long term, I should say at least twenty-one years, the proportion of the dead expenses annually will be so heavy that the consumers would find the price charged for the electric light too onerous. If however the suggestion of Sir Frederick Bramwell were adopted, and the plant at the end of the term allowed to the electric light company were taken over upon its value as a going concern, then all the dead

expenses forming such a large proportion of the original outlay would be paid for by the local authority taking over the business, and would be quite fairly charged to them, since they would be forced to spend a like amount if they started *de novo* in their town.

Looking at the matter purely from a commercial point of view, being the one which my managing directorship of an electric light company daily presses upon me, I should say that the Bill with its present purchase clause is not sufficiently tempting to induce capitalists to put money largely into companies contemplated by the Act.

They will feel that the early consumers, though willing if necessary to pay more than the price of gas for the manifest advantages connected with the electric light, could not be fairly asked to bear the dead expenses which should always be considered as part of the capital, and not charged to revenue.

If, on the other hand, the clause is amended so that the local authority which elects to purchase pays for the electrical apparatus upon its value as a going concern, then an immense stride will have been made towards admitting the public to participate in the boon, as the result would be an immediate setting on foot of undertakings to supply the electric current from house to house.

In the meantime we cordially agree with both gentlemen that there is ample work and to spare of an isolated nature for all the electric light companies at present established; but that Sir Frederick Bramwell's forebodings that the passing of this Bill means the beginning of the end in carrying out public enterprises with private capital are ill founded we feel convinced. He is right in believing that private enterprise has made England what she is, and we should be sorry to think that this will not be still more developed in the immediate future.

THE CHEMISTRY OF THE PLANTÉ AND FAURE CELL.

[On pages 21 and 211 of vol. X. of the ELECTRICAL REVIEW we reprinted, from the columns of our esteemed contemporary *Nature*, two interesting and valuable articles bearing on the above subject. These were written by Drs. Gladstone and Tribe, and we now republish a third paper by these two gentlemen, for which we are again indebted to the same journal.]

PART III.—*The Discharge of the Cell.*

THE two plates of a Planté or Faure battery consist essentially of lead peroxide as the negative element, and metallic lead in a spongy condition as the positive. These are brought into communication with one another through the lead plates which support them, together with the connecting wire.

The lead peroxide reacts both with the lead plate that supports it, and with the lead on the opposite plate. At first sight, it might be expected that the reaction between it and the supporting plate would be the greater, as the space between them is so small, and the resistance of the intervening liquid in consequence almost inappreciable. The action is, indeed, probably greater at the first moment, but, as explained in our first paper, sulphate of lead is immediately produced, and that which lies at or near the points of junction forms no doubt a serious obstacle to further local action and admits of the lead on the opposite plate coming more fully into play.

If we consider *à priori* what is likely to be the reaction between lead peroxide and lead, with water as the connecting fluid, we should expect :—

$$PbO_2 \mid H_2O \mid H_2O \mid Pb = PbO \mid H_2O \mid PbH_2O_2.$$

On experiment this is found to be actually the case, yellow oxide appearing on the negative plate, and white hydrate on the positive.

If, however, the reaction takes place in presence of dilute sulphuric acid, the result will inevitably be sulphate on both sides, for even if oxide be first formed, it will be attacked by that acid. Of course this production of lead sulphate on [illegible]ide might be expected gradually to produce a perfect [illegible]cal equilibrium. This, in fact, does take place under certain circumstances, but not under others. The reaction on the negative plate is always of this character, as far as our analyses have shown. We have invariably found the deposit to consist of sulphate of lead mixed with unaltered peroxide. If, however, the cell be allowed to discharge itself rapidly the lead on the positive plate is converted, not only into the sulphate, but, very partially, into lead peroxide. This is sometimes evident to the eye from the puce colour of the superficial layer, and we found also that this was confirmed by several chemical tests.

It is difficult to conceive how the reduction of the peroxide of lead on the one plate to oxide or sulphate should be attended by a direct oxidation of lead on the other plate up to peroxide itself, as that would involve a reversal of the electromotive force. It is more easy to imagine that the peroxide results from the oxidation of sulphate of lead already formed, through the agency of electrolytic oxygen.

When this peroxide is formed on the positive plate, it is not difficult to foresee what must happen. A state of electrical equilibrium will be approached before the peroxide of lead on the negative plate is exhausted. But the two sides are in very different positions with regard to local action. On the negative plate, the peroxide being mixed with a great deal of lead sulphate, it will suffer decomposition only very slowly through the agency of the supporting plate, but the lead peroxide on the positive plate, being mixed not only with lead sulphate, but with spongy metallic lead, will be itself speedily reduced to sulphate. Hence, on breaking the circuit, when local action alone can take place, the peroxide formed on the positive plate during the discharges will be destroyed much more easily than the original peroxide on the other plate. The difference of potential between the plates will be restored, and on connection the cell will be again found in an active condition.

Now it has been frequently observed that partially discharged accumulators do give an increased current after repose, that is, after the circuit has been broken and re-established. It remained for us to ascertain whether the chemical change above described coincided in any way with the physical phenomena. For this purpose we prepared plates according to the method of Faure, and examined carefully the changes of electromotive force and strength of current, which took place during their discharge under known resistances, and the chemical changes that took place under the same circumstances.

We found that the initial electromotive force of freshly prepared cells was 2·25, 2·25, 2·21, and 2·31 volts, averaging 2·25, but that after standing for thirty minutes or so, or when allowed to discharge for a few minutes, it was reduced to about 2·0 volts. We take this to represent the normal electromotive force of the arrangement of lead, lead peroxide, and dilute sulphuric acid, and believe that the higher figure obtained at the first moment is due to the hydrogen and oxygen occluded on the respective plates, and which either diffuse out or are speedily destroyed.

We found, however, that in the discharge the electromotive force diminished under certain conditions. Thus, in an experiment in which the external resistance was 1 ohm, and the internal 0·58 ohm, the E.M.F. sank in forty-five minutes from 2·25 to 1·92, but after being disconnected for thirty minutes, it was found to have risen to 1·96, and after eighteen hours' repose it had actually risen to 1·98 volts. These observations were made many times in succession during the course of the experiment which lasted six days.

With twenty times the external resistance, the diminution of electromotive force was much slower; but after discharging three days, the fall was more pronounced, and the rise on repose very apparent.

With 100 ohms resistance the electromotive force varied very little for three days.

It is more difficult to obtain satisfactory chemical evidence of a quantitative character. It is clear that as chemical examination means the destruction of the substances, the same plate cannot be analysed in two consecutive stages. Nor can two plates be easily compared with one another, although they have been formed under the same circumstances. Even the same positive plate, during or after discharge, presents to the eye very different appearance in different parts. To a certain extent we obviated this difficulty by cutting the plate in two, longitudinally,

analysing the one half at once, and allowing the other to repose for a given time before examining it for peroxide of lead.

As to the estimation of peroxide in the presence of metallic lead, we finally adopted as the best method that of reducing it by means of oxalic acid, although we were not certain that the whole amount is obtained in this way, even though the solution be kept hot for a considerable time.

By this method many chemical examinations were made of the positive plate. The results are as follows:—First of all, when the external resistance did not exceed 20 ohms the peroxide of lead was generally visible in patches, and its presence was demonstrated and approximately measured by various chemical tests. On repose, the quantity of this peroxide visibly diminished, and in the majority of instances the chemical analyses also showed a smaller amount. In all cases sulphate of lead makes its appearance early in the action, and gradually increases in quantity, becoming finally the only product of the discharge.

The deposit on the negative plate shows the presence of nothing but sulphate of lead in addition to the unchanged peroxide. At the conclusion of the action we have always found more or less of this substance unaltered. Thus, as one instance, after a discharge lasting five days, and approximately complete, we found that only .68 per cent. of the deposit was lead sulphate

We conclude therefore that the chemical action of the discharge is essentially what is expressed by the following theoretical formula:—

$$PbO_2 \mid H_2SO_4 \mid H_2SO_4 \mid Pb = PbO \mid H_2O \mid H_2SO_4 \mid PbSO_4,$$

which becomes

$$PbSO_4 \mid H_2O \mid H_2O \mid PbSO_4.$$

This reaction is, however, sometimes complicated by the formation of a small amount of peroxide of lead on the positive plate. We believe this to be due to the oxidation of sulphate, an action which was explained in our last paper.

Another conclusion has reference to the resuscitation of power observed on repose. This is not due to any purely physical action, but is a necessary consequence of the formation of PbO_2 on the positive plate. As sooner or later the result of the action becomes solely $PbSO_4$, this temporary formation of peroxide does not seriously affect the quantity of electrical force that may be regained from the accumulator, but it does affect the evenness of its flow. The flow is more regular if the discharge be made slowly, but in that case the loss on the negative plate from local action will probably be greater.

As to practical conclusions, we may note—1. Although, as stated in our paper of March 9th, the most economical arrangement for the initial charging of the cell is to "make the red lead to be hydrogenated much smaller in amount than that to be oxidated," yet, as foreshadowed in the same paper, this arrangement is not desirable for the discharge of the cell. Nor is it for its subsequent charging, since, as will have been seen, the substances to be acted upon are now very different. On the negative plate there will be the sulphate of lead produced by the discharge, plus sulphate of lead, produced by local action, together with more or less unaltered peroxide. On the positive plate there will be the sulphate of lead produced by the discharge, together with excess of lead, if any. Unless, therefore, the peroxide of lead unacted upon is allowed to be very considerable, the quantity of lead compound on the two sides ought to approach equality. 2. Care should be taken that sulphuric acid is in sufficient excess to allow of there still remaining some of it in solution after all the available lead has been converted into sulphate. If it is removed and only water is present, an oxide or hydrate will be produced with probably some serious consequences to the cell.

PATENTS FOR SIX MONTHS.—The number of applications for patents during the first six months of the present year amounted to 3,102, exhibiting a marked increase over those of the corresponding period of 1881, when only 2,865 applications were recorded. London furnished 775, the United States 397, France 261, and Germany 250. The electric light occupies a very prominent position amongst the inventions.

HARRISON, COX-WALKER & Co.'s TELEPHONE CALL.

THE object of this apparatus (devised and patented by Mr. Anders, formerly electrician to the American Bell Telephone Company) is to enable any one subscriber out of a number looped in on a single circuit, either to be called by the central exchange office, or by any other subscriber.

The whole apparatus is of a very simple nature, and consists of two keys and an indicator at each office or station; this indicator is shown in outward appearance by fig. 1.

One of the two keys sends positive currents, whilst the other sends negative currents; these two keys are of ordinary construction and do not possess any peculiarities.

The indicator at each station is in outward appearance similar to fig. 1, the hand is worked by a step-by-step propelment, worked by an electro-magnet with a polarised armature pulled in one direction by a spring, so that only the intermittent currents sent by one of the two keys will actuate it and work the hand round the dial. As all the indicators are similarly worked, and as they are all looped in on one circuit, it follows that they will all move in unison when intermittent currents are sent by the key referred to.

The general working of the apparatus is as follows:—the index hands of all the instruments being at zero, any station who desires to call, depresses key No. 1 several times (the reason of this will be afterwards explained), he then does the same with key No. 2, so as to send intermittent positive currents, say, out to line, and this he continues to do until he has worked the hand of his indicator round to the number of the subscriber whose attention he desires to call. This being done he next again depresses and raises key No. 1 several times, this has the effect of sounding a bell in the instrument of the subscriber referred to. After the communication is finished, he again sends intermittent currents from key No. 2, so as to work the index hand of his apparatus round to zero; when, however, this has taken place, he still continues to alternately depress and raise his key a few more times, though this operation will not cause those index hands which have arrived at zero to advance further, since they become arrested at the latter point by a stop; those hands, however, that may have accidentally lagged behind will, by the few additional currents, have been brought to zero.

Now the first operation which took place—namely, the depression of key No. 1—had for its object the release of all the index hands from the zero stops against which they had become arrested, so that when key No. 2 was depressed they would be free to move forward. The way in which this releasing is effected, and the means by which it happens that only the bell at the office of the subscriber it is desired to call is rung, will be understood from figs. 2 and 3, the latter being an enlarged general plan of portions of the mechanism.

Referring to fig. 2, *w* is a propelment wheel actuated by an anchor attached to a soft iron tongue. This tongue is polarised from its lower end by one end of a permanent steel magnet, M, and plays between the two poles of two electro-magnets, whose other poles are connected by a soft iron strap. The anchor is normally pulled over to the right by a spiral spring (not seen in the figure).

A second soft iron tongue, *t* (*see* fig. 3), is polarised by the second pole of the permanent magnet, M, and this tongue also plays between the poles of two electro-magnets. The four electro-magnets are connected together in one circuit, the connections being so made that when the magnets are excited, one tongue tends to move to the right, whilst the other tends to move to the left. It is evident, therefore, that as one tongue is normally drawn to the left by a spring, and tongue, *t*, is normally pressed to the right by another spring, that currents in one direction only affect the former, whilst currents in the opposite direction only affect *t*.

Referring now to fig 3, *w* shows the propelment wheel, a portion of which is broken away to show the disc, *f*. This disc is fixed to the same axle as *w*, and turns with it. To the tongue, *t*, which is axled at *h*, is fixed the curved wire, *k*, to

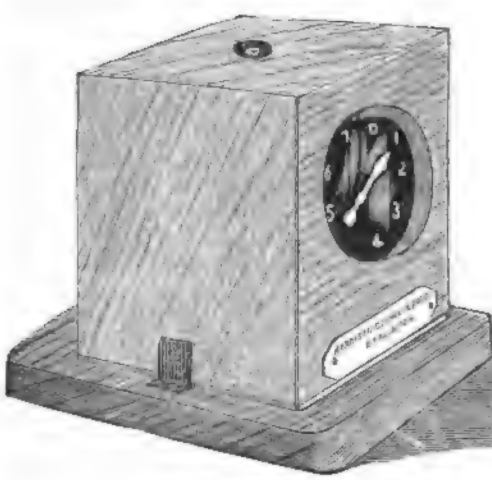
the extreme end of which is attached the bell hammer (*see* fig. 2). Attached to *k* is a small projecting piece, *d*. This projecting piece being in a line with the disc, *f*, presses against the circumference of the latter when *k* is moved to the right by the attraction of the tongue, *t*, thus the hammer at the end of *k* is prevented from striking the bell. When, however, the disc has, by the movement of the wheel, *w*, become turned round so that the notch, *g*, comes opposite (or nearly opposite) *d*, then *k* can have its full movement and its hammer can strike the bell.

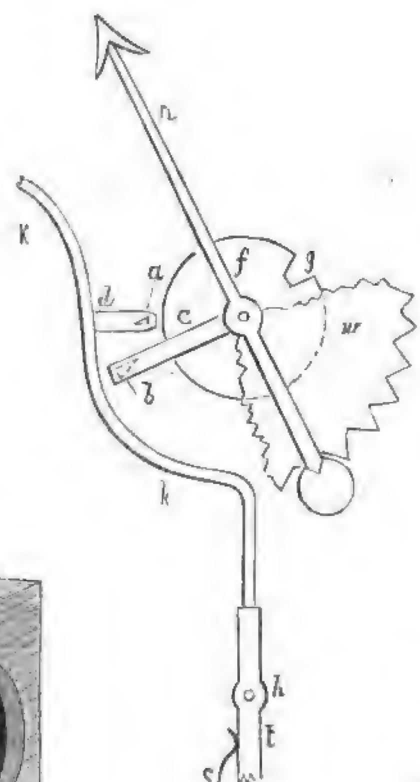
On the axle on which *w* and *f* are fixed is secured an arm, *c*. This arm has near its end and on its inner face a small wedge-shaped projection, *b*. The piece, *d*, has a similar projection, *a*, on its outer face. Now supposing *k*

These latter currents, as explained at the beginning of the article, are sent at the commencement of the calling operations.

Now by so setting the position of the notch, *g* (on the disc, *f*), in the various instruments that the notch in, say No. 7 instrument, comes opposite the piece, *d*, when the indicating hand of No. 7 points to that number, then it is evident that the bell of No. 7 only can be sounded when the index hands of all the instruments point to 7; and similarly if all the hands point to 5, then the bell of No. 5 only can be sounded.

As the wheel, *w*, has forty teeth cut on it—that is to say, as five movements of the anchor will be required to move the index hands from one number to the next, and as the





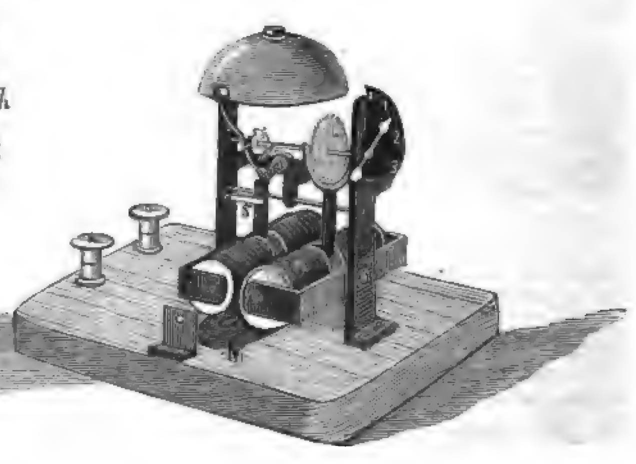


FIG. 1. FIG. 3. FIG. 2.

to be in its normal position, then, if the arm, *c*, becomes moved round, the projection, *b*, will come in contact with the projection, *a*, and the movement of *c*, and consequently also of the hand, *n*, will become arrested; in this position *n* points to zero on the dial.

Now the position of the arm, *c*, is so arranged with reference to the wheel, *w*, that when *b* has been worked round so as to be just in contact with *d*, then the propelment anchor is just on the point of moving *w* under the influence of the retractile spring. Under these conditions it follows that if *k* be moved slightly to the right by the action of the electromagnet acting on *t*, so as to free *a* from *b*, then the wheel, *w*, will move slightly forward by the propelment anchor being pulled quite home into the teeth of *w* by the spring. When, therefore, *k* drops back to its normal position, the projection, *a*, will come underneath the projection, *b*, and the movement of *c* will no longer be prevented. Thus the wheel, *w*, and the pointer, *n*, are free to move. We thus see that when a series of intermittent currents in one direction are sent by key No. 2, the wheel, *w*, and the indicator hand, *n*, can be worked round to zero, but no further, and that in order that the rotation may be continued it is necessary to move *k*, which is done by a current, or currents, sent by key No. 2.

notch, *g*, is made sufficiently broad—an accidental skip of one or two movements of the anchor in the course of the revolution of the wheel, *w*, will not prevent the bell ringing at the proper station. Such accidental skipping as has been pointed out will be corrected at the final stage of the calling operation by bringing all the hands up to the zero stops.

HASKINS' ARC ELECTRIC LAMP.

THIS is the invention to which we alluded in a short note last week under the name of the "Diamond" arc lamp. We now purpose entering more fully into its construction and design, for although any person can devise an arc lamp differing in some points from preceding specifications, and notwithstanding that the number of such lamps is legion, there are decidedly merits in the invention under discussion which deserve more than a passing notice. Mr. Haskins is well known in America, and here also, as a leading electrician, and on this account alone one would naturally expect something out of the ordinary from his inventive faculties. The lamp in question, as we have before stated, is to be seen in

action at 874, Euston Road; the current necessary for producing the light being supplied by a Weston dynamo-electric machine. Before entering into a description of the Diamond arc lamp we will briefly call the attention of our readers to a somewhat similar idea of Mr. Haskins, which we extract with an illustration (*see* fig. 1) from the *Official Gazette* of the United States Patent Office. The number of this patent is 261,091, and was filed in the

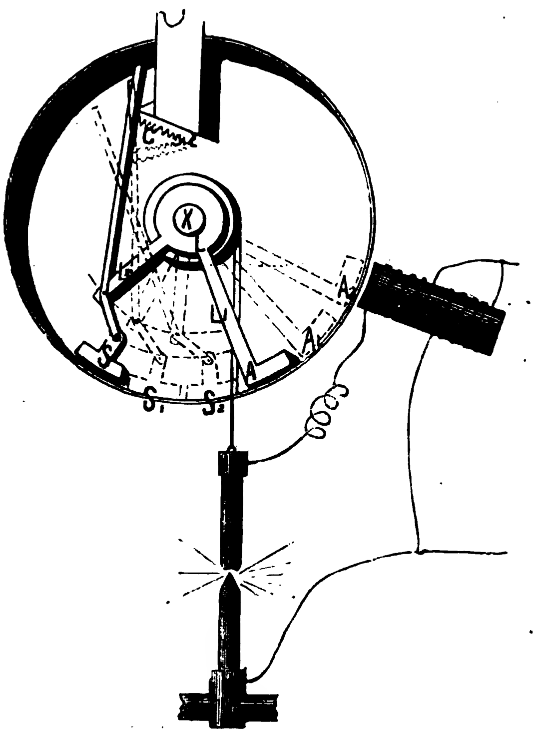

FIG. 1.

United States of America Patent Office January 25th, 1882. The claim of Mr. Haskins which follows will sufficiently explain the sketch :—

"The combination, substantially as hereinbefore set forth, of the movable electrode of an arc lamp, an electro-magnet vitalised by the light-producing current, and an intermediate

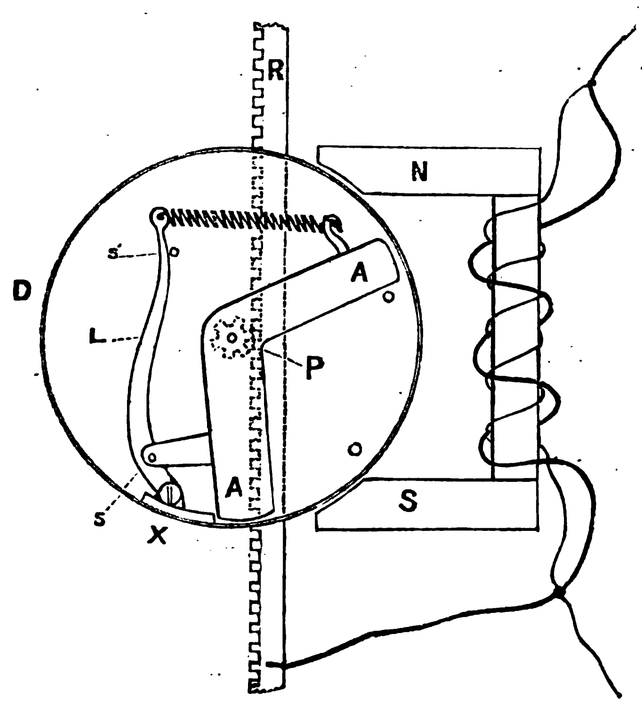

FIG. 2.

regulating mechanism consisting of a drum mechanically connected with said electrode, and an armature and a clamping-lever connected together and pendulously suspended from the axis of said drum, said clamping-lever being adapted to act against the inner periphery of said drum."

It is evidently intended that the fine wire of the electro-magnet shall, when the current passes through, partially demagnetise the core; or rather weaken the magnetism produced in the core by the main current flowing through the thick coil.

Most of the arc lamps at present in operation have the lower carbon fixed, and the upper one is allowed to approach the lower when necessary by its weight alone. The object of the electro-magnetic devices of various forms employed in such lamps is usually for the purpose of parting the carbons, thus forming the arc, regulating the length of the arc, and also for releasing the grip or clutch holding up the top carbon, so that it may descend towards the lower when the length of arc increases beyond its normal state. In the same manner the Haskins lamp depends upon gravity for the descent of the upper carbon, and an electro-magnetic apparatus, or feeding mechanism, applied to the upper carbon regulates its action. In the following sketch of the working parts of this invention, fig. 2, it will be seen that the upper carbon holder is shown—as in many other lamps—as a light toothed bar or rack, R. This gears into a pinion, P, fastened to the centre of a flanged disc, D, which is accordingly rotated by the lifting up or falling of the rack. To control the downward movement of the carbon holder it is only necessary to apply a brake to the inside rim or flange of this disc, and as this latter may be of any required size, the power requisite to check its motion and resist the weight of the carbon holder may be very small, and the magnetic attraction necessary for this purpose may, therefore, be comparatively slight. The brake is shown in the figure at X, and forms the foot of a bent lever, L, pivoted at *s* on one arm of the armature, A, A. This armature is pivoted at the centre of the disc, D, about which it swings freely in response to the varying magnetic attraction of the poles, N, S, of the electro-magnet. It is claimed that on account of the manner in which the armature is hung between the poles of the electro-magnet a very slight attraction serves to deflect it, and as the leverage with which the attractive force acts upon the armature decreases as it approaches the poles, the magnetic pull is uniform throughout the entire movement, instead of being subject to a violent variation, as is the case when an armature approaches the poles in the line of the magnetic attraction.

The core of the electro-magnet is wound with two coils, one of thick and the other of thin wire. In the lamps as actually used, the thin wire is wound first upon the core, and the thick coil outside this. The main circuit includes the carbons and the thick wire, the fine coil being in a derived circuit or shunt to the arc. When the lamp is ready for action and the carbons touching, all the current except the little passing through the fine wire coil, goes through the main path, and the electro-magnet is, therefore, strongly magnetised. The armature at both ends is attracted and carries with it the brake, X, which clamps against the inside rim of the disc, D. Any further motion of the armature must then necessarily turn the disc, which raises the upper carbon, thus establishing the arc. Suppose that only the thick wire coil is wound upon the electro-magnet, then as the current weakens through the lengthening of the arc, as the carbons consume, the ends of the armature not being so strongly attracted swing away from the poles of the electro-magnet, and in so doing the carbon is lowered to a slight extent. When it reaches the position in which the upper end of the lever, L, bears against the pin, S^1, the brake, X, is released, and the carbon is free to slide downwards. Since the magnetic attraction is applied in a way to render the device equally sensitive to currents of different strengths, and since, on account of the leverage obtained by the disc, a comparatively feeble current can overcome the weight of the carbon, a small arc can be as readily formed as a large one. The lamp automatically adjusts itself to the current sent through it, and the brake needs no adjustment, as the armature simply moves through a less or greater distance, forming a short or long arc, as the current increases or decreases in strengh. The use of the fine wire coil is explained as follows :—With only the thick wire on the electro-magnet, the light remains constant only as long as the current itself is so. Considerable fluctuations in this current, such as occur when a number of lamps are in circuit, will therefore cause an unsteadiness of the light, unless some arrangement is provided for equalising the variations. This is the duty of

the fine wire coil, which provides a path for the current around the arc, and as the direction of the current through it is in a contrary direction to that passing by the thick wire, it constantly tends to weaken this. When the current greatly increases, the shunt coil takes its share of the increase, thus tending to diminish the excess of current in the thick coil. This appears an odd way of explaining the use of the fine wire circuit, which is simply to partially neutralise the

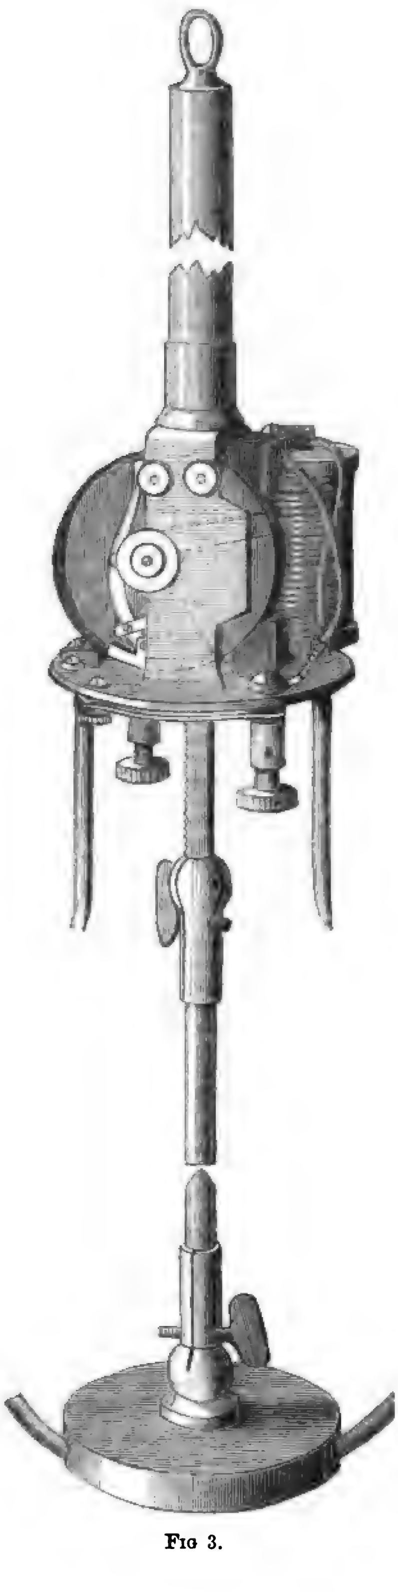

FIG 3.

magnetism developed in the core of the electro-magnet by the current which passes through the thick coil. Of course, if an abnormal resistance should occur in the main circuit of the lamp, the carbons would quickly drop together, and start afresh.

The general view of the mechanism of this lamp is shown in fig. 3.

We are indebted for portions of our description to the pamphlet of the Union Electric Manufacturing Company of New York, and for the last sketch to the courtesy of Mr. Newson, of Isleworth, the agent for the sale of the patent rights of this lamp in Great Britain and Europe, who kindly sent to our office a lamp from which the drawing was made. It would be hard to find a lamp on the arc system, with one carbon above another, to equal this. There is apparently nothing whatever of a delicate nature in its whole construction, and therefore the liability to derangement is reduced to a minimum. The disc, with the friction brake, is a capital arrangement, and it will be seen that *both* poles of the electro-magnet are usefully employed. The use of a shunt circuit for demagnetising or reducing the magnetism produced by the main coil, although not new, is well adapted to its purpose in the Haskins lamp. The nearest approach to this invention which we can call to mind at the moment is the arc lamp of Mr. Andrew Common, who employed a disc and brake, and also a rack and pinion, and a shunt circuit, in opposition to his main coil. The two lamps, however, are in some other points dissimilar, especially in regard to the electro-magnetic apparatus, as in the last-mentioned lamp a solenoid was made use of. The proprietors of the Haskins lamp may rest assured that as far as merit is concerned it should take a leading position, not merely electrically, but commercially; and we can safely say that as far as compactness, simplicity, excellence of design, both electrical and mechanical, and lastly—for such a type of lamp—its extreme lightness, it can certainly hold its own. Having twice seen the lamp, we feel convinced of its superiority in several important points over most of those at present in actual operation.

Since writing our description of Mr. Haskins' lamp, we have received a copy of the following report on its merits. Mr. Farquhar is well known as an expert in electric lighting matters, and his opinion is therefore worthy of consideration :—

DEAR SIR,—In regard to the Diamond Arc Lamp, of which I have made a thorough test and investigation, I may state in a few words its superiority over other arc lamps.

1. The great simplicity of the mechanism used to keep the carbon points at an uniform distance; this same mechanism acting at the same time as the arc starter.

2. The comparatively light weight of the lamp which, complete, does not exceed 10 lbs. I do not know of any other lamp of equal lighting capacity as the one in question, which weighs so little.

3. As regards economy of manufacture, I should state confidently that the Diamond lamp, if manufactured on a large scale, would create quite a revolution in arc lighting, as the small cost of the lamp would overcome one of the great obstacles at present to economic electric lighting.

4. One great and important feature in the Diamond lamp is the relation of the parts and the law of their movements, the effect of which, without entering into details, is such that the lamp automatically adjusts itself to the current sent through it, that is to say, that the arc automatically lengthens if the intensity increases; the lamp therefore acts as a regulator, and affords always a proportional external resistance to the electromotive force of the machine supplying the current; this in a great many instances of practical electric lighting would save serious injury to the dynamo machines.

In conclusion, I may say that after six years of busy employment in practical electric lighting, I have never seen a lamp that recommends itself more to the purpose for which it is intended than the Diamond Arc Lamp.

Yours truly,

—— HEARINGTON, Esq., CHAS. W. FARQUHAR.

374, Euston Road.

17th July, 1882,

FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The eleventh session will be held at La Rochelle from the 24th to the 31st of August, 1882. The programme of the session comprises a general inaugural meeting, section sittings, scientific or industrial visits, public conferences, and excursions. Several questions relating to electricity will be treated; amongst others we may mention a paper by M. Marcel Brillouin on the method of comparing co-efficients of induction; the causes of errors and the means of avoiding them; a communication from M. Debrun, Professor at the Lycée of Paris, on a capillary registering electrometer, and the general distribution of electricity. M. Tissandier will expound his researches on small batteries, and M. Hospitalier will hold a conference on the electric light. We shall endeavour to keep our readers well informed concerning the electrical subjects presented to the association.

CORRESPONDENCE.

TO CORRESPONDENTS.

No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer, not necessarily for publication, but as a guarantee of good faith.

Correspondence should arrive not later than Tuesday morning if it is desired to appear in the following number.

THE TELEPHONE.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—In your issue of the 15th of July, Mr. Henry C. Buck thinks fit to criticise the criticism of M. Le Comte du Moncel, and claims that Professor E. Dolbear was the first to apply the vibrations of a condenser to the construction of a telephonic receiver; but he must have forgotten that Mr. Varley, some years before the invention of the Dolbear telephone, constructed an apparatus in which a Reiss transmitter and a battery were inserted in the circuit with the primary wire of an induction coil, to the secondary of which was attached a condenser, which was found to reproduce sound nearly as well as the Reiss receiver. Thus it would appear that the only improvement made by Professor Dolbear was the substitution of flexible plates for the packed condensers, and the use of a transmitter producing undulatory currents instead of intermittent ones.

Yours faithfully,

F. D. WOLFFERS, FILS.

56, Portland Place, Clapham, S.W.
July 19th, 1822.

CARBONISING PROCESSES.

To the Editors of THE ELECTRICAL REVIEW.

DEAR SIRS,—Can you, through the columns of your valuable journal or by letter, give me any information in regard to the Bertholetti process of carbonising? Can you give me the name of any work referring to the subject of carbonising? Very truly yours,

FRED. L. HARRIS.

20, Nelson Square, S.E., *July 25th*, 1882.

[We will endeavour to find the information our correspondent seeks, and in the meantime perhaps some of our readers may be able to supply his wants.—EDS. ELEC. REV.]

THE CRYSTAL PALACE ELECTRICAL EXHIBITION.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Having read "Disque's" letter and your paragraph in your last issue, I should be glad if you would find room for my experiences.

Having had cause to make complaints (as who had not), I adopted the usual course of writing to the management. This being without avail I requested that a deputation from a certain section of exhibitors should be received by the directors. After some delay a reply was forwarded, stating that the chairman and manager would be pleased to hear us. The usual soft soaping took place, and things became worse than before.

I then wrote to the Lord Mayor, whose name heads the list of the Honorary Council of advice. In due course I received a reply from his secretary to the effect that the Lord Mayor knew nothing of the matter, and had forwarded my letter to the Crystal Palace authorities. Of course, I heard nothing further, and concluded the game was not worth the candle.

All exhibitors should now combine and insist upon the directors making the awards known at once, failing which they should decline to enter for the forthcoming exhibition. The Honorary Council of Advice is much too honorary to be troubled with the matter. Yours truly,

F. W. POPE-COX.

Salisbury Hotel, London, *July 26th*, 1882.

We have received from Prof. Silvanus Thompson an important letter on the subject of the telephone, but unfortunately too late for insertion in the present number.—EDS. ELEC. REV.

NOTES.

KENNEDY'S ELECTRIC-LAMP PATENTS.—With reference to a statement which appeared at page 386 in the "Notes" of our issue dated 27th May last, we are now able to state on authority, that all oppositions to the patents applied for by Mr. Kennedy, No. 5524 of 1881, No. 1199 of 1882, the latter being the "Solenoid Arc Lamp Patent," have been withdrawn. With reference to the latter, it is important to state that the opposition to it was withdrawn after a declaration had been filed by Sir William Thomson, pointing out the important differences in Kennedy's Arc Lamp over any lamp which had preceded it. The only reason we had for stating what we did was the fact that nothing was mentioned concerning this matter in the Company's prospectus. We are glad to note that these oppositions have not led to any difficulties or complications whatever, that both patents are now completed, and the necessary arrangements carried out under them with the Railway and Electric Appliances Company (Limited).

SCIENTIFIC REPORTS ON ELECTRIC LIGHTING.—We drew attention last week to the extract of Mr. J. E. H. Gordon's report on the "Rogers" incandescent electric lamp, which was published in the daily press during the last day or two remaining, for applications for shares in the J. B. Rogers Electric Light Company. We notice the following letter in the money article of the *Times* of Saturday last:—

"28, Collingham Place, Cromwell Road, S.W., July 21.

"Sir,—I observe in the *Times* of yesterday an advertisement of the J. B. Rogers Electric Light Company, in which it is stated that the full report can be seen at the office.

"On sending to the office I find that this is not the case, as only that portion of my report which alludes to the lamps is shown.

"I shall be obliged if you will permit me to state through the *Times* that my report embraced both the incandescent lamps constructed by Mr. Rogers and the 'system of subdivision' patented by him, and that I stated that the so-called system is worthless. About the rest of the nine patents advertised I have expressed no opinion, as they have not been submitted to me.

"Your obedient servant,

"J. E. H. GORDON."

We cordially endorse Mr. Gordon's opinion on the worthlessness of the system of subdivision, and we can only regret that publicity was not given to this matter before the closing of the share list. That, however, is not Mr. Gordon's fault, for the J. B. Rogers Company apparently took care that his disclaimer should not meet the public gaze until it was useless, for the reason above stated. The same letter was also published, we believe, in the *Standard*, and has called forth the following reply, which appeared in that newspaper on Wednesday:—

SIR,—The attention of the directors of this company has been called to a letter in the Money Article of yesterday's issue of your paper, signed J. E. H. Gordon, in which he states erroneously that a certain report made by him on some of Mr. Rogers' patents was omitted from the report produced at the company's offices to his representative. We are directed to inform you that our clients have never had but one report of Mr. Gordon's, *i.e.*, that on Mr. Rogers' Incandescent Lamp, and that has been produced in its entirety to every applicant who has applied to inspect the documents set out or referred to in the prospectus of this company. The directors have made inquiries of Mr. Rogers and the promoters whether or not any other report of Mr. Gordon's has been made on Mr. Rogers' patents, and they find that Mr. Gordon's draft report did contain an opinion on the "System of Distribution" that Mr. Rogers was mistaken in his views on the subject, but that portion of the report was struck out by Mr. Gordon, and omitted in the fair copy report signed by him and received by the directors.

We refrain from further observations pending the result of counsel's opinion as to the course the directors should adopt in consequence of the publication of Mr. Gordon's letter.

We are, Sir, your obedient servants,

WEST, KING, ADAMS, and CO.

Cannon Street, London, E.C., *July 25th*.

THE ELECTRIC LIGHT IN EGYPT.—Lieutenant Dickin, of the *Alexandra*, has succeeded in establishing the electric light at Fort Comeldikh.

THE ELECTRIC "SUN" LAMP AND POWER COMPANY.—It is announced that the letters of allotment for the shares of the Electric "Sun" Lamp and Power Company (Limited) were posted on Wednesday evening.

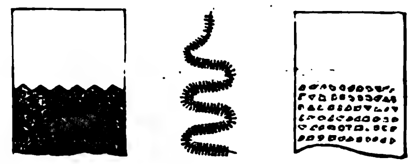
THE ISLAY CABLE.—We understand that the ss. *Morna*, now off Silvertown, will start this morning to repair the above cable.

THE ELECTRIC LIGHT IN THEATRES.—We extract from Thursday's *Standard* the following note from the Paris correspondent of that paper :—"The disastrous fires in theatres, which have lately entailed the loss of so many lives, have induced the Prefect of Police to study the question of lighting places of public amusement, with the view of, if possible, lessening the danger entailed by the use of gas. Till now no very satisfactory result had been achieved. Many experiments with various electric lamps had been made, but all had required the presence in the building of an engine to supply the lamps with electricity. Last night a step was, however, made in the right direction. The Variétés Theatre was lighted up by the English Faure Electric Accumulator Company ; the whole house, the stage, footlights, corridors, and green rooms were all lighted with the Swan incandescent lamp. The intensity of the light was very successfully regulated, and the footlights turned on and off with great rapidity. The heat was also very much less than that occasioned by the use of gas. The spectators at these private experiments, among whom were M. Camescasse, almost every theatrical director in Paris, theatrical critics, and many Deputies and Senators, pronounced most favourably on them."

ANOTHER "BRUSH" COMPANY.—We have received the prospectus of the "Brush" Electric Light Company of Ireland (Limited), which has been formed to supply in Ireland electricity for public and private lighting, as a motive power and for other purposes. It has secured concessions from the Anglo-American Brush Corporation for the use of the rights and patents of the latter. The capital is £250,000, of which £130,000 are to be issued now, in 26,000 shares of £5 each. Two thousand shares will be issued as fully paid to the vendors, who will also receive £22,500 in cash. It appears from the prospectus that the company is to take over the business and plant of the Dublin Electric Light Company (Limited) and 6,370 shares are reserved for that purpose. The company is expected to profit largely by "granting sub-licences to local companies." This mode of operating has, no doubt, worked very well, so far, for the original "Brush" Corporation, but is not, as it appears to us, capable of unlimited development, and unless some more solid and lasting earning capacity than this is possessed by the companies which have made it their chief reliance, their profits will cease shortly. It is, perhaps, too much as yet to expect them to show any very large volume of regular business, but in nearly all the prospectuses of this class of companies which have come before us the principal inducement offered to investors is the possibility of selling a concession to some third party, a legitimate operation enough, but one which *ex vi termini* cannot constitute a permanent source of revenue.—*The Times.*

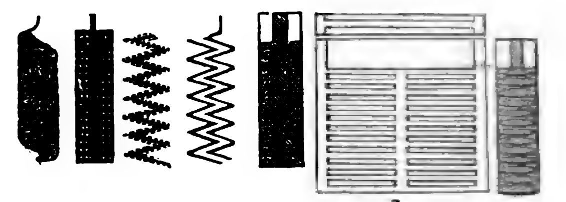
THE HOLBORN GUARDIANS AND THE ELECTRIC LIGHT.—In consequence of the great increase in the gas bill for the infirmary during the last year, notwithstanding that there was a reduction in the price, the board, a short time since, invited tenders for lighting the establishment with the electric light, and the tenders received were as follows : Messrs. Siemens Brothers, £5,000 ; the Brush Electric Lighting Company, £4,345, and Messrs. Pilsen, Joel and Company, £3,143. The Infirmary Committee reported that the matter was referred to Messrs. Snell and Sons, architects to the board, to report thereon. The committee stated that they had awarded the best thanks of the committee to Messrs Snell and Sons for their careful and elaborate report, and the committee report to the board that in their opinion it is not advisable to use the electric light at the establishment. Mr. Ross moved the adoption of the report. It was shown that the expense of the electric light was such that they could not think of adopting it at present. Mr. Whiting thought that the subject had not received proper attention, and that another committee might bring up a more favourable report. The present gas-fittings could be adapted to the electric light, and they would get rid of the vitiated atmosphere. The report was then approved. This matter formed the subject of Mr. Snell's correspondence with several of our contemporaries.

SECONDARY BATTERY.—Patent No. 260,654. Filed in the United States of America Patent Office, June 15th 1882, by Charles F. Brush :—



Claim.—The method of forming the plates of a secondary battery consisting in forming receptacles for oxide of lead in its surface, then applying oxide of lead to the plate and within such receptacles, and afterward subjecting the oxide of lead to pressure.

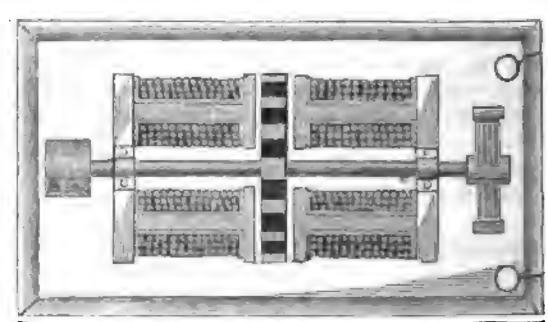
SECONDARY BATTERY.—Patent No. 260,653. Filed in the United States of America Patent Office, June 15th, 1882, by Charles F. Brush :—



Claim.—In a secondary battery, an element consisting of a structure of etagère-like form, containing in the spaces between its shelves lead in a finely-divided state, substantially as set forth.

DYNAMO-ELECTRIC MACHINE.—Patent No. 260,652. Filed in the United States of America Patent Office, June 1st, 1880, by Chas. F. Brush.

Brief.—Surrounds the cores of the field-magnets with a continuous band of sheet copper or other suitable conductor. Over these bands are coiled the magnetising helices in the customary manner, the purpose being to avoid extra currents.



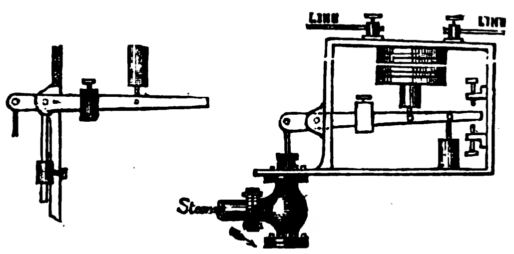
Claim.—1. In a dynamo-electric machine the combination, with the moving coils or bobbins of conductors, of field-of-force magnets having their cores encircled by one or more closed conductors, substantially as set forth.

2. In a dynamo-electric machine the combination of the moving coils or bobbins of conductor within which the electric current is induced, and one or more field-of-force electro-magnets that are surrounded by one or more closed diamagnetic conductors, substantially as and for the purposes set forth.

3. In a dynamo-electric machine, the combination, with the moving coils or bobbins of conductor within which the electric current is induced, of one or more field-of-force electro-magnets that are surrounded by one or more closed diamagnetic conductors, and an exciting helix or helices, also surrounding said field-magnets, substantially as set forth, whereby the insulation of the apparatus is preserved during fluctuations in the current exciting said field-magnets.

INCANDESCENT ELECTRIC LAMPS WITH CARBON FILAMENTS.—We have heard on very good authority that the Edison Electric Light Company has resolved to apply for an injunction against the Swan Electric Light Company, on the ground that the Swan lamp is an infringement of the Edison patents. The case is to be decided before Mr. Justice Chitty, we believe, and indeed, unless other arrangements have been arrived at in the meantime, the case may have been heard before this meets the eyes of our readers. Should the intention of the first-named company be carried out, it will be interesting to see whether the result will be of a like character to the recent telephone trial.

CURRENT GOVERNOR FOR DYNAMO-ELECTRIC MACHINES.—Patent No. 260,650. Filed in the United States of America Patent Office, June 29th, 1880, by Charles F. Brush.



Brief.—An axial magnet in the main circuit controls a lever connected with the valve, which admits steam to the engine which drives the generator.

Claim.—1. In a system for generating and applying an electric current, the combination of the following-named instrumentalities, to wit: A dynamo-electric machine, a motor for driving said dynamo-electric machine, an external or working circuit upon which is placed one or more electric lamps, electro-motors, or any device to be operated upon or actuated by the electric current, and a governor consisting of a hollow or axial magnet that is energised by current from said dynamo-electric machine, and that is associated with suitable valve or cut-off mechanism, said governor constructed and adjusted to control the speed at which the dynamo-electric machine is driven, according to the varying condition of the current in said external or working circuit, substantially as shown.

5. In combination with an electric governor for regulating the speed at which a dynamo-electric machine is driven, the pendant weight substantially as and for the purpose shown.

ELECTRIC LIGHT AT BEACONSFIELD HOTEL, ADDISON ROAD STATION.—We understand that Mr. W. Cooke, the proprietor, intrusted the installation of the electric light in the above hotel to Messrs. Charles Powis & Co., of Millwall Pier and 60, Gracechurch Street, engineers and electric light contractors. The entrance lobby, bar, and billiard room (containing two full sized tables) are brilliantly lighted with eighty Swan incandescent lamps, and the exterior with a Siemens arc lamp. A Siemens alternating current dynamo-electric machine, driven by an eight horse-power (nominal) gas engine, is fixed in the basement. This installation, which is said to be a permanent one, was officially started on the evening of Saturday, the 15th inst. (the opening day), in a most satisfactory manner, and was witnessed by a large number of Mr. Cooke's friends and customers, who were present during the whole of the evening and expressed themselves highly satisfied at the steadiness and brilliancy of the light.

CHESTERFIELD AND THE ELECTRIC LIGHT.—At a meeting of the Chesterfield Town Council last week a letter was read from the Hammond Electric Light and Power Supply Company asking, in view of the passing of the Electric Light Bill now before Parliament, for the consent of the corporation to run wires under the streets of the borough for the purpose of private lighting. The Mayor pointed out that the request was one of very great importance, for compliance with it would give the company a monopoly of public and private lighting by electricity in the borough. After some discussion it was agreed to refer the application to the Watch Committee.

THE INSURANCE AND THE ELECTRIC LIGHT.—It is reported from America that the fire insurance companies of Philadelphia have decided to cancel policies wherever they find electric conducting wires attached to the roofs of buildings on which they have outstanding risks.

THE ELECTRIC LIGHT AT SYDNEY (N.S.W.)—At a recent meeting of the City Council of Sydney a proposal was received from a London gentleman interested in the formation of syndicates, offering to light the streets and public buildings of Sydney by electricity at a cost of 25 per cent. less than the contract price of the gas now supplied.

THE AUSTRIAN REGULATIONS FOR THEATRES.—From the new Austrian Regulations for Theatres we extract the following:—Electric light: When a theatre is lighted by electricity the installation must be arranged so that the illumination of the auditorium is wholly independent of that of the stage. In all the parts of the theatre the installation must provide two separate systems and independent circuits, each with its lighting machines and apparatus. The wires must be sufficiently stout to prevent their being overheated; they must be carried along a groove in the wall, and secured against being injured, as well as against the possibility of the audience coming in contact with them. The electric light must be provided with glass globes, and so fixed that it is impossible for particles of the carbon points to fall out. Motors driving the machines must in cases where fire is employed in them be fixed up outside the theatre building. Fire telegraph: The theatre should be connected with the local fire brigade by telegraphic signalling apparatus which should be accessible not only in the parts of the house frequented by the *personnel* of the theatre, but also in the offices and the porter's lodge. The apparatus should be fixed near the mechanism for moving the fire-proof curtain, and attended to by the watchman looking after the latter. A similar apparatus should be placed in the offices and porter's room. The telegraph must be tested every day about noon, so that in case it should get out of order there may be plenty of time to repair it.

THE BRUSH ELECTRIC LIGHT AT WORCESTER.—The Fine Art Court at the Worcester Industrial Exhibition is illuminated by Brush lamps supplied by the Birmingham and Warwickshire (Brush) Electric Light Company, and the installation is, we understand, giving great satisfaction.

GAS MANAGERS AND THE ELECTRIC LIGHT. — The twenty-first annual meeting of the North British Association of Gas Managers was held in Edinburgh on the 21st inst., The president, in the course of his address said, "it was abundantly evident that cheaper gas must be made and supplied, and to accomplish this their energies must be at once directed. Economy must be the order of the day, and he was persuaded they should not be found lacking in the desire to inquire into and take advantage of such new or improved methods as might be devised and submitted to the profession for use. He did not say this because he feared the electric light, which, so far as he was able to judge, would never become commercially a rival of gas. He would rather hail "the light of the future" as a mission which had taught them what they were capable of accomplishing with gas, as was everywhere apparent in improved lighting. He was satisfied, too, that wherever electricity and gas were brought into competition, it had been well substantiated that gas was able to hold its own, as regarded cost, convenience, or reliability, and even, he would say effectiveness of illumination. At a subsequent meeting Mr. Donaldson described a ventilating globe light. He claimed that where these globes are used, the gas burned in them ventilates the room it illuminates, and in a sanitary point of view is superior to the electric light.

IMPROVEMENTS IN ACCUMULATORS.—In these times of new electrical companies we cannot too strongly recommend to capitalists the particularly ingenious method discovered by M. C. Blanchart, honorary engineer of the mines at Brussels, of obtaining electric accumulators of a capacity far superior to any that have been made at present—on paper, that is. We know that, according to the experiments of Sir W. Thomson, and those of MM. Tresca, Joubert, and Pothier at the Conservatoire des Arts et Métiers, at Paris, the Faure accumulators can store up work equivalent to one horse-power during one hour, with a weight of about 75 to 80 kilogrammes, or 4,000 kilogrammetres per kilogramme of accumulators under the most favourable conditions. M. Blanchart arrives at the figure of 11,371 kilogrammetres with his improved accumulators. Only—there is an only—M. Blanchart in his calculations only takes into account the weight of the lead and of the minium—the vessel and the acid are not reckoned—and besides, he says that the discharge is effected with a *constant* electromotive force of 2·15 volts, which is incorrect, since the intensity of the current through an unknown resistance at the commencement of the discharge is 13·33 ampères, and at the end it is only 8 ampères. This change

in the intensity is not produced without a decrease of electromotive force, but it is convenient not to take this into account in the calculations because it increases the total result. But there is still more to be said. M. Blanchart, by reckoning the weight of the oxidised plates only, and ignoring the fall of potential during the discharge, arrives at the fantastic figure of 23,600 kilogrammetres per kilogramme of active material. It seems to us, however, that the reduced lead which becomes oxidised during the discharge, may also be considered active material. Adopting M. Blanchart's method of calculation, rather less than 12 kilogrammes of active material were sufficient to produce one horse-power-hour of electrical energy. We sincerely hope this is the case, but it is impossible to accept it merely on the calculations of the inventor, who, aiming at simplification, ignores to too great an extent important factors. In conclusion, we may add for the benefit of those who may intend to verify our remarks, that M. Blanchart's calculations are given at length in the *Annales de l'Electricité* for July 15th, 1882, page 204.

THE ELECTRIC LIGHT.—Referring to the discussion which took place in the House of Commons on Saturday on the Electric Lighting Bill, the *Daily Chronicle* remarks that the gas companies may claim our sympathy if they are damaged by the new illuminant, but if their pretensions are eclipsed they must be satisfied with sympathy. If the new invention surpasses gas the public interest must override all sentimental ideas about vested interests. The gas companies have no vested interests; they have for many years enjoyed a monopoly in the lighting of public places, but they enjoyed that monopoly for the simple reason that their light was the best which could be procured. The advances made of late years by the electric light have produced a most beneficial effect upon the lighting of the London streets. But the recent exertions of the gas companies cannot prevent the progress of the new illuminant, and we are glad to find that the Government are determined that, so far as they can, they will secure for it a fair trial. Parliament has no right to consider the interests of the gas companies apart from the public convenience, and therefore local authorities will have an opportunity of adopting the new illuminant if they think fit. It would be absurd to suppose that this Bill will dispose of the opposition of vested interests. The electric light will have to fight its own way, and before it gains the goodwill of local authorities it will not only have to prove its superiority, but to overcome the private prejudices which the long-vested interests of gas have planted in every populous part of the country. As to the second objection to the Bill, we do not believe that the local authorities will be found to be at all too ready to rush into expense for the purpose of introducing the electric light. On the contrary, we expect rather to find a disinclination to admit the new illuminant.

CENTRAL AND SOUTH AMERICAN TELEGRAPH COMPANY.—The India-rubber, Gutta-percha and Telegraph Works Company notify the receipt of telegrams from Mr. R. K. Gray, engineer-in-chief, announcing the successful completion of two more sections by the ss. *Silvertown*, namely, from Salina Cruz, near Tehuantepec, Mexico, to Libertad, in San Salvador, and from Libertad to San Juan del Sur, in Nicaragua.

It would appear, therefore, that an alteration in the landing places has taken place. Instead of landing at San José de Guatemala, as was first intended, the Salina Cruz section now lands at Libertad, and thereby brings the republic of San Salvador in the company's system of cables.

The cable was further supposed to have gone from San José to Salinas Bay, in Costa Rica; but this section is now replaced by the Libertad—San Juan del Sur section, and through this the republic of Nicaragua enters the company's system.

Libertad is the principal harbour of San Salvador, and is connected by a good road with the capital, some fifteen miles distant. The capital is the city of San Salvador, founded in 1528, by George Alvarado. The city was, however, repeatedly destroyed by earthquakes and volcanic eruptions, the last time on April 16th, 1854. The inhabitants then erected new dwellings on a neighbouring site, at present called Nueva San Salvador. But this new capital again was partly destroyed in 1873, by a series of earthquakes and simultaneous eruptions of the neighbouring Tzalco volcano.

Nicaragua is also rich in volcanoes. The old capital of the republic is the city of Leon, some ten miles from the Pacific, surrounded by five active volcanoes, and partly in ruins. At present the seat of the Government is the town of Managua, situated on the southern border of the great lake of the same name. This town is but provisional, being built on the slope of an active volcano, and liable therefore to instant destruction.

No doubt these two countries will open a splendid field for the study of earth currents.

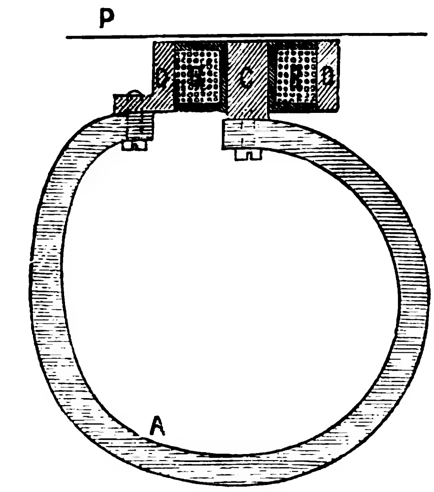
A NEW RED SEA CABLE.—The ss. *Rochefort* was to leave the works of Messrs. Siemens Brothers, on Wednesday, the 26th inst., with the above cable. The contract was made on account of the Turkish Administration of Telegraphs. The length is about 200 nautical miles, and it will be laid from Jeddah, in Turkey, to Souakim, in Egypt. The cable is somewhat similar in type to that of the Black Sea cable of the Eastern Company.

TELEGRAPHIC COMMUNICATION WITH INDIA.—A letter from Colonel F. Burnaby appeared in one of last week's issues of the *Times*, calling attention to the fact, "that in the event of our relations with the Porte being broken off England's telegraphic line of communication with her greatest possession—Hindostan—would be liable at any moment to be cut. Passing, as the wires do, one through Constantinople and Bushore, another through Odessa and Teheran, and the remainder *via* the Delta and India, we are practically dependent upon our friendly relations with the Mahomedan States for our electric communications with Hindostan. The Cape of Good Hope is united by wire with Aden and Bombay; Lisbon is connected with Cape de Verde. Would it not be wise without delay to continue that line through St. Helena to the Cape, thus making us independent of any hostile Mahomedan combination?" In the House of Commons on Friday week, Mr. Leigh asked the Postmaster-General if his attention had been directed to the above letter and if he would take steps to carry out the suggestion and so put our communication beyond the control of hostile Mahomedans? Mr. Fawcett, in answering, stated that the submarine ocean telegraphs are not under the control of the Post-office; that the question forms one of general policy, and that he scarcely felt competent to reply.

THE HOUSE OF COMMONS AND THE TELEPHONE.—In the House of Commons on Thursday week Mr. Shaw-Lefevre, in reply to an interrogation, stated that he would endeavour during the recess to place the House of Commons in telephonic communication with the Telephone Exchange. The only difficulty to encounter was the getting of a suitable room.

M. A. D'ARSONVAL'S TELEPHONE, WITH CIRCULAR MAGNETIC FIELD.—This new form of magnetic telephone was presented by the inventor at the last sitting of the French Physical Society on the 21st of July. M. d'Arsonval was led to adopt this arrangement by studying the effect produced by a wire traversed by an electric current on a double pole telephone (of the Gower, Siemens, or Ader type), without coils. Placing the wire in every position between the poles, internally, laterally, &c., he found as might be expected, that the maximum of effect is obtained when the wire is in that position where the magnetic field is greatest, *i.e.*, between the two poles of the magnet. It is in order to increase the useful part of the wire, which is placed between the arms of the magnet, that the Gower and Ader telephones are furnished with flattened poles. M. d'Arsonval asked himself whether, with a suitable method of coiling, it would not be possible to suppress entirely the outer part of the wire, which introduces into the circuit a supplementary resistance without much useful effect of importance. He effected this by constructing a telephone

with circular magnetic field, similar to Nicklés' electro-magnets. The apparatus shown in the accompanying diagram resembles in its outward form an Ader telephone. The bent magnet, A, forms a handle; on one of the poles is fixed a cylindrical core, C, of soft iron, on the other a ring of soft iron, D, enclosing the first; the coil, B, is placed in the annular space which is left free between these two circular poles. The magnetic field is thus concentrated into the space occupied by the coil, and the lines of force are turned into a direction perpendicular to the wire of the coil. When the telephone is employed as a transmitter, the movements of the plate, P, produce a sort of pivoting



of the lines of force, which gives rise to induction currents. When the telephone is employed as a receiver the undulatory currents which traverse the coil produce a maximum of effect, since they act in that part where the magnetic field is most intense; the modification which they bring to bear on the continuation of the lines of force re-act upon the plate and make it vibrate. With much less weight and a much shorter wire—M. d'Arsonval's telephone weighs 125 grammes, and has only 20 ohms of resistance—we obtain effects as powerful as those produced by the Gower telephone, but with more clearness.

The Gower telephone being furnished with an ear-piece, produces a sound like that heard in a sea-shell, which M. d'Arsonval attributes partly to the too great diameter of the tube and partly to the spiral of metallic wire placed in the tube in order to prevent its becoming flattened. M. d'Arsonval has obviated this difficulty by using a simple tube of gutta-percha eight millimetres (one-third of an inch) in diameter, and thus all resonance is destroyed. It is advantageous in practice to arrange a double tube, one for speaking and the other for hearing.

FRENCH PHYSICAL SOCIETY.—The last sitting of the season took place on Friday, July 21st. The meetings are adjourned during the vacation to November next.

SPECIAL ANNOUNCEMENTS.—We desire to call the attention of our readers to several special announcements at page 10 of supplement.

NEW COMPANY REGISTERED.

ELECTRICAL APPLIANCES SYNDICATE, LIMITED.—Capital £5,000, in £10 shares, with power to increase to £20,000. Objects: To carry on the business of mechanical and electrical engineers and boiler manufacturers of an electric light and power company. Signatories (with one share each): W. Harman, 99, Gresham House; R. Jenkin, 25, Bond Street, Vauxhall; G. S. Ullathorne, C.E., 1, Rutland Road, Hammersmith; S. Crosse, 49, Holland Road, Brixton; R. Soutter, Richmond; H. T. Turner, 106, Vauxhall Bridge Road; H. Ponché, 3, Wilmington Square, W.C. The signatories are to nominate the first directors. Qualification, £100 of share capital. Registered 19th inst. by A. S. Ramskill, 7, Union Court, Old Broad Street.

NEW PATENTS—1882.

3430. "Application of telephones or microphones to pipes or vessels containing and conveying liquids, fluids, gases, and air, for the purpose of detecting leakage therefrom." A. Q. ROSE. (Communicated by F. J. Bell.) Dated July 19.

3433. "Means of operating microphones." P. M. JUSTICE. (Communicated by F. van Rysselberghe.) Dated July 19.

3434. "Electric meters." C. V. BOYS. Dated July 19.

3441. "Apparatus for regulating electric lamps and for measuring electrical currents and electrical energy." A. and F. GRAY. Dated July 20.

3443. "An improved medical battery." W. R. WARREN. (Communicated by G. M. Hopkins.) Dated July 20. *Complete.*

3455. "Dynamo and magneto-electric machinery." J. S. BEEMAN. Dated July 20.

3458. "Telephonic apparatus." J. E. CHASTER. Dated July 20.

3464. "Improvements in secondary batteries or in apparatus for storing electricity." J. H. JOHNSON. (Communicated by J. H. Sutton.) Dated July 21.

3465. "Accumulation and distribution of electricity." L. H. M. SOMZÉE. Dated July 21.

3466. "Improvements in the means or apparatus for generating electric currents and producing motion by electricity, and for regulating electric currents and making and breaking circuits." C. A. CARUS-WILSON. Dated July 21.

3473. "Apparatus for generating, utilising, and regulating electric currents for lighting and other purposes." A. RECKENZAUN. Dated July 21.

3476. "Chambers and receptacles for electrical apparatus." W. A. BARLOW. (Communicated by L. Encausse.) Dated July 21.

3485. "A new or improved method of and apparatus for telegraphing to and from a railway train in motion." W. B. HEALEY. (Communicated by W. L. Hunt.) Dated July 22.

3504. "A new or improved machine for generating electricity." A. D'ORELI. Dated July 24.

3508. "Electric lamp." A. M. CLARK. (Communicated by H. J. Müller and A. Levett.) Dated July 24.

3510. "Means and apparatus for obtaining motive power by electricity." J. BARLOW. Dated July 24.

3513. "Telephones." S. BIDWELL. Dated July 25.

3515. "Distributing and diffusing powerful lights." A. P. Trotter. Dated July 25.

3520. "Arc electric lamps." A. L. LINEFF. Dated July 25.

3528. "Secondary batteries, or storage batteries, and method of, and means for, charging and discharging the same." C. E. BUELL. Dated July 25.

3532. "Secondary or polarisation batteries for the storage of electrical energy." G. L. WINCH. Dated July 25.

3534. "Dynamo-electric machines, or electric generators, and electro motors." O. W. F. HILL. Dated July 25.

3544. "An improved electric regulator and meter." W. LAING. Dated July 26.

3547. "Electric cables." J. G. LORRAIN. (Communicated by J. André.) Dated July 26.

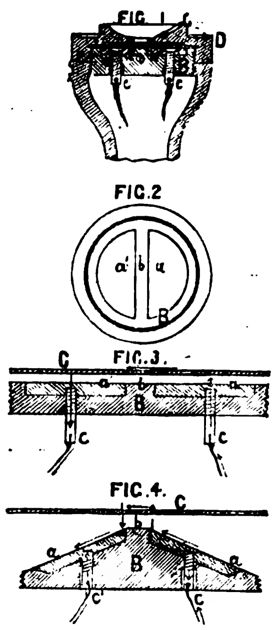
ABSTRACTS OF PUBLISHED SPECIFICATIONS, 1881.

5407. "Manufacture of compounds for electrical insulation." W. ABBOTT and F. FIELD. Dated December 10. 2d. The insulating compound of ozokerit and india-rubber, prepared according to Field and Talling's Patent, No. 1938, of 1875, has the disadvantage of being more or less soft, and therefore not suitable for all purposes. Attempts have been made to vulcanise this compound in the ordinary manner, that is to say, by mixing therewith the vulcanising agents, but this process has been found to deteriorate the insulating properties of the compound and to interfere with its applicability for covering wires. Now according to the present invention the inventors produce a perfectly vulcanised covering for telegraph wires and similar purposes, by first covering the wire with the said compound of ozokerit and india-rubber, and then surrounding such covering with a layer of india-rubber with which an excessive quantity of sulphur or other vulcanising agent has been incorporated; the compound covering so prepared is then subjected to heat such as is usually employed for effecting the vulcanising operation, whereby the compound of ozokerit and india-rubber will become thoroughly vulcanised by means of the excess of vulcanising material in the surrounding covering, resulting in the production of an improved insulating covering consisting of a core or inner layer of vulcanised ozokerit and india-rubber compound surrounded by an outer covering of vulcanised india-rubber. (*Provisional only.*)

5418. "Arrangement of electrical apparatus on railway trains." J. E. LIARDET and T. DONNITHORNE. Dated December 10. 6d. Relates to the arrangement of electrical apparatus on railway trains. The inventors mount dynamo-electric machines upon railway carriages in such manner that the said machines can be set in motion when the train is at a suitable speed and then made to generate electricity, which is stored in secondary batteries and applied when required for lighting the train for signal lights and for propulsion where desired.

5430. "Telephones." A. W. ROSE. Dated December 12. 4d. Consists in the employment of a compound diaphragm, the central portion of which is made of a thin material, and the outer portion of a comparatively thick material, by which is obtained a more effective action of the diaphragm, the thinner portion first yielding to the full extent allowed by its elasticity, and then evoking the action of the thicker portion, which then comes into play, and co-operates with the thinner portion of the compound diaphragm.

5431. "Telephones." A. W. ROSE. Dated December 12. 6d. Relates to the receivers of telephones of that class in which articulate sounds are received by disturbing the statical charge of a circuit. One mode of constructing receivers of this description has been to fit two plates or diaphragms at a short distance from each other, in a suitable case, one of such plates being connected with the secondary coil of an induction coil, and the other plate with earth. According to the present invention, the inventor employs a rigid disc, divided into two parts, which are separated by insulating material, and he connects one half of the disc with the secondary wire of an induction coil, and the other half with earth, or with a return wire, when metallic circuits are used. Opposite this divided disc is a metal diaphragm, secured at its edges, and arranged at a short distance from the disc. The secondary current passes from line to one half of the disc across to the diaphragm, and back to the other half of the disc, and thence to earth, or to the return wire, as the case may be. By this means two positive semi-vibrations of the diaphragm are obtained for each electric pulsation, and thus a louder and better articulation from the receiver is obtained. Fig. 1 represents a section



of a telephonic receiver constructed according to the said invention. Fig. 2 is a plan of the same, with the mouthpiece removed. Fig. 3 is a diagram sectional view, drawn to an enlarged scale, illustrating the direction of the electric current. In figs. 3 and 4 the distance between the divided disc and diaphragm is exaggerated, for the sake of clearness of illustration. a a^1 are two rigid half discs of conducting material, which are separated by an insulating strip, b, the latter being either formed in one, with a carrier-piece, B, of non-conducting material, as shown, or attached to the said carrier piece. One of the half-discs, say, for example, the half, a, is connected with the secondary wire of an indication coil by a terminal, c, and the other half-disc, a^1, is connected by a terminal, c^1, with earth, or with a return wire, when metallic circuits are used. Opposite the two half discs, a a^1, is a metal diaphragm, C, secured at its edges by the mouthpiece, D, so as to be situate in very close proximity to the half discs, a, a^1, without being in actual contact. The secondary current passes from the line to the half disc, a (*see* fig. 3) across to the diaphragm, C, and back to the half disc, a^1, and thence to earth, or to the return wire, as the case may be.

5432. "Telephones." A. W. ROSE. Dated December 12. 4d. Relates first to the microphonic transmitter of telephones and consists in the combination with the compound microphone of a thin vibrating diaphragm of mica or other suitable material. The whole of the carbon buttons of the microphone may be placed in contact with this diaphragm, or the central carbon button only may be in contact with the diaphragm, the surrounding carbon buttons being in contact with the frame. When the diaphragm is composed of iron or other conducting material, it should be insulated from the microphone. By the use of a thin vibrating diaphragm in substitution for the rigid wooden board ordinarily employed, the instrument is rendered more sensitive and the strength of the articulations produced at the receiver is greatly increased.

5445. "Galvanic batteries, &c." O. C. D. ROSS. Dated December 13. 4d. Relates to improvements in galvanic batteries and to the application of such batteries to those electric lamps in which the light is produced in a vacuum glass by the incandescence of a continuous carbon conductor or bridge, and the principal object of the invention is to facilitate the use of the recently invented incandescent lamps by a reduced expenditure on plant and in places and circumstances, such as arise in country mansions, &c., and other places where the lamps cannot advantageously be supplied with electricity by the employment of dynamo electric machines or from secondary storage batteries (Faure's accumulators), which have hitherto been generally considered as the only ways of utilising them. The first part of the invention consists in the construction of a battery occupying but little space, which is very economical and, at the same time, of great power and permanency. The negative and positive elements are platinised broken carbon and amalgamated zinc, which latter is prepared in a comminuted form by pouring it when in a molten condition into water and afterwards amalgamating it in a solution of mercury. Sometimes one or the other of these elements is used in the ordinary form, that is to say, the comminuted zinc is connected with a plate or rod of carbon, or the platinised broken carbon connected with a rod of zinc; and, instead of the ordinary separate cells, a number of cells are combined in a larger vessel, which may be round or square, in which the cells are formed by means of partition slabs, which should be of porous and of impermeable material alternately, or of either of these materials alone. The second part of the invention consists in the combination of galvanic batteries with the above described incandescent lamps, when fitted upon such stems or supporters as will allow of their being shifted about as reading lamps, or of being used as ornamental drawing, or dining room, or hall lamps, or as shop lamps. Any kind of galvanic battery may be employed, but especially such batteries as above named, and batteries in which chromate or bichromate of potash forms the main basis of the solution used to excite either of the zinc and carbon elements. The third part of the invention consists in an arrangement of the vacuum incandescent lamps on their stands, which will allow of their being occasionally taken from the stand and moved from place to place and to a short distance without extinguishing the light. This is effected by attaching a sufficient length of flexible insulated wire between the vacuum glass and the battery, to allow of such removal taking place without interfering with the continuous current of electricity.

5451. "Secondary batteries." J. PITKIN. Dated December 13. 6d. Relates to improvements in secondary batteries or accumulators, and its object is to enable a greater amount of energy to be stored in, and consequently a greater quantity of electricity to be furnished by, electrodes of given dimensions, and at the same time to greatly decrease the weight of the electrodes as compared with that of those formed of plates of lead as usually employed in batteries of this description. The invention consists in forming the electrodes of a mass of very thin turnings or shavings of lead or strips, shreds, or pieces of lead foil or highly laminated sheets of lead in a crumpled condition packed in suitable open frames, preferably of wood or ebonite, and each having a covering of felt, flannel, or other suitable porous material stretched over it on each side to retain the lead in place and allow it to be acted on by the acidulated liquid in which the electrode is immersed.

5452. "Apparatus used in connection with electrical batteries for charging the same, &c." W. R. LAKE. (A communication from abroad by J. F. Aymonnet, of Paris.) Dated December 13. 8d. Relates to apparatus for charging and discharging the liquids in batteries.

5468. "Telegraph or telephone conductors." J. IMRAY. (A communication from abroad by J. M. Stearns, junr., of Brooklyn, America.) Dated December 14. 4d. Relates to the construction and arrangement of cables or grouped conductors for telegraphs or telephones, in such a manner as to prevent the interferences resulting from induction which the passage of an electric current along any one of the group causes in others of the group lying closely adjacent to it. For this purpose a thin sheet of metal, such as copper, having high conductivity, is folded up along with the insulated conductors in a zigzag manner, so that portions of this metal are everywhere interposed between each insulated conductor and those next to it. This metal sheet being at numerous points connected electrically to earth or other discharging conductor, or to the metal pipe in which such cables are often inclosed, carries off induced currents, so that the passage of electricity through any of the grouped conductors does not induce currents in others of the group. Sometimes the insulated conductors are carried in parallel lines along the wall; in such a case the metal sheet can be folded to and fro and passed either in single or in double folds between each adjacent pair and partly round each, and finally over the whole. When the conductors are grouped so as to form a cable, the sheet can in like manner be so undulated or zigzagged as to form a series of loops, each inclosing one of the conductors, which is thus separated by metal from those adjacent to it.

5470. "Galvanic batteries." C. MAURIS. (A communication from abroad by Achille Thomas of Nantes). Dated December 14. 2d. Has for its object improvements in galvanic batteries. The elements of the battery are of zinc and carbon or it might be of copper or other electro negative metal. Their form is that of semicircular discs and they (especially the zinc elements) are perforated with numerous holes to increase the area of the surfaces exposed to electro chemical action. The elements are fixed upon an axis from which they are electrically insulated. This axis passes longitudinally through a box or case which is divided interiorly into cells by a number of partitions extending from the bottom up to the axis. Each cell receives two zincs and one carbon or electro-negative element. The box is lined with bituminous cement or otherwise so as to render it water tight. Within each cell or compartment of the box there is a vessel of porous earthenware, into which the carbon or negative element is received, and this vessel has a cover which may be of glazed earthenware. The negative elements are thus enclosed each within its porous vessel and its cover and there is room in the enclosure to permit of the axis turning and carrying the elements round with it. The lower part of the box is charged with sawdust saturated with water acidulated with sulphuric acid. This is in contact with the zincs.

5481. "Secondary batteries." DESMOND GERALD FITZ-GERALD. Dated December 14. 4d. Consists in the use of carbon in conjunction

with lead or compounds of lead, for the electrodes of secondary batteries. In carrying the invention into effect the inventor constructs plates of carbon with perforations, grooves, or recesses which are filled with lead, preferably in a state of fine division, or with any suitable compound of lead. The pores of the carbon also are filled with the same material, which in this case more especially may advantageously be produced by the decomposition of a salt or of an oxide of lead.

5490. "Electric lamps." W. R. LAKE. (A communication from abroad by Jean Auguste Mondos, of Neuilly, France.) Dated December 15. 6d. Relates to electric lamps of that class in which no clockwork is employed for controlling the movement of the carbons, the electric current being utilised for effecting this movement. According to this invention two successive movements are imparted to the carbons, the first being a sudden movement which separates the carbons and causes the electric arc to be developed, and the other a movement which takes place in proportion to the wear of the carbons and maintains them at the proper distance from each other.

5494. "Secondary voltaic cells." J. W. SWAN. Dated December 15. 2d. Has for its object the preparation of lead plates, to be used in the construction of cells for secondary batteries upon the principle proposed by Planté, with a view to diminish the time usually occupied in their preparation. In carrying out the invention, the inventor takes plates of lead of any suitable form, but preferably corrugated, grooved or cellular plates as described in specification 2272, dated May 24, 1881, and exposes them to the combined action of acetic acid, carbonic acid, and atmospheric air, as in the well-known process of making white lead; which action results in the formation of carbonate of lead on the lead plates. This formation may extend to a depth greater or less according to the time such plates are subjected to the vapours and gases. After this action has taken place to a sufficient depth, a portion of the plate being generally allowed to remain unacted upon, the inventor subjects the treated plates to the action of electrolytic hydrogen by making them the cathode of an electric generator (which may either be a voltaic battery, a dynamo or magneto-electric machine, a thermopile or any other suitable electricity generator in a suitable electrolyte). When the carbonate of lead has been transformed into metallic lead by the said electrolytic action, the plates so treated are used in the well-known manner of arranging and using lead plates in the construction and charging and use of Planté secondary cells.

5499. "Measuring and recording electric currents." J. W. SWAN. Dated December 16. 4d. In the patent dated December 1, 1880, No. 5004, the inventor described an electric meter intended chiefly to be used in connection with electric lamps. The apparatus described in the said specification is so constructed that it is necessary to have a pair of wires extending between the meter and each of the lamps. The present invention is in part an improvement in that apparatus, the improvement consisting in the avoidance of the branch wires from individual lamps. The inventor accomplishes this object by taking the main conducting wire, or a shunt from it, round the several electro-magnets, which determine the engagement or disengagement of the intermediate pawls with the counting mechanism and adjusts the springs which counteract the pull of these electro-magnets, so that when the current for the supply of one lamp is passing through the main wire or shunt only one of the magnet armatures will be attracted from its inactive position, and when current is passing for the supply of more than one lamp the number of magnet armatures rendered operative shall correspond with the number of lamps lighted.

5521. "Secondary or polarisation batteries for storage of electric energy." G. GROUT and W. H. JONES. Dated December 17. 4d. The first part of this invention relates to a preparation or combination of lead or other metal with carbon prepared, as hereafter described, to construct the elements of secondary or polarisation batteries for the storage of electric energy. The second part relates to the application of metallic lead dust to be used to cover, to heap around, or compress upon, the blades or plates of whatever nature used as the core or conductor of the elements of these batteries.

5536. "Dynamo-electric machines." J. E. H. GORDON. Dated December 17. 6d. Relates to improvements in dynamo machines and particularly in that described by the inventor in specification No. 78, 1881. In the machine described in that specification the revolving rings each carry the same number of magnet coils as the fixed rings carry armature coils, the drawings annexed to the specification show them as each carrying 16 coils. The armature coils were also made cylindrical and of the same diameter as the magnets, each being placed close to the next. The inventor has found that these coils act on each other by mutual induction in a very injurious manner during the working of the machine. If a certain number of lamps are being maintained by one coil, closing the circuit of the next to it on one side reduces the light of the lamps on the first by some 20 or 30 per cent.; closing the circuit of the next of the other side still further reduces it by a like amount. The reason is that as the currents in contiguous coils circulate in opposite directions they are in the same direction in those parts of the two coils which are immediately contiguous to each other. As the currents in the two coils are both increasing at the same time they retard each other by their mutual action. In the arrangement of the machine which is the subject of the present patent, this drawback is got rid of by making the number of armature coils twice the number of the magnet coils. The magnets therefore act alternately on the alternate set of coils.

5542. "Galvanic battery." W. R. LAKE. (A communication from abroad by La Société Universelle d'Electricité Tommasi, of Paris.) Dated December 17. 6d. Has for its object an improved galvanic battery which is advantageous as compared with other batteries in respect of its small volume, its great effective surface, and its slight internal resistance. The said improved battery works with one liquid only, the copper and zinc elements are separated by a porous diaphragm, and the jar or vessel which encloses the elements of the battery contains crystals of sulphate of copper; it therefore belongs to the same class as that known as the "Daniell" battery. The invention is based essentially upon two features; that is to say, one feature is the employment of the zinc and copper metals in the form of wires, having a diameter of about 5 to 7 millimetres, twisted spirally or arranged in parallel lines, joined by curves or rounded parts when the vessel used is of square or rectangular form. One extremity of these wires protrudes outside of the said vessel and is bent horizontally to be directly coupled to the corresponding wires of the other elements in order to constitute a battery, which thus can be made up to any quantity and tension desired. The other feature is the replacing of the porous cylinder or vase generally used in the construction of the "Daniell" battery by a sheet of parchment or dyalised paper, arranged horizontally, and the edges of which are plaited or folded, and rise above the level of the liquid contained in the aforesaid jar or vessel.

5551. "Armatures for magneto-electric, &c., machines, &c." J. H. JOHNSON. (A communication from abroad by William Woodnutt Griscom, of Philadelphia.) Dated December 19. 6d. Has especial reference to armatures of the type known as Siemens' armatures, but it is applicable to the poles of all other magnets or armatures, and it consists in dividing the bi-polar extremities of such armatures into two or more sections concentric with each other, one or more of such sections being at such a distance as to utilise the magnetic lines of force which fill the space between the two poles of the field-magnets whilst the other section or sections are arranged so as to pass in close proximity to the poles of the field-magnets and thus utilise the powerful attraction between the poles of the armature and magnet as the one approaches the other. Figs. 1 and 2 represent a transverse section of a magneto-electric dynamo or electro-magnetic armature and a field-magnet respectively constructed according to the said invention. Referring to fig. 1, A is an armature of the

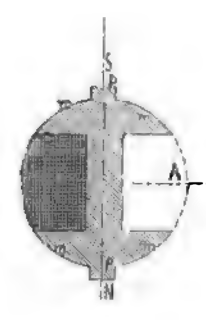


FIG. 1.

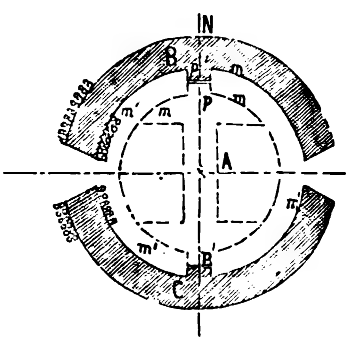

FIG. 2.

before-mentioned type having its bi-polar extremities divided into two or more sections concentric with each other, one or more of such section, *m*, revolving or working at such a distance within the field-magnets, B and C (*see* fig. 2), so as to utilise the magnetic lines of force which are generated and disseminated in the magnetic field or space between the two poles of the aforesaid magnets. The other section or sections, *p*, before referred to, are longitudinal ribs or projections concentric with, but extending or protruding above or beyond, the peripheries of the other sections, *m*, so as to pass when the armature is revolving, in closer proximity to the poles of the field-magnets, B and C, than do the said sections, *m*, so as to economically utilise the lines of magnetic force between the poles of the field-magnet. The interior surfaces of the field-magnets, B and C, are formed or provided with projecting ribs or pieces, p^1, arranged so as just to clear the projections, *p*, upon the armature, A, when it is revolving. In this manner the poles, p p^1, are caused to utilise certain magneto- or electro-inductive influences upon the extremely close approach of iron to iron, while the polar surfaces, m m^1, are arranged for utilising the induced lines of force extending across the magnetic field of the magnets, B and C.

5566. "Producing electric currents." ADAM MILLAR. Dated December 20. 2d. Relates to improvements in apparatus for producing electric currents, and consists in arrangements for utilising the inductive action which a magnet has upon a conductor forming part of a closed circuit and placed in one part of the magnetic field of the magnet, whenever the magnetism of the magnet is made to vary in intensity by the action in another part of the magnetic field of an armature or another magnet, or of a conductor carrying a current, or of any other body which increases or diminishes the magnetism of the magnet. (*Void by reason of the patentee having neglected to file a specification in pursuance of the conditions of the letters patent.*)

5573. "Telephones and telegraphs." W. R. LAKE. (A communication from abroad by J. H. Rogers, of America.) Dated December 20. 8d. Relates to a method of secret telephony, or telegraphy, in which two or more circuits are used in such a manner that any one tapping but one of the circuits is unable to obtain anything but a confused and unintelligible series of signals. The said invention also relates to apparatus employed in carrying this method into effect. The said invention is partly based upon the use of an interrupted current as distinguished from a pulsatory current. According to this invention the inventor passes a message sent from any transmitting instrument through two or more circuits alternately in rapid succession. A receiver is placed in each circuit so that the two receivers together give a continuous series of signals, the one supplying what the other omits. The current conveying the message is thrown alternately on each circuit by means of a circuit-breaker which makes and breaks contact with each circuit in succession.

5593. "Dynamo-electric machines." L. S. POWELL. (A communication from abroad by Jean Marie Anatole Gérard Lescuyer

Paris.) Dated December 21. 6d. Relates to dynamo-electric machines and it consists in certain improvements in their construction and arrangement. In carrying out this invention, the improved dynamo-electric machine is constructed with a movable inducing part formed by a wheel, say, for example, of brass or gun metal, which is keyed upon a shaft mounted in suitable bearings. A certain number of straight electro-magnets are arranged on the circumference of this wheel in such a manner as to present alternate north and south poles on each side of the wheel. These electro-magnets are connected with a collector on the shaft of the machine communicating through rubbers or brushes with a machine generating direct or continuous currents. The induced part is fixed or stationary, and consists of two series of oval or elliptical coils attached to two rings or frames of iron or copper placed on each side of the inductor. The wire in these coils is wound between two elliptical plates or cheeks connected together by two iron connecting bars and a copper bolt which serves to attach the coils to the rings. The connecting bars nearest to the centre of the machine are preferably angular in cross section and the bars nearest to the outer extremity of the cheeks are preferably circular in section and somewhat thicker than the angular bars. The wire is wound upon these bars in the space between the cheeks. The cheeks facing the inductors or revolving magnets are perforated with a number of holes; but the cheeks which face the rings or frame are imperforated. A thin sheet of metal is interposed between each layer of wire in the coils in order to assist the inducing action and prevent the formation of extra currents. The currents generated in the coils by the passage of the inducting electro-magnets are alternate and may be used separately or may be combined by means of a commutator.

5595. "Electric calls for telephones, &c." A. W. LAKE. (A communication from abroad by W. C. Lockwood, of Brooklyn, America.) Dated December 21. 6d. Relates to telephone calls. In this invention the operating call winds up a spring mechanism.

5599. "Insulated conductors for telegraphic uses, &c." WILLOUGHBY SMITH. Dated December 21. 2d. Has for its object improvements in insulated conductors for telegraphic and other uses. The insulated conductors now used in submarine, subterranean, and other telegraphs consist for the most part of copper wire covered with gutta-percha, and the gutta-percha is used in as pure a state as it can be obtained. Now for this pure material, which is expensive, the inventor substitutes a compound of gutta percha with zinc white.

5604. "Galvanic batteries for electric lighting, &c." E. B. BURR and W. T. SCOTT. Dated December 22. 6d. Has for its object improvements in galvanic batteries for electric lighting and for other purposes. The improved galvanic battery consists of zinc and carbon elements arranged in cells made of wood lined with waterproof cement. The cells are filled around the elements with asbestos fibre, blown slag, or like material, and this is saturated with a mixture of bichromate of potash and phosphoric acid with a little nitric acid added.

5615. "Cables for telephonic and telegraphic communication." J. N. CULBERTSON and J. W. BROWN. Dated December 22. 6d. Has for its object improvements in the construction of cables or collections of metallic conductors for telephonic and telegraphic communication. According to the present invention the inventors employ pipes made in convenient lengths and with perforated insulating discs at each end. The wires in similar lengths are threaded through these discs and such other intermediate insulating discs as it may be convenient to employ and are strained tight.

5623. "Measuring electric currents." C. A. CARUS-WILSON. Dated December 23. 4d. Relates to means or apparatus for measuring electric currents, and it consists essentially in the employment for this purpose of a secondary battery or secondary batteries which, or each of which, is first charged or acted upon by the current to be measured or a part of it, and is then allowed to discharge or run down or has its current reversed, these alternate actions being repeated and made to communicate motion to or regulate the action of any given counting or integrating apparatus. (*Provisional only.*)

5627. "Electric call signals." H. J. HADDAN. (A communication from abroad by G. W. Foster and F. B. Wilson, both of Paris). Dated December 23. 2d. The improvements consist of clockwork provided with an escapement in combination with a double helix, furnished with a metallic rod, having an armature on one end, said armature being placed directly in front of the helix for the purpose of being attracted towards said helix by passing a current of electricity through the same. The slightest movement of the armature caused by the current being broken releases the escapement and allows the main spring in the clock-work to run down or unwind and in so unwinding causes a hammer connected with the said clock-work to strike a metal gong and give forth a series of taps or a single tap on the gong to attract the attention of any one in the immediate neighbourhood of the instrument. (*Provisional only.*)

5631. "Secondary batteries." J. S. SELLON. Dated December 23. 2d. Relates to the construction of the terminal plates, supports, retainers or frames upon and in which the active material or agent is deposited, placed, or fixed. In carrying out this invention the inventor constructs such plates, supports, retainers, or frames of a material or materials not readily subjected to the destructive influence of oxidation or other destructive action, such, for example, as carbon either in a solid form or compressed or mixed or amalgamated with other substances or as asbestos, wood, papier mâché, cellulose, either alone or in combination with metals not easily oxidised, such, for example, as platinum. The plates, supports, retainers, or frames, composed of one or more of these materials, are constructed in the following or other suitable form or forms. For example, they may be made of a cellular, perforated, corrugated, grooved, fluted, roughened, indented, tubular, or woven shape, or any combination of these forms or of any other shape capable of retaining the active material or agent in a finely divided, pasted, deposited, compressed, or other condition.

CITY NOTES.

OLD BROAD STREET.

THE METROPOLITAN (BRUSH) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

LAST Monday, at noon, an extraordinary general meeting of the members of this company was held at Cannon Street Hotel, Sir Michael Kennedy, R.E., K.C.S.I., presiding, for the purpose of considering, and, if thought advisable, of passing, as a special resolution the following resolution, or a resolution or resolutions to the following effect, that is to say—

"Resolved—That the Articles of Association of the company be, and the same are hereby altered as follows :—

"(I.) By the insertion in Article 4 after the words 'the directors may,' with which it begins, of the words 'with the sanction of a general meeting.'

"(II.) By the alteration in Articles 81 and 89 of '1886,' therein mentioned, to '1884.'

"(III.) By the omission of Articles 85 and 100."

The secretary (Mr. Robt. Wilson) having read the notice convening the meeting,

The Chairman said: We are assembled here to-day for the special purpose of considering, and, if you think advisable, to pass resolutions making alteration in certain of our Articles of Association. These alterations have been dictated to us by the Committee of the Stock Exchange, who, unless we make the necessary alterations, will not grant us a quotation. And it is very desirable that we should have as little delay as possible before getting a quotation, and the only difficulty which now lies in our way is that which we have met here to-day to overcome. A very few words from me are requisite to make you acquainted with the nature and the scope of the desired alterations. The first is in clause 4 of the Articles, and its object is to prevent the directors, without the sanction of a general meeting, issuing shares at a discount. The alterations in Articles 81 and 89 are merely to reduce the time in which the present board holds office from "1886" to "1884." The next alteration is the omission altogether of clause 85 of the Articles, and the object of that is to secure that all matters of importance which may require the consideration of a general meeting should be discussed in a general meeting, and not be settled by correspondence; the arrangement in the expunging of Article 100 is somewhat similar—to enable matters to be settled by the board and not settled by correspondence. I trust the resolutions to be submitted will commend themselves to you generally. I therefore beg to move the following resolution :—"(1), Resolved that the following words be inserted at the end of Article 4, 'provided always that no shares shall be issued at a discount without the sanction of a general meeting;' (2), that, in lieu of '1886,' occurring in Articles 81 and 89, respectively, '1884' be inserted; (3), that Articles 85 and 100 be, and hereby are expunged."

Mr. Whitehead in seconding the motion, said it was not necessary for him to detain the meeting with any lengthened observations. It would be clear, he thought, to the shareholders present, that the suggestions made to them by the Committee of the Stock Exchange were in themselves very reasonable. They did not interfere adversely with the value of their property, and they would obtain for them an early settlement and quotation, while immediately enhancing the value of their shares in the market. He was sure the resolution would commend itself.

Mr. Wright asked that the chairman would read Articles 85 and 100 as they now stood; and might he ask also if the board could inform the meeting why it was that the shares which were at a premium in May last of 18s. and 15s., were now at 25s. and 30s. discount.

The Chairman having read the articles referred to, said that, as regarded the price of the shares, he was not able to answer that question. He supposed that the reason why their shares did not stand at the premium they formerly did was because they were purchased by speculators.

Mr. Wright said perhaps he put the question rather vaguely. He thought that perhaps the board had some knowledge or some reason amongst themselves in connection with the character of the work being carried on.

The Chairman: I can emphatically deny that the board have any knowledge of the reason why our shares stand at the present rate.

Mr. A. H. Rolls remarked that the shareholders were a little foggy as to what the operations of the company were, and if the chairman could enlighten them he should be glad.

The Chairman remarked that they had met there that day to discuss a special, and come to a special, resolution. However, he had no hesitation in saying that the prospects of the company were very favourable. They were receiving large numbers of orders, were establishing central stations in different parts of the metropolis, and they expected to do a very good business. This was hardly a meeting in which to discuss the question asked. They believed in the "survival of the fittest," they had a good system and a large field. With the assistance of Mr. Hammond, who sat near him, they were pushing the business, and pushing it with very good success. He could not answer every question particularly, but answering generally he must say that their prospects at the present moment were quite as favourable as they could expect them to be under the circumstances. They had not long commenced, and there had been many a difficulty before them. There was a difficulty as regarded legislation, and there was a difficulty with regard to an accumulator. They had been taking steps for overcoming their difficulties, and when they had had a little more time they would be doing a very good business.

Mr. Bischoff read Article 4, and asked if it were not true that all the shares were not already allotted.

The Chairman replied that the whole of the shares were applied for several times over. The whole were allotted. There are, however, a few still unallotted, because certain gentlemen withdrew.

Mr. Bischoff asked if this alteration in Article 4 was merely to conform with the requirements of the Committee of the Stock Exchange?

The Chairman: Entirely.

In reply to a shareholder, the Chairman stated that the number of shares unallotted at the present time was 310.

In reply to Mr. Thomson, the Chairman said that no shares were allowed to be withdrawn after the allotment except in those cases in which the persons were legally entitled to do so.

The resolutions as previously moved and seconded were then put to the meeting and carried unanimously.

The Chairman: We have now disposed of the special business we met to transact to-day, and our first statutory meeting will be held to confirm those resolutions now passed at the earliest possible moment. That will be within one month from the present. A statutory meeting was to be held within four months of the time of registration.

Dr. Pocock said he would like to call attention to one specially valuable feature of the electric light, which he thought might be advantageously dwelt upon in their prospectus, namely, its use in sick chambers, and so on, where it was of particular importance to have a light that would not vitiate the atmosphere. He had a good deal to do with that as a medical man. It frequently happened that a considerable quantity of gas used in lighting passed away unconsumed. In that respect, as well as in its keeping the air of the chamber cool, he had found the electric light far superior to any other source of illumination with which he was acquainted.

Mr. Hammond said that that special feature of the light was referred to in the prospectus, as it was undoubtedly a great advantage.

The proceedings then terminated.

THE ELECTRIC LIGHTING AND MAINTENANCE COMPANY (LIMITED).

ON Monday afternoon last a numerously attended statutory general meeting of the above company was held in the City Terminus Hotel, Colonel R. R. Jackson presiding in the absence of the chairman of the company, the directors present being Messrs. Sandeman, Pixley, Norman, Lee, Maudslay, and Young.

The secretary, Mr. F. R. Grigg, having read the notice convening the meeting,

The Chairman said: Gentlemen, I very much regret that Mr. Martin Smith, chairman of the company, owing to a very serious domestic bereavement is unable to attend the meeting to-day. The directors regret it the more because Mr. Smith has a very large pecuniary interest in the company, pays great attention to its policy, and has very strong views as to the lines upon which we ought to work. I regret also that the vice-chairman is absent because he is in America. You are aware that this is a statutory meeting of the company—a meeting called under the requirements of the law—and that there is usually no business whatever transacted at a meeting of this character. The directors of course must adhere to that line as regards the transaction of business, but they feel it their duty to explain the course they have pursued hitherto, and the policy they advocate in the future to the shareholders who are present to-day. The directors have not found it expedient to sink the money intrusted to them so far in the erection of electric installations. They have found that there has been a very great change in the position of the electrical world since they issued their prospectus: there has been an enormous number of new companies created, and the manufacturing companies which at that time held the greatest prominence have adopted the policy of the formation of sub-companies. The result is that instead of there being only about half a million at the disposal of electric light companies, as there was when the prospectus was issued, there are about twelve millions of capital at their command supposing the shareholders respond to the calls that may, in the discretion of their directors, be made upon them. One result of this change in the position of affairs has been that there is a very much larger number of companies prepared to erect apparatus in order to give the public the use of the electric light, whilst the manufacturing power is very little increased. Electrical apparatus, therefore, is excessively dear, and its dearness interferes with profitable investment for the purpose of electric illumination. Your directors have, therefore, thought that it would be wiser for the time being to look on and to see whether in process of time electrical apparatus will fall in cost so far as to enable this company to buy on advantageous terms. If not, then the directors of the company would possibly recommend to the shareholders the adoption of the policy foreshadowed in one of the later paragraphs of the prospectus, departing to a certain extent from the line indicated generally as the policy of the company, and to start manufacturing. In certain eventualities that in all probability would be the right policy for the company to adopt. I am happy to be able to inform you that the capital of the company is practically intact. 20,034 shares were allotted, and no portion of the money subscribed has been returned, and making provision for the staff of the company for some time to come, and the rent of its offices and all the expenses incurred, a very small amount per share would meet all the liabilities and expenditure so far as yet incurred by the company. The delay of the company in erecting installations has resulted to a certain extent also from a desire to see what the clauses of the Electric Lighting Bill would be. Now there is one of these clauses which it strikes the directors of this company is calculated very much to retard the progress of the electric light, and to cause it to cost a great deal more than it ought to the general public—I mean that clause which enables public bodies to take over the property of electric companies at the expiration of fifteen years, without giving anything for goodwill, and simply taking the then value of the plant. That seems to me a very absurd provision, because invention as regards the electric lighting is in its infancy. It is very probable that the first apparatus put down may have to be renewed more than once in the course of fifteen years, and if the electric light companies are to charge the public for the use of the light in proportion to the risks run and the expense incurred, the charges must be so great as to prevent the use of the electric light by the general public. The Bill, therefore, seems to be a Bill in its present form which is better calculated to protect the gas companies than aid the development of the new light. I do not think, however, a clause so unjust as that can continue to remain long in the Bill, and I think when the nature of its operations is fully understood by parliament we may reasonably expect that it may be materially altered in the direction of fair play. With reference to the position of the capital of the company, if any questions are asked hereafter, I shall be prepared to answer them with the utmost care, it being the desire of the directors that there should be nothing whatever under any circumstances withheld from the shareholders. To complete what I think it necessary to say to you now, I beg to state that the directors have not taken, and will not take any remuneration whatever for their services until the shareholders receive a dividend (hear, hear). You are aware, I think, because the terms of the prospectus explain that fact, that the preliminary expenditure has been met by the directors—they doing that in consideration of having allotted to them certain founders' shares, which will only be of value after the shareholders receive 6 per cent. (hear, hear). One other subject I may mention before we listen to the remarks of shareholders: there will be no call made in September.

Mr. Geo. Whitley said that the first issue was quoted at one million sterling, and, as an addition, there were £3,000 of what they called founders' shares. Only £200,000 was subscribed. He would like to ask if they thought it quite fair that these £3,000 should be charged to the small fraction of what was originally intended to be £1,000,000.

The Chairman said that he thought the answer to Mr. Whitley's question a very simple one. On the present subscription of £200,000, the profit on the founders' shares was one-third of the profit which would remain after the payment of 6 per cent. If there was no business done there would be nothing to receive, and therefore these shares would be no burden upon the issue. They were issued as fully paid up, and there would be no interest to them in the business of the company until the shareholders received 6 per cent.

Mr. Porter said that the directors wished apparently to give them a clear statement of the position of the company, and the chairman had certainly done so. When the prospectus was originally issued it was supposed that it was proposed to call one million up, and keep it profitably employed. That was at the commencement of the Easter holidays, but the lists were suddenly closed when only £200,000 was collected, and in a circular issued on the 8th April it was stated that the reason of closing the lists was that it was desirable to commence operations at once. They now learned, however, that that was not the case, that nothing had been done within the past three months, that on the contrary the prospect of getting work was very much worse now than it was at that time, because those parent companies, if they might so call them, had given monopolies to subsidiary companies, and therefore an independent company like their own had no apparent prospect of profitable work left. He therefore thought that the question at the present time—though he was merely expressing his own private opinion, having had no conversation on the matter with other shareholders—was whether under the circumstances he had mentioned it was desirable to keep the company going. Whether it would not be better to wind up the company at once. He did not say that in any hostile spirit to the directors. They had done their best, and had the capital still intact, and it had been also stated that they did not wish to receive any remuneration until the company had received a dividend. Nothing could be more fair and straightforward (hear, hear); but still he thought it was still a question whether the reasons he had given did not make it desirable to close the company.

Mr. W. H. Maturin was a little disappointed at the position held by the company and at their not being able to carry out their plans, but he was not surprised at it, the prospect had been so very uncertain, the policy the directors had shadowed out was a very judicious and prudent one, to keep the capital safe in their hands, and not to use it till they could do so advantageously, and only then, as far as they could, with the knowledge and consent of the shareholders. That was a very satisfactory thing for them to consider, and there was another satisfactory thing that the gentlemen connected with the company did not intend to draw any remuneration until the company was a paying concern. He was also glad that they had kept the expenses down to a minimum.

The Chairman said he might add that in regard to the expenses what he wished to convey was that a very small amount per share would meet the expenses already incurred, not that it was their intention to make a call for that purpose.

Mr. Maturin would like to know what amount of money was paid up.

The Chairman said that the amount was £39,918.

Mr. Maturin said he supposed that they were then deriving an income from the investment of that sum. That though it was possible their expectations might not be realised, and that the company might have to wind up, his opinion was that that time had not arrived yet. They did not know what might occur a few months hence, and there might be opportunities to make their company a paying concern. He thought the directors were bound not to incur any expenses whatever beyond what might be paid out of the interest of the money they had, which, doubtless, if advantageously invested, would yield 3½ to 4 per cent. That being the case, and the shareholders knowing that they were incurring no further liabilities, and that their money was perfectly safe in the hands of the directors, they should simply hold it in trust

to see whether a good time would come for employing it. He believed that it was better not to speak of winding up the company, but to leave that to the directors to bring before them at some future time.

Mr. W. Thomson asked if it was a fact that money was returned to any subscribers to shares, on allotment, or at any other time, and if so why was it so returned?

The Chairman said that the simple answer to that was that no money had been returned.

Dr. W. Pocock said that a waiting policy in an affair of this kind which required to be developed and which in the meantime was more or less arrested in its development, showed that the directors had been actuated by a very satisfactory judgment of the position of the company, and he believed the policy was one which recommended itself to all thinking men. The fact of the company not having called up a large amount of capital was an evidence of some doubt in the minds of the board as to the advisability of the course entered upon. They should bear in mind that they were crippled at the outset by legislative proceedings, which had been referred to, which, however, would scarcely stand the light of a very long period without being reversed or at least altered. He believed the policy adopted was the resultant of a very great deal of quiet thought and careful judgment on the part of the directors in the exercise of their functions. They should trust them for the future, and give them support in the careful policy which they had initiated.

Mr. Richard Wilson said that when the company was started a prospectus was issued which invited subscriptions to the amount of £1,000,000, and a statement was subsequently issued that only one-fifth of that had been subscribed. Under ordinary circumstances, when a large sum was invited to be subscribed by the public and it was found that only a small subscription was made, the directors did not usually proceed to the allotment of the shares; and he confessed that when he received the paper stating that the shares had been allotted, he was very much surprised at that departure from the ordinary proceeding in such cases. He quite agreed that it would be better to return the capital.

The Chairman said that the directors would be largely guided by what they found to be the general wish of the body of the shareholders.

Mr. Whitley said that in the original prospectus the objects of the company were put in the forefront as electric lighting and maintenance, and it was a question with him how far they were justified in leaving these and embarking in manufacturing, which was only found at the tail of the articles of association. The main conditions of these articles were now proposed to be left out, and they were going to manufacture and trade on the strength of a little article at the very end of the memoranda of association. He did not think that was fair. The main objects of the company were to have the electric light laid on wherever it was required, and if that failed the object of the company failed to, and it would be far better to wind it up and start a new company for manufacturing.

The Chairman: Gentlemen, I think the shareholders have been extremely fair in the expression of their opinion upon the subject which has been before the meeting. Mr. Porter's remarks were very much to the point. It might be thought, if there was no immediate means of finding profitable employment for the money of the company it would be wiser to return it. It was however thought, as was expressed by Mr. Maturin, that it was better to wait and watch the progress of events for awhile, and see if the policy upon which the company originally was formed was not the right policy, and if circumstances did not so turn round as to enable the directors to employ your capital profitably. The directors' view is entirely in accordance with that of the second speaker. His expression of opinion was remarkably fair, and there was only one point in it upon which I wish to make any comment in an opposite direction. He said that the directors should limit their expenditure to the interest to be derived from the money in their hands, as nearly as possible. That ought to be so, but it is not quite possible, because it is necessary for us to have a staff, to have a certain number of trained men who are constantly looking out and observing what is going on in the electrical world and reporting it to the directors; and then there is the rent of the premises we occupy now. These expenses will come to somewhat more than the interest of the capital in our hands. The amount that the shareholders are already responsible for covers the salary of the engineer for a year, other salaries for six months, the rent of the premises for a whole year, and if we wait for some time—say, six months—very little additional expenditure will be incurred; so that I for my own part and the directors as a whole, favour the waiting policy. One reason why we did not at once invest your money, as we intended to do, was, that although we were offered a great number of installations, and might have invested a great deal of money, when we came to examine the probable result, we did not feel justified in accepting them because there was no adequate profit. That was a disappointment to the directors, but they explained the fact to themselves, as it has been explained to you to-day, and they think there is likely to be a change in the circumstances which will enable them to give the public the benefit of the electric light with advantage to the company and to the shareholders. If it proves not to be so, whatever your resolution to-day, the directors will certainly not risk your money, and would prefer winding up the company. Mr. Whitley, I think, made some observations as to the fact that we asked for a million, and having received £200,000, we still went on with the company. Now I do not see how our receiving applications for £200,000 instead of a million altered our position at all. If our policy was right we could carry it out with £200,000 almost as well as with a million, and if it was wrong then it was better not to have locked up a larger sum of money. So I don't see that the directors were bound when the subscriptions amounted to only one-fifth of what was asked to return the allotment and refuse to proceed with the business of the company. I don't know that any other remarks were made which might require any comments from the chair. The directors are of course gratified by the expressions of confidence in them, to which Mr. Maturin, Dr. Pocock, and others have given expression, and it will be their endeavour under all circumstances to retain the confidence of the shareholders by acting in accordance with their interests. This being a statutory meeting, it is impossible to pass a resolution, but the directors would like to make use of this opportunity which they have of meeting the shareholders to ascertain their opinion in an informal manner upon one or two points. I will ask those who think the policy of winding up the company is preferable to the policy of waiting, to hold up their hands. [Nine hands were held up.] Nine. Those who prefer a waiting policy, which the directors favour, will please hold up theirs. [A great number of hands were held up.] There is a very large majority in favour of waiting. You must recollect that what we are doing is quite informal.

Mr. Whitley asked whether they had any contracts on hand.

The Chairman said they had not.

Mr. Whitley said that if they adopted a waiting policy would they not then be committed to a lot of contracts before their next meeting?

The Chairman said he must ask for the confidence of the shareholders (hear, hear). He would hardly venture to answer that question, because if they were offered installations that would pay they certainly should invest the money of the company in them.

Mr. Porter said that while they were very much indebted for the courteous manner in which the chairman had replied to their queries, he was sorry that the question had been put so hurriedly. He was going to propose a kind of compromise. He thought they were all satisfied to leave their interests in the hands of the board, but it appeared quite clear that the directors admitted being disappointed in the anticipation of obtaining profitable work, but that also it was well to adopt a waiting policy in view of certain circumstances that might arise. The expenses for the next six months would not be so proportionately heavy as they had been in the past, and it was better to hold their hands and see how things turned up. He would, however, suggest that if in the course of three or four months they were still disappointed in their anticipations of obtaining profitable work, a meeting should be called and the question submitted to the shareholders whether under these circumstances they should go on any longer or not (hear, hear).

The Chairman: There is one question with reference to which we should like to have the informal opinion of the shareholders. I explained to you that the directors thought if electrical apparatus could not be got at a moderate percentage on the cost—if they still continued so high—it might be a wise policy on the part of the company to manufacture their own apparatus. I should like to know what the opinion of the shareholders present is upon that subject, and I would ask those who think that under such circumstances it would be desirable to manufacture such apparatus to hold up their hands.

Mr. Porter: Please don't put that. I do not think this meeting ought to deal with that. I think we should leave that in your hands whether you find it profitable or not. We should leave that entirely to the responsibility of the board (hear, hear).

The Chairman: If that is the opinion of the shareholders of course the directors will take upon themselves the responsibility of acting to the best of their judgment, and giving account to the shareholders at the earliest possible moment afterwards. Still, as we have gone out of the region of strict formality, I thought there might be advantage in arriving at your views on that very important subject. I am glad that you have decided that it is the general view of the shareholders present that it is best to leave that subject in the hands of the directors.

Dr. Pocock said that after the clear and satisfactory statement of the chairman there could not be the slightest hesitation in saying that the board was actuated by feelings which would prompt them to consider the shareholders' interests. He thought they decidedly ought to leave the management of their capital in the hands of the directors to use in the best possible way.

The Chairman: Now, gentlemen, we may consider, if you will, the statutory meeting over, and we will become an extraordinary general meeting, for the purpose of considering and, if thought fit, of passing the following resolution: "That the regulations of the company be altered so as to authorise the company so far to modify the conditions contained in its memorandum of association, as by subdivision of its existing shares, to divide its capital or any part thereof into shares of a smaller amount than £10 each, and that thereupon each of the A shares of £10 each comprised in the capital of the company, stated in the memorandum of association, be divided into two A shares of £5 each; and each of the B shares of £10 each, comprised in the said capital, be divided into two B shares of £5 each." That was a suggestion made to us during the progress of the formation of the company, and it was suggested there would be some advantage in having a £5 rather than a £10 share. I must, however, inform you that that change cannot be made without more or less expense, and I do not see any adequate object to be gained by it under existing circumstances. However, it is within the province of this meeting to propose a resolution on the subject, and I shall be prepared to receive a resolution and submit it to the meeting.

Mr. Maturin asked if it was to be understood that the directors did not recommend the subdivision?

The Chairman said that the directors thought that it was not sufficiently important to justify them in advising the shareholders to make the change.

Mr. George Whitley moved that the regulations of the company be *not* altered.

Captain S. A. E. Barrow seconded the motion.

The Chairman put the motion to the meeting, and it was carried unanimously.

On the motion of Mr. Porter a vote of thanks to the chairman was passed by acclamation, and the proceedings terminated.

THE INDIA-RUBBER, GUTTA-PERCHA, AND TELEGRAPH WORKS (COMPANY) LIMITED.

THE half-yearly general meeting of the above company was held in the Cannon Street Hotel, on the 25th inst., Mr. George Henderson, chairman of the company, in the chair. The secretary, Mr. W. J. Tyler, having read the notice convening the meeting,

The Chairman said: Gentlemen, we do not, as you know, issue any report or statement of accounts for this meeting. I dare say you will be glad to have some information as to what we have been doing for the past six months. I am glad to say that in most departments of our business we have been fairly well employed, and can report an increase of sales, apart from cables, of about £33,000 over the first half of 1881. The market price of our staple material—india-rubber—has considerably advanced, and to meet this, as far as possible, we have raised our selling prices, though not sufficiently to cover the advance. We are doing a good business with our own Government in the departments of the Admiralty, War Office, and Post-office, and have obtained a share of the business arising out of the increased use of electricity. As to cable construction for the half-year, we have executed a second contract with the Mexican Telegraph Company, having manufactured and laid for them a cable of about 275 miles, as an extension of their system in the Gulf of Mexico. This gave employment to our steamer *International*, which after completing that work was engaged to repair one of the International Ocean Telegraph Company's cables between Florida and Cuba. Early in the year we supplied the West India and Panama Telegraph Company with 300 miles of cable, and in May the French Government with 140 miles for the coast of Tunis. The French Government continues to employ us both here and in France. At Persan we are making a considerable quantity of underground cable for it; and at Silvertown we have in hand a second Tunis cable of 260 miles, the laying of which in the autumn will give further employment to our steamer the *International*. The chief work of the year, the Central and South American Cable expedition, has proceeded very satisfactorily. The *Dacia* has returned, having accomplished her share of the work, and the *Silvertown*, according to the latest telegrams from our engineer, Mr. Robert Kaye Gray, is engaged in laying the last section. He expects to have the whole system completed from Vera Cruz to Callao, amounting to over 3,000 miles of cable, by the end of the present month. Happily the expedition has been conducted hitherto without important accident or serious illness, and all our staff have worked cheerfully and energetically in spite of long hours and much exposure in a trying climate. We hope to meet you again in February with a good account of the year. To-day you are called together chiefly to sanction the payment of the usual *ad interim* dividend of 5 per cent. Before concluding, however, I ought to mention that on the dissolution of this meeting an extraordinary general meeting will be held for the purpose of electing an auditor to act in conjunction with Mr. Weise, in the room of Mr. James Cowan, deceased. I have merely now to move that the *ad interim* dividend of 5 per cent., or 10s. per share, free of income-tax, payable on the 26th inst., be now declared.

Mr. S. W. Silver seconded the motion, which was put to the meeting and carried unanimously.

The Chairman said he was perfectly certain that their manager, Mr. Gray, and staff would do everything in their power to conduct the business satisfactorily.

The extraordinary general meeting was then held for the purpose of electing an auditor in the room of Mr. James Cowan, deceased. The secretary having read the convening notice, Mr. Hanson said that he would be very happy to propose for the vacant auditorship a gentleman who he thought would do good suit and service to the company if elected, though he was not offering himself as a candidate. He was a large shareholder, of very good commercial experience, and in early life was accountant in a Joint Stock Bank, so that he ought to know something of accounts. He is now a director of the National Bank of Australasia. He held 216 shares, and therefore had a considerable interest in the status of the company. He begged to move that Mr. Abraham Scott, of 4, Palace Road, Streatham Hill, be elected auditor for the current year in the room of Mr. Cowan, with a remuneration of 30 guineas.

Mr. Randall had great pleasure in seconding the nomination. He regretted very much the loss of the gentleman whose place Mr. Scott was nominated to take.

The Chairman put the motion to the meeting, and it was carried unanimously.

Mr. Scott briefly expressed his thanks for the honour they had done him in electing him to the vacant post; he only hoped he would be able to serve them as well as the gentleman whose loss they so greatly regretted.

Mr. Hanson said that before they separated they owed it as a duty to their directors, to offer them their best thanks for the success that had resulted from their management of the company's affairs. He thought the best proof they could have as to the stability of their position was that very little fluctuation in the value of their property ever took place; whether there was war in Egypt or anywhere else, their property remained very much the same. He begged to move a vote of thanks for the directors.

Mr. Treble seconded the motion, which was passed by acclamation.

The Chairman briefly responded, and the proceedings then terminated.

THE EUROPEAN, AMERICAN, CANADIAN, AND ASIATIC CABLE COMPANY.

THE prospectus of this company has been issued, and according to it we learn that it "proposes to establish international telegraphy upon a system of mutual profits, and to work at a much lower word-rate than the existing cable companies offer to the public.

"The Act authorises the establishment of telegraphic communication between Sable Island and any other point or points on the shores of the Dominion of Canada that the company may select, and such point or points on the coasts of Great Britain, Ireland, and the Continent of Europe or elsewhere, as the company may determine, and from any point or points on the Pacific coast of the Dominion of Canada to Japan and the Continent of Asia.

"The company has also power, with the consent of the Governor in Council, to connect the cables which are contemplated by the Act with the Government internal telegraphic system of the Dominion or with the lines of any telegraph company in Canada.

"The company starts with a threefold advantage. Firstly, it is free from the dead weight of unproductive capital which has been created in the case of other companies to the extent of some millions sterling, owing to several of their Atlantic cables having been abandoned, or rendered unserviceable; secondly, it has all the advantages of experience acquired in construction and laying by former companies; and, thirdly, instead of starting with over-costly and short-lived cables, it has entered into a contract with the well-known Henley's Telegraph Works Company, Limited, for laying down about 6,120 miles of cables, comprising two complete cables between England and Sable Island, and connections with Canada and the United States, at an agreed price of £1,443,176.

"This contract will place the company in a very favourable position as compared with existing cable companies, as is shown by the following facts:—

"The Anglo-American Telegraph Company, Limited, with a capital of £7,000,000, has three cables in working order, and it is said a fourth has been recovered and repaired; the Direct United States Cable Company, Limited, with a capital of £1,300,000, has only one cable; the French Atlantic Cable Company, with a capital of £1,700,000, has only one cable; thus showing five cables representing a capital of £10,000,000. It will further be noticed that this company will have two separate cables across the Atlantic, thereby rendering it independent of external aid, a feature of such self-evident importance that it is not necessary to dwell upon it any further.

"The life of such cables as it is proposed to lay may be safely taken at not less than 20 years, and provision for complete renewal at the end of that time should be ample.

"The company has therefore decided upon carrying on business at uniform low rates, instead of pursuing the vacillating policy hitherto in vogue of tentative reductions, with alternating augmentations.

"A tariff of 9d. per word between England and New York and Eastern Canada will be adopted, which, if necessary or advisable, can be reduced to even a lower figure. (The present rate of the combined companies is 2s. per word.)"

"Experience has shown that the existing companies are unable to work profitably at a tariff of 1s. per word. This company will, therefore, doubtless obtain as much of the traffic as its cables will be able to carry.

"It is computed that the entire working capacity of the proposed cables is equal to the transmission of about 14,000,000 paying words, during 300 full working days, but taking 10,000,000 words as a reasonable average, and allowing £80,000 for working and other expenses, according to careful estimates, the net returns would read as follows:—Gross revenue, 10,000,000 words at 9d., £375,000; less renewal fund, £45,000, and working expenses, £80,000, £125,000; leaving a net profit of £250,000, or equal to about 17 per cent. on the company's capital."

Since the prospectus appeared a letter has been addressed to the editors of the various newspapers by Mr. Weaver, of the Anglo-American Telegraph Company, and on the following day a reply was sent by Mr. S. Leith Tomkins, the secretary of the new company. They are very interesting, but as we hope to deal with the whole subject fully in an early issue, we do not intend publishing them, but shall refer to the leading parts of them when reviewing the subject in detail.

THE GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED.)

THE ninth ordinary general meeting of the above company was held on Thursday the 27th inst., in the City Terminus Hotel, Cannon Street, Mr. John Pender, M.P., chairman of the company, presiding.

The Secretary, Mr. William Payton, having read the notice convening the meeting, and also the minutes of last meeting, the latter were approved and signed.

The Chairman said: Gentlemen, I presume you will take the report as read (agreed). Before I make any remarks generally upon the present state of telegraphy, I will preface them by referring to a little of the detail which has been carrried on during the last twelve months. I want first to call attention to the fact that we have not been inactive during the past year, and have been enabled to make some tangible exchanges, which it is believed will be for the benefit of the company. The proprietors should remember that these exchanges are made mainly in the interests of the shareholders. The wider the basis of our operations, the more we can exchange on proper terms so as to extend the range of our securities, and the greater interest ordinary shareholders obtain. We have had a very large holding in the German Union Telegraph and Trust Company—£180,000, which company is the agent of the German Union Telegraph Company, Berlin. The company found it necessary, in the interest of the growing traffic and to avert competition, to lay a second cable from Embden to Valencia, so as to secure direct cable communication from the German Telegraph Union to Ireland without passing through the country, as formerly. You are aware that the French had a certain *esprit de corps*; and the Germans, of course, seem to have taken the same idea; and to meet the requirements of the growing traffic, they thought it better to have their own direct line from Germany. That cable has been made and laid, involving a duplication of the capital

of the Berlin company, and they issued 5½ per cent. preference shares. Your directors thought it well, having regard to the large holding of ordinary stock represented by the trust shares, to secure not only a rateable number of the 5½ per cent. shares. The directors felt it essential to cover the risk of the German Union by accepting these preference shares, which, no doubt, are of quite good security; for the German Union paid 10 per cent. for the year 1880, and 8¾ per cent. for the year 1881, and the prospects are now better than they have been. The purchase being large, involving something like £140,000, the available cash balance of this company and the trust certificates were applied to this purchase, and we also had to borrow £18,000, which is the extent of our liability in this purchase. We have been enabled to acquire preference shares at a price which will give 5½ or, say, 6 per cent. for our preference and 4½ for our ordinary shares. We have acquired also a parcel of German Union Telegraph cable shares, and have exchanged 500 Indo-European shares for our shares on favourable terms, and also 1,000 Eastern Telegraph shares. The Indo-European and the Eastern we look upon as a very valuable property. We declared, in the year '80 and '81, dividends on the ordinary shares of 4½ per cent., and your board regret to have to show a falling off from this rate of interest. It is a small falling off, but they hope they will very soon recover it. It is attributable to one cause only, that is, the competition in the Atlantic. In the financial year ending July, 1881, we received 3¼ per cent. from the Anglo-American Company, making the sum of £36,400; during the last financial year, ending July, 1882, we only received 2¾ per cent., or £30,800, a difference of £5,600. This is the main reason why the dividend is diminished. The two shilling tariff now in force is bringing in such an amount that I am hopeful that the next dividend of the Anglo-American will be such as to enable us to recover the dividend paid last year. In regard to the expenditure, there is very little difference as to the result of the year, and we give full details of our very modest outlays. When we made exchanges of shares in the ordinary course of business from time to time, we applied to the Committee of the Stock Exchange for an extension of the quotation, so as to embrace the number of shares issued and keep our quotation and issue in perfect order. The number of shareholders is still on the increase, and I presume we may take it as an evidence of the popularity of the security which the company offers, that while last year it reached the large number of 5,800, to-day the number of shareholders is 6,250. Since last I met you here our friend and colleague, the Right Hon. W. N. Massey, has passed away, and in him we have lost a man of very good sound sense. He was associated with the Globe Company from its very commencement, and his death is a loss which we all deeply regret. We have appointed in his place at the board Mr. Henry Daniel Gooch, son of Sir Daniel Gooch, whose name is honourably associated with submarine telegraphy. Mr. Gooch has also had some experience of a telegraph company, and therefore we have in him a younger life and a valuable accession to the board. Mr. Newmarsh, one of our auditors, has also passed away. His reputation was world-wide, and every one who saw his name was satisfied that the work he had to do was accompanied with the highest sense of honour. We have appointed in his place—or, rather, the shareholders at the last meeting were unanimous in appointing—Mr. William Griffith, B.A., Barrister-at-Law. So far as I have had an opportunity of observing, Mr. Griffith has been very careful indeed in seeing that the accounts of the company are in proper order. Now I have to make a few general remarks. In the first place I may refer to the Anglo-American competition in the Atlantic. I daresay you have read in the newspapers the prospectus of the company which was launched last Saturday, and seen the report of the managing director—or rather the criticism of the managing director—of the Anglo Company. That is so complete that I need scarcely add one word. The only thing I may say is that it does astonish me in a great commercial city that such a prospectus should have been seen. It is such that the men who have prepared it, and I am afraid, many of the honourable names associated with it, had not in the slightest degree a knowledge of what it implies. I can only say this, that if the company is floated—which I have considerable doubts about indeed—it would be literally impossible for them to realise what they put forward in their prospectus. A grave responsibility, therefore, rests upon those who have issued this prospectus, a responsibility so great, that I am perfectly satisfied that when many of the names associated with it begin to realise their responsibility, the result will be that there is very little chance of its proceeding beyond the paper in which the proposal has been made. However, that is a thought resting entirely with those gentlemen. Just one point I may mention, as showing how extraordinary the statements are. They assume that notwithstanding the eight cables which we have now in the Atlantic, these eight cables being capable, when in good working order, of doing the work of sixteen cables, this new company assumes in their prospectus and in their calculations that they will do not only all the traffic that the other companies do, but something more than all the traffic that is obtained in the Atlantic at the present I think you will see at a glance that the old companies must be in a very extraordinary state if they stand still and see their business passing away. But as to the cable that they intend to put down, it would be simply impossible for them to do their work. They assume that they will do twenty-five words a minute. Sir James Anderson, who has had great experience of what the best manipulators can do, will tell you that sixteen words a minute is uncommonly good work. Therefore the whole statement throughout is one that, I am sorry to say, shows the greatest ignorance on the part of those who concocted it—and I think it is using a mild phrase to call it ignorance. Probably they would not be able to work their system at more than ten words a minute. Therefore, so far as I can say, and looking carefully into the figures, the chances are, that instead of showing a profit, a loss to such a company would accrue of nearly £50,000. There is another cable which is projected by Mr. Garrett, of the Baltimore and Ohio Company. I am making these remarks, for, as you know, you obtain good dividend from the existing companies, and these might be affected by such new enterprises. His scheme is to utilise, as far as possible, the telegraphs along a very extended and very important system of railway in America—the Baltimore and Ohio Railway. The Baltimore and Ohio Company have not themselves obtained an Act of Parliament at Washington for new lines, but the members connected with the system have obtained this act. My own impression is that the men connected with this company are shrewd men, not likely to get any money in America, if they can get it in England, and are quite justified in getting this addition to their system. But my own impression is that while our telegraph lines generally are at 50 per cent. discount that is not likely to be realised. I think there is a probability that even Mr. Garrett, shrewd man as he is, will reconsider the question before he even induces his friends to go into this large expenditure. I think that now, with a working power which is represented by something like 16 cables in the Atlantic with the duplex system, I think it is possible to provide Mr. Garrett's system with as much cable power as he requires for operations in America, and, therefore, as I have always been a man of peace with regard to submarine telegraphy, I have always thought it better that there should be combination rather than fighting with one another, because in the long run compromises have to be made. I am hopeful that before I have the pleasure of seeing you again we shall have some means whereby we can utilise Mr. Garrett's system by gradually improving our own. The next system that I must refer to is that of the Eastern system of telegraphy and its Eastern Extension. I daresay you are all aware of what is going on in Egypt at the present moment, and probably no company is more prominently before the public engaged in doing good and useful work for the community at large than that company. Had it not been for the arrangements made by the Eastern Telegraph Company we should have been, I believe, without any communication with Egypt to-day. I am sorry to say we have not to thank the Government very much for providing us with anything. We have provided the Government with means for securing a rapid, and perhaps the best, working system of telegraphy between Egypt and Europe at the present. That has been done entirely by forethought, by bringing a ship, at very considerable expense, from the Red Sea to Alexandria, establishing on board that ship our working system, so as to keep the public informed as to all that is going on in these waters; so that every hour in the day when the newspapers bring out a fresh edition, that fresh edition springs entirely from the telegraphic communication established by the Eastern Company. We have at the moment an interruption to our system in crossing the Isthmus of Suez. I am sorry that interruption should exist. If we had had our own way it would never have existed, and I hope that we shall be, before very long, able to show the Government that the Indian Empire is of some consequence to England, and that England should not be backward in retaining good telegraphic communication, which is so valuable at the present. I say this without fear of contradiction: if the system of telegraphy was suspended for one week between England and India I dread what the consequences would be. If it were suspended at the present, any dilatoriness or delay of our Government in giving the instructions would have serious results. There is another system working to India, that is the Indo-European system. That is a valuable system in its way. We, I may tell you, are partners in that system, and therefore at the present moment we are not losers to any serious extent by the interruption of our system; but I think it is desirable that England and India should not be entirely dependent upon this one line, which passes at the present moment through Germany, Russia, Persia, and the Persian Gulf. Only yesterday one cable in the Persian Gulf was interrupted, another might be to-morrow, consequently an alternative line is desirable. That, we have in full working order; but we are working in perfect harmony with that system, forming an arm of the general system, and for the present moment of a system still forming a connection, but an uncertain one, between England and Persia. I am hopeful that before long we shall be able to communicate again with India by the Suez Canal. We, of the Globe Company, as advisers to the other companies, and as being interested in these other companies, made it our special business to see Government almost daily on the subject, and we urged on them the importance of having this communication re-established with India and Europe. With these remarks I beg to move that the report and accounts of the directors submitted to the meeting be, and hereby are, received and adopted, and the following dividends be declared payable this day, 3s. on the preference shares, being 6 per cent. for the year ending 18th July, 1882, and 2s. 9d. on the ordinary shares, making 4½ per cent. for the year ending the same date, both free from income-tax.

The Marquis of Tweeddale seconded the motion, which was carried unanimously.

The Chairman: The next resolution is that the Marquis of Tweeddale be, and hereby is, re-elected a director of this company.

The motion was seconded by Sir James Anderson, and carried unanimously.

The Chairman: I have also to move that Mr. Henry Daniel Gooch be and hereby is re-elected a director of this company.

Mr. W. Ford seconded the motion, which was likewise unanimously carried.

The Marquis of Tweeddale and Mr. Gooch having briefly thanked the shareholders for their re-appointment, Dr. W. F. Gredge moved that J. G. Griffiths, Esq., F.C.A., and W. Griffith, Esq., B.A., be re-elected auditors of the company, at a remuneration of thirty guineas.

Mr. Scott seconded the motion, which was put to the meeting by the Chairman, and carried unanimously.

Mr. Griffiths briefly expressed his thanks to the meeting.

A vote of thanks to the chairman was then moved by Mr. Gardner, seconded by Mr. Benson, and carried by acclamation.

Mr. Pender responded.

The proceedings then terminated.

THE TELEGRAPHIC JOURNAL AND

Electrical Review.

Vol. XI.—No. 245.

FIRE RISKS FROM ELECTRIC LIGHTING.

We are glad to observe that the rules and regulations relating to the above subject, which were drawn up by the committee of eighteen eminent men of science, appointed by the Society of Telegraph Engineers and of Electricians, have been severely criticised by the correspondents of some of our contemporaries. At the time these rules were published in our columns we took the opportunity of expressing our opinions on their value to electric light engineers, and we see no reason to alter the course we then took. In our review we stated that in no part of the Committee's report was there any suggestion thrown out as to any simple or convenient means of following up the skeleton ideas therein contained. We could not at the time devote sufficient space to the matter for dwelling upon many of the points deserving of attention, but as the subject is one of considerable importance, it may be well to return to it. Speaking of the construction of a dynamo-electric machine, the Committee says:—"The insulation of its coils and conductors should be perfect." Doubtless every manufacturer of dynamo-electric machines does his utmost to attain this impossible object, and it is more than probable that they all have different methods wherewith to get the nearest approximation to the desired insulation. It would have been an easy matter for the Committee, or certain members of the Committee, to have instituted a series of experiments as to the simplest, most efficient, and most durable manner of insulating the coils on the armature or electro-magnets of such machines. It has been done by means of dipping the sections of cotton-covered copper wire in melted bitumen or paraffin wax, and in shellac varnish, but there are certain objections to all three. The coils of the French made Gramme machines, we believe, are generally steeped in bitumen, and we feel convinced that this is calculated to retain the heat developed in the bobbin when the machine is at work. When paraffin wax is employed, it melts when the sections of the armature attain a moderate temperature, and it then flies off like oil. Shellac varnish makes the cotton too hard and brittle. It was within the province of the Society of Telegraph Engineers' Committee to study these points, or to seek the necessary information from those practically engaged in constructing dynamo-electric machines. It would then have been an easy matter to decide as to which was the most desirable method to adopt for insulating section from section. The insulation of the commutator or collector slabs is also a nice point. In regard to the conducting wires there is absolutely nothing said beyond the well-known fact that they should be efficiently insulated.

How is this to be performed is the question. As we have before explained, an insulation which may appear perfectly good whenever the current used does not exceed 100 volts electromotive force, may be completely broken down when a higher tension is employed. It is absolutely necessary that for a permanency we must use something more substantial than a wire covered with several layers of tarred yarn or tape, and we must therefore fall back at present upon gutta-percha or india-rubber. It is well-known that the former preserves its insulating capacities for almost an indefinite period when under water, but if exposed to changes of wet and dry, or to a moderate heat, it soon becomes useless. India-rubber possesses considerable advantages in these respects over the former, but it is a more treacherous material to use, and a fault in it is much more difficult to find than in gutta-percha, owing to the elastic nature of the material, which partially closes up again if severed. Why did not the Committe appointed to consider these matters explain to those wanting the information the best methods of insulating wires for use under various conditions? The Society's Committee apparently makes a great point of safety plugs. We have never yet been able to understand why a fusible plug in the main circuit, which would be melted if the current attain any undue magnitude, and thus break the circuit, should be called the *very essence of safety*. There are risks inherent to this means of illumination other than that of fire, as the Committee expressly call attention to at the conclusion of the report. Why cannot such a device be abolished altogether, and an electrical safety valve—if we may use the term—be employed to divert part of the current into another channel when it becomes too great for the purposes required? Even supposing a current does attain undue magnitude, it could scarcely be a desirable thing to happen, that a mill, factory, coal mine, or private mansion, should be suddenly enveloped in darkness because a fusible plug had melted. One would hardly expect an extensive manufacturer, or user of steam boilers, to make a weak place in his steam pipes, so that they might burst if the steam exceeded a certain pressure on the square inch, even supposing they were carefully boxed up and no damage done beyond stopping the machinery. We have always advocated the frequent testing of every part of an electric light installation but we cannot agree with the Committee, that electrical testing is an operation, *skill in which is easily acquired and applied.* Men may be taught in a short time the use of recently devised instruments of a simple and portable character, but the operation would be of a purely mechanical or imitative nature, and without in the least understanding the principles involved in such tests.

The two meagre sentences devoted to lamps give us no information whatever. It is, however, suggested that "the lanterns and all parts which are to be handled should be insulated from the circuit." As the lamps constitute those parts of the circuit from which it is most likely that shocks would be experienced, we think that some hints might have been given how to practically carry out the Committee's suggestion. We have on several occasions known of accidents from this source, and in two instances a man was knocked backwards from a ladder he had mounted for the purpose of regulating a faulty lamp. We believe that mishaps of this kind, which might have turned into serious accidents, are of frequent occurrence.

There are two rules relating to "Danger to person."

We are told that it is essential that "there should never

be a difference of potential of more than 200 volts between any two points in the same room." As this regulation is to secure persons from danger inside *buildings*, we should like to know how in a large shop, illuminated, say, by means of six or eight arc lamps, the two points can be avoided where the difference of potential does not exceed 200 volts. Of course, the wires entering the room might be so far apart that it would be impossible to receive a shock from two such points, but the Committee does not mention how such a contingency is to be avoided.

The rules and regulations as they stand might form the basis or outline of an exhaustive treatise on the subject, and perhaps the Council of the Society of Telegraph Engineers and of Electricians may reconsider the subject and re-issue a pamphlet which shall recommend itself to all as an authority on this most important matter. As it stands it forms more a subject for ridicule than for serious consideration.

EXPERIMENTS WITH UNDERGROUND TELEPHONE LINES.

[In Vol. IX. of the ELECTRICAL REVIEW, and on pages 5, 148, 149, 297, 306, 316, and 338, we described fully the method of insulation for underground conductors adopted by Mr. David Brooks, and the various tests which his process had been submitted to from time to time. We believe that the officials of the British Postal Telegraph Department entertain favourable opinions on its merits. It has not yet, however, had time to fully prove its capabilities, but as far as the trials have gone on thirty wires between Waterloo and Clapham the results have been quite satisfactory. We extract from an American contemporary, the *Operator*, an article giving some details of practical telephonic experiments which have recently taken place in America, and which will be perused with interest.]

"A SERIES of tests of a subterranean telephone line was undertaken on the afternoon of July 12th in the little booth of the Western Union Telegraph Company on the dock at Communipaw, N. J. We find the following report in the New York *Times*:—

"'It is now four years since, in Philadelphia, a mile of subterranean cable was laid from a point near the old Pennsylvania Railroad depôt in the direction of Gray's dock on the river. The experiment was made under a patent obtained by Mr. David Brooks, of Philadelphia, who had just invented a new mode of insulation for telegraph or telephone wires, the main specification of which consists in the use of a fluid hydrocarbon or gas. As laid down between Newark and Jersey City, the Brooks system is very simple. The length of the pipe in which the wires are enclosed is nine and a half miles. The pipe may be of any convenient diameter, and is smoothed internally by means of a sand bath. The wires (No. 16 copper) are wound with cotton or jute and pulled through the pipe by means of a powerful capstan. The length that may be pulled through at any one time, and the largest distance between the joints, consequently, is about 3,000 feet, or a little more than half a mile. When the wires have been pulled through the pipe and the latter has been laid in place, the remaining space (not occupied by the conductors) is filled with paraffine oil, which operates as an insulator, excludes all moisture, and perfectly performs its office. On the top of Bergen Hill is a tank which contains seven barrels of oil and communicates with the pipe containing the telephone wires. The pipe from Newark to Jersey City possesses a capacity of about ten barrels. There is thus the constant pressure of the seven barrels of fifty gallons each on the pipe in which the wires are enclosed, and thus any alteration in volume occasioned by the expansion of the oil at summer heat and its contraction in winter is compensated for, and no water can possibly enter the receptacle. It costs about 10 dols. per wire per mile for a tube containing 100 wires to lay such a cable, whereas it costs no less than 50 dols. per mile to put up telegraph wires in the ordinary way.

"'The success of the experiment in Philadelphia in 1878 led to the sale of the patent to the Western Union Company for telegraph purposes at a price of 190,000 dollars, and the inventor went to Europe immediately after to introduce it there. Sections were laid in Belgium, France, and England, and were eminently successful.

"'In the meantime an attempt was made to lay a cable from Newark to Jersey City by the Western Union Company, and some five miles of wires were put down in the salt meadows, but the Jersey City and Newark authorities refused permission to disturb the streets, and the project had to be temporarily abandoned. When Mr. Brooks returned from Europe he hit upon the idea of availing himself of the right of way of the railway between Newark and Jersey City. He thus obtained access to both, and connected the Western Union offices in Newark with the station on the dock at Communipaw. The cable is not laid in the best manner, but the experiments were no less successful than if the inventor had superintended every rod of the work. The material used for insulation is the second distillation of petroleum, or rather the residue that is left—a thick, heavy oil, good for lubricating purposes—after the burning fluid has been distilled off. This residue contains traces of soda and sulphuric acid, which would corrode the wires if left in the oil; and this fact renders a second distillation necessary, which slightly increases the cost per gallon. In the experiments yesterday afternoon the two points it was proposed to determine were the amount of interference by induction and the general practicability of the system. It is a familiar fact to the reader that when he puts his ear to the loud receiver of the telephone to listen to a person at the other end, voices not intended for his benefit, and really passing on other wires, are passed over to the conductor that he is using. This faint electrical reverberation is styled induction, and how to get rid of it has been one of the problems of telephone engineering. There is also a frying sound that is due to induction, and there are other difficulties that are familiar only to experts. Combined together, these difficulties have hitherto materially interfered with transmission at long distances, and it was claimed that they could not be overcome if subterranean wires were used.

"'The experiments yesterday were witnessed by a few persons only, among whom were Mr. Vail and Mr. Jaques, manager and electrician of the Bell Telephone Company, of Boston; Mr. J. W. Dyer, a Philadelphian electrician of high repute; Mr. Chinnock, electrician of the Metropolitan Company of this city, and Mr. Davis, its president; Mr. Robinson, of Philadelphia; Mr. Brooks, the inventor, who took no material part in the tests, and a few other gentlemen. In order that experts of the best skill might be at both ends of the cable, Mr. Chinnock went to Newark and operated the Newark end, while Mr. Dyer and Mr. Jaques operated the instruments at Communipaw. The wires had been connected until a circuit of 150 miles in length was established, and this was first tested.

"'There were some embarrassing circumstances, one of them being the fact that the Western Union system, using a dynamo equal to 185 volts at this end and a 60-cell Calland battery at the other, was in constant operation, parallel with the telephone wires. The first test was made with grounded wires, Mr. Dyer talking with the operative at the Newark end while Mr. Jaques listened for induction interference. The voice of Mr. Chinnock could be faintly heard as a result of induction, but Mr. Jaques pronounced it not sufficient to interfere with the practical working of lines. One wire after another was thus tested, with substantially the same result, both with the wires grounded and not grounded, in order to measure the induction as a separate factor. The next experiment was to connect several series of wires into metallic circuits, and to institute the same series of tests as to induction. No. 1 and No. 2 were first employed in this manner, and there was absolutely no sound brought to the ear by the second receiver. When No. 9 and No. 10 were similarly connected and the tests were applied the voice at the other end was heard in a faint, far-off manner, and only an occasional word could be distinguished. The same was the case with a circuit composed of No. 23 and No. 24. The experiments occupied the whole afternoon.'"

DIVISION AND SUBDIVISION OF THE ELECTRIC CURRENT.

IN our "Notes" will be found a letter from the pen of Mr. John Banting Rogers, who claims to be the inventor of the *division* and *subdivision* of the electric current. As long as Mr. Rogers was privately engaged with his work we refrained from setting aside any portion of our columns, to show the evident want of the merest elementary knowledge of electrical matters displayed in the fantastic creations of his brain. The subject has recently, however, assumed a public form, a J. B. Rogers Company having been promoted and the name of a well-known expert, who had reported on the system, dragged into the controversy now going on in the daily press in a manner not particularly creditable to either party; and we therefore feel compelled to comment on this subject in such a way as to bring it to a close once and for all, if possible, as far as we are concerned. We cannot, however, be so severe upon the originator of these so-called inventions as upon those who have so strenuously encouraged him in his erroneous ideas. Certain of our contemporaries have probably done more to keep the name of Mr. Rogers before the public than even a portion of the daily press; and these should really be held responsible for any injury which either Mr. Rogers, or those associated with him, may have sustained. We will, in the first place, allude to the claim set up by Mr. Rogers and others on his behalf, as to his being the first inventor of the division and subdivision of the electric current. We have before remarked, when speaking of the Company promoted for working the J. B. Rogers inventions, that a claim for the division and subdivision of the electric current could not be sustained, as in all electrical work the current may be made to flow in one or many directions, as the circumstances require. We will, however, bring before the notice of Mr. Rogers one particular patent (Werdermann. Apparatus for Electric lighting, dated 21st June, 1878) in order that he may know what had been done in incandescent or semi-incandescent lighting prior to the 20th September, 1880, the date of his first electrical invention.

The third claim of Mr. Werdermann reads as follows :—

"The apparatus or arrangements comprising the series of parallel circuits in connection with my improved lamps or other suitable lighting devices with or without artificial or special resistances, in the manner illustrated and described in connection with figs. 13 and 14 of the drawings, whereby I am enabled to effect the division of the electric current to produce any desired number of lights in connection with one battery, or other source of electricity, in such a manner that each one of such lights may be regulated, or extinguished, without affecting any, or either, of the other lights," &c., &c.

Leaving this for the moment we will return to the specification of J. B. Rogers, which is set forth in the following words :—

"The object of this invention is improved means and apparatus for dividing and subdividing the electric current for lighting or other purposes, by means of pairs of spherical, conical, hemi-spherical, bell, or flat, square, or other suitable shaped metallic bodies, to one portion of which are clips or other appliances for the attachment of the primary wires from a dynamo machine or other electric force producer, and with a series of other clips or appliances on the bands,

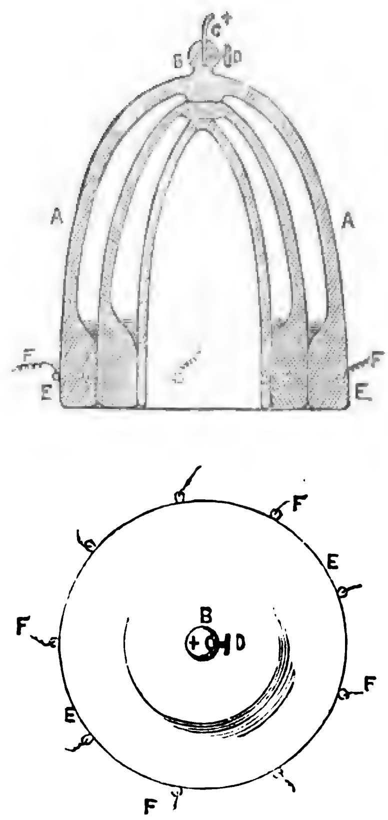

FIG. 1.

bases, or edges of the metallic bodies, to which other wires can be connected for conducting the fluid to any desired number of lamps or carbons, or to other shaped vessels or metallic bodies arranged in pairs, from which again wires can be conducted to other lamps or carbons. The apex of the bell or other shaped vessels or cups, if of bell shape, is preferably of greater thickness than the body for *accumulating and governing the fluid* (the italics are ours). The bands are also of greater thickness than the body for a similar purpose.

"Should the vessel have a spherical or globular form, the clips above referred to may be fixed upon a central band or belt; and instead of the single clips being on the apex it may be fixed to the collar or stem on which the globe stands.

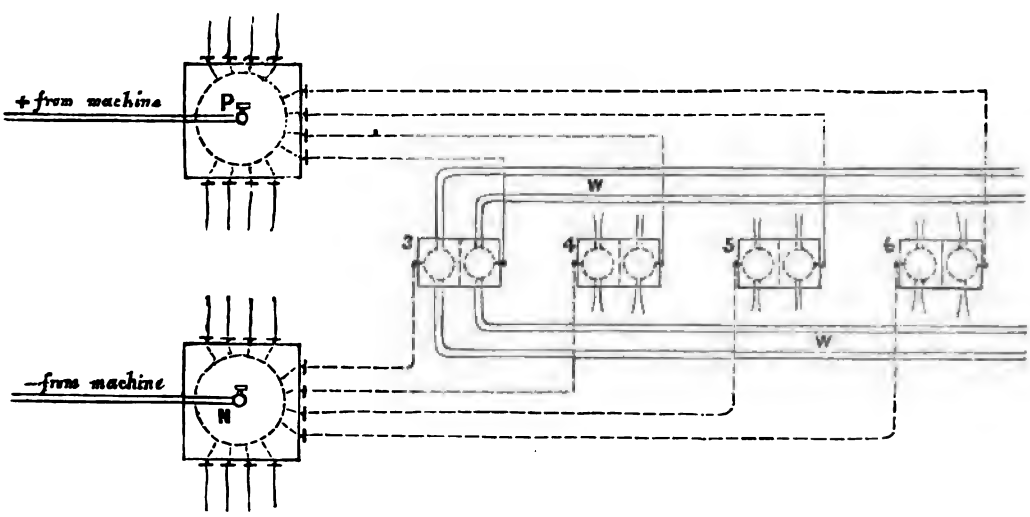

FIG. 2.

"For intensifying light, the series of clips on the bands of the vessels may have the primary wires of electric force producers, or of several of them, attached to them so that the united fluids may be transmitted through the apex wire of the bell-shaped vessel, or through the collar wire of the spherical vessel to one or more lamps or carbons.

"Any number of my metallic bodies may be used between the force producer and the light or lights if desired, for intensifying on the one hand, or dividing on the other."

The specification sets forth in the usual manner that the invention will be clearly understood by the accompanying drawings, and as we consider fig. 1 the most comical of any we reproduce it in plan and section.

We extract from the specification the explanation of these devices :—

"Fig. 1 is a section and plan of a bell-shaped apparatus, A, with lining vessels in the interior for current intensifying and distributing purposes ; B is the apex, with a conducting wire, C, attached by the screw clip, D, and E is the band or base around which a series of other conducting wires, F, are looped, or they may be attached in any other convenient manner, said wires, F, F, leading to and connected with electric lamps for producing light from one main dynamic or other force producer, as before mentioned, or for distribution of current for other purposes."

It is specially stated with reference to the drawings that "the above described figures only indicate a few of the devices which I intend to adopt for the purposes of my invention—viz., an apparatus for gathering or accumulating the electric force or fluid given off, or from, a dynamo-electric or other current producer, and by, in, or through said apparatus, so dividing or subdividing the current that several lamps or lighting appliances or apparatus in or by which the electric light can be established is effected, or its distribution for other purposes."

The specification is adorned with a second sheet of drawings, mainly consisting of a diagram showing these marvellous boxes connected up for use. We extract a portion of the sketch, which we prefer to have explained in the inventor's words :—

"Fig. 2 is a diagram of my system of subdividing and distributing the current ; P, N, are a pair of primary apparatus with twelve subsidiary wires each, positive from one and negative from the other. Each pair of branch wires from the primary apparatus is led and attached by any of the usual connection appliances to smaller apparatus, 3, 4, 5, 6, in which the current is gathered or accumulated, and passes by the subsidiary wires, W, W, of these smaller apparatus to other but still smaller apparatus from which are other subsidiary wires to lead the current for its intended use, or to other and smaller apparatus for a further distribution of the same, this system being carried on to any desired extent."

The inventor claims—

"1st. The system or means for gathering or collecting electric current into intermediate vehicles arranged in pairs, and in distributing said current therefrom by subsidiary conducting wires, as described, especially for lighting purposes, as set forth.

"2nd. The several apparatus shown on sheet 1 of the annexed drawings, and their employment in pairs as vehicles for the division and subdivision of the electric current, substantially as on sheet 2 of the annexed drawings, for the purpose or purposes set forth."

So much for this so-called patent which has had the support of two or three leading daily papers, and several of our scientific contemporaries, amongst them one dealing exclusively with electric lighting matters. Perhaps they might, if according any further notice to the matter, explain the difference between the circuit connections of Mr. Rogers and those adopted by Edison, Swan, and others. There is certainly a difference, in so far that in the one case the wires constituting the mains, submains, &c., are properly connected to each other where required, and in the other an extra piece of metal is put in circuit to increase the chances of bad joints or disconnections.

We must ask the pardon of our scientific readers for bringing forward the "*multiple terminal*" arrangement of Mr. J. Banting Rogers, and when we state our reasons for so doing we feel sure of their tolerance. The present year has been unprecedented in the introduction of the subject of electric lighting amongst all classes, and we are well aware that journals in which reliable information can be obtained relating to the various systems brought forward are now extensively perused by the general reader or public ; and it is therefore in the interests of the latter that we have lent our columns to the consideration of that which would long since have sunk into oblivion had it not been for the causes we have already alluded to. Mr. Rogers may believe, and probably does, that he is the victim of prejudice, but in this he is entirely mistaken. Years before 1880 everything that appears in his specification was known and in use for innumerable purposes connected with electrical science. Mr. Rogers invites the public to come and see how far he has succeeded in lighting by electricity the cottage or the mansion, and in this invitation he is perfectly safe ; for if the public were competent to judge these things, Mr. Rogers and his system of division and subdivision would have been vetoed long since. If Mr. Rogers lives long enough he will perhaps eventually come to the conclusion that the opinion of scientists and demonstrated facts are very much alike, when the laws governing any branch of science are as well known as those of electricity. We trust that this matter will now gradually be forgotten, and should Mr. Rogers in the future devise anything relating to electrical science worthy of favourable mention, we shall be amongst the first to welcome it.

Doubtless he has worked energetically for a long period in the belief that he had achieved some decided step in advance of the present methods of utilising the electric current for the purposes of illuminating our streets and houses. It would have been well had the ridicule which he well knew his work provoked in certain quarters led him to reflect for a moment that he might possibly be making an error ; and then, had he been sufficiently wise to consult some electrician of known reputation, he might have been saved much trouble and annoyance, and we should have been spared the mental energy wasted in perusing his patent.

OBITUARY.

ANTOINE BREGUET.

We reserved our notice of the death of this gifted young scientist until we were able to place more information before our readers than has been possible hitherto. We are indebted to our French contemporary, the *Revue Scientifique*, for the long article we publish. We have it on good authority, however, that this Journal, with which M. Breguet was for long associated, credits him with more than he actually achieved, notably in the statements relating to perfecting the Gramme machines and the telephone of Bell. Be this as it may, electrical science has lost in Antoine Breguet one who could ill be spared.

He was descended from a Protestant family, who at the time of the Revocation of the Edict of Nantes sacrificed their interests to their religious opinions and took refuge in Switzerland. His great-grandfather, Abraham Breguet, came back to France at the time of the Revolution and established himself at Paris as a clockmaker. His important discoveries placed his reputation on a firm footing, and he was made a member of the Academy of Sciences. His grandfather, Antoine Breguet, also distinguished himself in his art. His father, M. Louis Breguet, the well known scientist, the inventor of a telegraph which has been in use thirty years, is at present a member of the Institut. It has been his sad lot to survive his son, on whom he looked as the hope and support of an honoured name.

Antoine Breguet was born at Paris, January 26, 1851. He pursued a brilliant course of studies at the Lycées Saint Louis and Bonaparte ; but a violent attack of rheumatism overtook him in 1870, at the age of 19, and seriously affected his health, leaving behind the germs of heart disease. This malady, as Antoine Breguet well knew, demands a life of calmness and tranquility, free from cares and fatigue. But he had a very keen sense of the responsibility imposed by an illustrious name, and also a laudable ambition to add to the fame bequeathed to him by three generations. Led on by this idea, and sustained besides by his high moral energy,

he gave himself up assiduously to work, without either relaxation or rest. He had a motto, which we have often heard repeated in joke: *Noblesse oblige;* and this is the explanation and the history of his life.

Scarcely recovered from his illness, he enlisted at the time of the war, although at his age he was not called upon to do so, and took part in the defence of Paris as lieutenant of the auxiliary corps.

After the war he resumed his duties and prepared himself for the Ecole Polytechnique, where he was received in 1872. On leaving the Ecole in 1874 he refused the public offices to which his rank gave him a right, and entered, as sub-manager, the factories built by his father for the construction of instruments for exact measurements and electrical apparatus.

At that time new and important applications of electricity were springing up on every side. The Gramme machine, the improved telegraphs, and the telephone, made their appearance successively. Antoine Breguet was one of the most ardent promoters of the new discoveries. He was one of the first to understand what an immense future electricity had before it, and he devoted himself to the study of this science in particular, without neglecting the administration and general direction of his firm. He himself directed, in his factories, the first attempts at constructing the new models presented by inventors; and thus on several occasions, important improvements suggested themselves to him.

Although the management of the factories was a difficult and absorbing task, Antoine Breguet contrived to devote a great part of his time to purely scientific studies. He attended the lectures of M. Mascart, at the College of France, and by reading the original papers he completely mastered the new theories, then little known, of the great English electricians, Faraday, Clerk-Maxwell, and Sir William Thomson. For Faraday, in particular, he expressed the greatest admiration, and to that illustrious physicist, whose profound researches into the nature of electrical phenomena impressed him deeply, he traced all the progress made in electricity during the last fifty years.

But soon, by his own personal efforts, he became known to the public as an inventor and *savant* of great merit.

We may mention an ingenious anemometer, invented by him in 1875 and moved by electricity, which registers, at a distance, and continuously, the speed of the wind. One of these instruments is at work at the Jardin d'Acclimatation.

In February, 1878, he addressed a note to the Académie des Sciences on the "Telephone and the String Telephones."

He had discovered the curious fact that every point of the telephone (magnetised bar, handle, &c.), or of a substance connected with it, vibrates at the same time as the plate of soft iron, and may serve to transmit sounds.

He verified this most elegantly by means of a simple toy called the string telephone. If, in fact, the extremity of a string telephone is fixed to any point whatever of the Bell apparatus, the sound is plainly heard at the other extremity. From this he showed a means of communicating to several persons at once, the sounds arriving at one single telephone. All that is required is a few string telephones connected to any points whatever of the Bell apparatus. The string of the telephone may, besides, by certain special arrangements indicated in the note, pass through comparatively great distances.

The same year he invented a telephone called a mercury telephone, which is essentially different from all those known before, and seems still more surprising than Bell's. The complete description of it is to be found in the *Comptes Rendus* of the Académie des Sciences (March, 1878). The receiver and transmitter of this telephone are identical, and consist of two very simple Lippmann electrometers, furnished with a membrane at the upper part of the tube. The vibrations of the membrane of the transmitter are communicated to the mercury or to the glass and produce variations of current, which the wire of the line transmits to the other station. The electrometer being reversible, the membrane of the receiver undergoes exactly the displacements of the transmitter.

This telephone does not necessitate the employment of a battery, like the Bell telephone. It offers the following advantages over the latter:—

It transmits any vibrations whatever.

It is independent of the resistance of the line.

This last property allows of substituting for the thick wires of the ordinary lines fine steel wires of small diameter, thus effecting a considerable saving of expense. He thought that this discovery would be turned to account in the ordinary telegraph, and that electro-capillary phenomena would be utilised for the transmission of force to a distance. He had the intention of making researches into this question; but, alas! he had no time. Shortly after he published in the *Annales de Physique et de Chimie* a very important article entitled "Researches into the Theory of the Gramme Machine, the Cause of the Unsymmetrical Position of the Brushes, and an incidental Study of Magnetic Screens." The outline of this article was presented to the Academy, November 11th, 1878.

The Gramme machine, which has been known for several years and is familiar to the *savants* of every country, still presented certain difficulties. To Antoine Breguet must be conceded the merit of being the first to give an exact and complete theory on the subject.

In this article he dwells first on the reversibility of the machine, and shows simply that it is derived from well-known instruments—the revolving disc of Faraday and Barlow's wheel. But these latter furnish a very weak current, and inventors have tried, by the addition of an inner ring of soft iron, or by a special method of coiling the wire, to realise, with small volume, a machine of great power. He examines the methods given by Frölich and Alteneck; and indicates a new and far preferable mode of coiling. He then shows the exact function of the ring in the different machines. It is useful in all, for it heightens the intensity of the magnetic field; but in the Gramme machine it is indispensable, and acts as a magnetic screen to protect the inner spirals of the coils.

He then analyses the causes of the unsymmetrical position given to the brushes. This anomaly had always been attributed to the retardation of the *demagnetisation of the ring of soft iron.* But the coercive force of the ring is, really, the least important cause. He shows, in fact—and this is the most original part of his discovery—that the deviation is chiefly due to the reactions which take place between the magnetic fields of the exciting magnets and of the current of the coils. He then gives, from the results of his experiments, the simple rules which enable one to determine, in every case, the most advantageous position to give to the brushes.

In this long paper he turns to the greatest account Faraday's lines of force, of which he had made a special study. He calls attention at the commencement to their principal properties, and in the course of the paper he states two new laws, which may be added to the two laid down by Faraday. They deserve to be quoted verbatim: *The density of the lines of force at a certain point is proportionate to the greatness of the force at that point. A line of force contained in a magnetic substance is magnetically shorter than that contained in a diamagnetic substance, or more generally in a substance less magnetic than the first.*

In a conference held at the Sorbonne in 1880 he gave the result of his researches on the lines of force, and showed the wonderful benefit to be derived from them. By their means he showed from the commencement the close analogies between electricity and magnetism, and easily recognised their principal properties. He explained simply the magnetic screens, the attraction of the soft iron, and the orientation of the diamagnetic substances. Besides, this theory of the lines of force enabled him to state that the metallic rings in motion cease to be magnetic screens, and the subsequent experiments of M. Lippmann confirmed this assertion. Thus he thought that the study of the lines of force, on account of its simplicity and its utility, would one day form a part of the rudimentary instruction in electricity.

From 1875 to 1880 he published several articles on fresh discoveries in different journals and reviews (*Bulletin de l'Association scientifique, Revue des Deux Mondes, Annales de Chimie et de Physique*). He held several excellent conferences on the same subjects at the Scientific Association of France, at the Sorbonne, at M. Würtz's laboratory, at the Ecole de Médicine.

In 1880 he undertook the editing of the *Revue Scientifique*, in conjunction with M. Charles Richet. He contributed an important share of the articles of every kind published

in this journal. He inserted in the *Revue* the first article published in a French journal on Graham Bell's remarkable discovery of the photophone. When the famous Bell arrived in France, A. Breguet installed in his factories the series of photophonic instruments, and invited various scientific men to witness the very interesting experiments of demonstration. Graham Bell, who was able to judge of Breguet by this circumstance, entertained the greatest friendship for him.

In 1881, A. Breguet was made the head of the service of installations of the electrical exhibition. Quite a young man, he had for five years been the manager of a great firm, and he had acquired the experience of middle age; he was well acquainted with all the scientific and industrial questions relating to electricity; he possessed besides a quality rarely found in a scientific man—the great art of judging men, and the habit of quickly seizing the main points of a question as well as its details. Add to this his invaluable natural qualities, his coolness, his unflagging gaiety and high spirits, and his marvellous tact. During the whole course of the electrical exhibition he rendered the greatest services to this truly national enterprise. He first conceived the happy idea of establishing telephonic communication between the Palais de l'Industrie and the theatres.

His work was not, however, limited to directing the installation of the exhibits. His scientific knowledge caused him to be called upon to take part in the important meetings of electricians held during the exhibition. He was also delegated by the administration to the International Congress of Electricians. At the end of the Exhibition he obtained the Cross of the Legion of Honour.

During this exhibition he had been convinced more than any one that the applications of electricity had a grand future before them. Capital was soon at his disposal, and he founded an important industrial society, of which he undertook the direction.

At this time his prosperity seemed unclouded. At the age of 30 he was known as a scientific man; he was the equal and friend of great scientific notabilities; he was at the head of a prosperous industry. And, besides, in his private life he enjoyed all the pleasures of home. Married to a wife whom he loved, and father of three children, fortune seemed to smile upon him on every side. But the malady which had checked him at the commencement of his career had insensibly made rapid progress. The excess of work during the exhibition had caused general fatigue. He disregarded these warnings, and the fears manifested by his family and his doctor. His moral energy, in fact, the predominant feature in his character, was as strong as ever, and his confidence in himself and his future had even increased. He knew no better than before how to spare himself work. The directing of his firm, the construction of new workshops, the editing of the *Revue*, absorbed his day; the evening he devoted to the preparation of a course of lectures to be given for the first time, at the Observatoire, to the naval officers at Paris. This course was instituted by Admiral Mouchez for the purpose of instructing naval officers in the principal recent discoveries in the domain of electricity.

All these hopes, all these joys, were brought abruptly to an end. The body, worn out by work, became weaker and weaker. In May he was obliged to keep to his room and give up all intellectual efforts. However, his courage and his hope of a speedy cure had not left him, when he died suddenly on the 8th of July.

His death is a cruel loss to his country, to science and to industry.

But his relations, his friends, his workmen, who stood in crowds round his tomb, were at least able to speak of him in these words: "*Antoine Breguet, dead on the field of honour.*"

GLASGOW SCIENCE LECTURES.—Arrangements have just been completed for the delivery of a course of science lectures at Glasgow during the coming winter. On the list of lecturers we observe the name of Prof. Silvanus P. Thompson, who is to discourse "On the Earth as a great Magnet."

CORRESPONDENCE.

TO CORRESPONDENTS.

No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer, not necessarily for publication, but as a guarantee of good faith.

Correspondence should arrive not later than Tuesday morning if it is desired to appear in the following number.

THE TELEPHONE.

To the Editors of THE ELECTRICAL REVIEW.

DEAR SIRS,—I am glad that the pieces of evidence which I have been able to adduce from the original writings of Reis have drawn from Count du Moncel the promise to insert them in the next edition of his book, "Le Téléphone." I must, however, express my surprise that the author of a historic work on the telephone, such as Count du Moncel's claims to be, should have so long done the original inventor of the electric telephone, which "formed the starting-point of all the others," the injustice of not acquainting himself with the *ipsissima verba* of that remarkable man. Compared with the stuff that has been written from time to time about Reis's telephone, the original memoirs of Reis are as clear as daylight. Nor do I think that even Count du Moncel will long be able to withhold from Philipp Reis the honour of having been the first—whether he understood the *theory* of it or not—to transmit articulate speech electrically.

I do not know that it is necessary for me to prove that Reis understood the principle of undulatory currents in order to believe that his telephone would and did transmit speech. I believe that M. Gramme, who invented a very admirable dynamo-electric machine, did not understand the equations of mutual induction, and yet I do not doubt that his machine generates electric currents. But in the case of Reis the diagrams of curves attached to his memoirs conclusively show that he did realise what was to be done, though he only succeeded in finding an imperfect means of attaining it.

Count du Moncel throws down a challenge of fact, which I shall be most happy to accept. He says, and italicises the words himself, that "for sounds to be reproduced by a receiver, consisting of *an iron wire enclosed in a helix, and stretched on a sounding case placed on a table* (the only Reis receiver known), the currents sent by his transmitter must have been *interrupted.*" . . . Why must they? This form of receiver—commonly known as Reis's knitting-needle receiver—will articulate just as well, though not so loudly, as a Bell receiver, if supplied with adequate currents. If Count du Moncel will try the experiment with two or three bichromate cells and a good transmitter, such as Hunnings' or Ader's microphone, he will have a sufficient proof that Reis's receiver *will receive* articulate speech. When Count du Moncel says that with this receiver the currents "*must*" have been interrupted, I simply deny this to be the fact, and reply that if this receiver is to articulate the current *must not* be "interrupted," in the sense of being completely broken.

I am surprised that Count du Moncel does not know of the existence of the other Reis receiver with the electro-magnet in it. My earliest acquaintance with it was in Kuhn's "Angewandte Elektricitätslehre" (p. 1018) in Karsten's well-known cyclopædia, published in 1866. The original description of it is in Legat's report in the "Zeitschrift" of the Austro-German Telegraph Union of 1862. Perhaps Count du Moncel only knows it as Legat's receiver, as I myself for a long time thought it, until I read the original article and found it to be really Reis's.

Again, Count du Moncel says that if Reis had really penetrated the principle of the articulating telephone he could have substituted for the metallic contacts some of moderate conductivity. *Why should he*, indeed? This fallacy—that a semi-conductor is advantageous, first introduced by Edison—has nothing to do with the matter. Take an ordinary Blake transmitter and replace the carbon button by a silver sixpence. It articulates just as well as before. Yet silver is the very *best* conductor. Conductivity, or semi-conductivity, has nothing to do with the matter, and the only advantages of carbon over silver are that it does not fuse or rust at the point of contact; and that, moreover, at the point of contact a minute voltaic arc *may*, in certain cases, prevent complete interruption in the circuit.

Reis did, indeed, penetrate the principle of the articulating telephone: for, as in every practical telephone transmitter in use to-day, so in his telephone transmitter, there was a *loose contact* in the circuit, *so arranged that the voice could act upon it, and thereby regulate the strength of the current.* If you eliminate this part of the apparatus—screw up the loose contacts of your practical telephone transmitters so that our voices cannot affect them—what will your telephones be worth? No, the essential principle of the telephone is *imperfect contact*, and that essential principle was invented and applied for the purpose of transmitting speech by Philipp Reis in 1863.

If this does not suffice as a claim for the invention of the telephone transmitter, I wonder what will. We can dispense with the electro-magnetic receiver, and use other receivers; we can dispense with diaphragms, and tympanums (also Reis's invention, by the way), in the transmitter; we can dispense with semi-conductors, *et id genus omne;* we can dispense with springs and tension-screws: but with the principle of *loose contact* we cannot dispense. That which alone is indispensable, Philipp Reis discovered.

SILVANUS P. THOMPSON.

July 26th, 1882.

THE CITY AND GUILDS OF LONDON INSTITUTE TECHNOLOGICAL EXAMINATIONS, 1882.

To the Editors of The Electrical Review.

Sirs,—The students who sat at the technological examinations held under the auspices of the City and Guilds of London Institute in May last are now aware of their examiners' decisions. These decisions, so far as they relate to electrical engineering, may perhaps, when summarised, not be uninteresting to your readers:—

TELEGRAPHY.

London.........	1										

My chief object, however, in submitting the above schedules to you is to suggest, through the medium of your valuable paper, the desirability of the Institute giving in the annual report the information requisite for the filling up of the blank columns, and thereby rendering the schedules both interesting and instructive.

It is satisfactory, no doubt, to know that 43 students have passed in telegraphy, 27 in electric lighting, &c., and 1 in electrical instrument making; but it would be much more satisfying to know how many candidates attended the examinations, and how many of them were connected with the industry examined on. I feel assured that the utility of such statements would more than repay the little extra labour incurred in their compilation.

It is, perhaps, somewhat early to comment on the results of the examinations with the meagre details at present in our possession, but it may be pointed out that the only two ladies whose names appear on the *Pass List* are connected with telegraphy. This is a gratifying feature, and it is to be hoped that on the next list, not only will these names re-appear, but those of many other fair competitors. The laurels gained for London are a little remarkable. The student examined at Cowper Street takes the place of honour, while the seven students examined at the Central Telegraph station take second-class places in the lowest grade! This is, unfortunately, not an exceptional case, and when taken in connection with the remark in the examiners' last report, that he knew the papers of those engaged in telegraphy, will, it is to be feared, produce a most detrimental effect, so far as telegraphists are concerned, and it can hardly create surprise if the falling off in next year's *Pass List* is even greater than that in the one just issued.

Colonel Webber, in his inaugural address to the Society of Telegraph Engineers, speaking of telegraph engineering, says:—"So blind is the tyro to the realities of practice and to the intricacies of the agent he uses that technically educated men, thrown into the turmoil of the insidious difficulties to be encountered, will break down, and fail even to detect them. In an educational institution such as I have before my mind, I would, if possible, not only allow the *theory* and *practice* to march hand in hand, but I would allow the practice to precede the theory with some minds, and *vice versâ*. The course would thus engage the interest of both kinds of minds, and confer the maximum of benefit. Such an institution should include instruction in the lecture theatre, in the workshop, in the laboratory, &c." This is undoubtedly what should be; but is the consummation likely to be attained so long as the present system of examination prevails? Will students who are more ambitious to win prizes than gain genuine knowledge, and teachers who are more anxious to increase their incomes than impart lasting instruction, give to *practice* the attention which it deserves? No; because payment and rewards are now made not according to useful knowledge, but according to cram, or examinational knowledge; and until steps are taken to make practical examinations go hand in hand with the written examinations this unsatisfactory state of affairs must continue, and such cases as the following, by no means an isolated one, recur.

A student who some five years ago obtained from the Science and Art Department a first class certificate for electricity and magnetism, and who has since devoted the greater portion of his time to the study of technical telegraphy, and discharges from time to time the duties of a testing officer, attended, along with a fellow clerk, whose studies dated from

the close of the preceding year, a recent technological examination, with the result that while the man of six months' study gained an honour's place, the man of six years' theoretical knowledge and practical experience was plucked. For this anomaly the examiner is in no way responsible, his duty being to adjudge the papers submitted to him without partiality; and I bring it forward not to point to any unfairness on his part, but to draw attention to the necessity for practical examinations, for there can be but one explanation of the failure of the man who is familiar with the laws of electricity and who applies them daily in the discharge of his duties, and that explanation is his inability to express himself on paper with such clearness as to warrant his examiner in granting him a place on the Pass List.

As the subject is one of considerable interest I leave it to be discussed by those better qualified than

Yours truly,

July 28th, 1882. FAREHAM.

ELECTRIC LIGHTING IN THE CITY.

To the Editors of THE ELECTRICAL REVIEW.

DEAR SIRS,—With reference to the notices which have recently appeared in your journal, giving certain figures as to the electric lighting in the City, I beg to state that these statistics, as given, may be very misleading without explanation, as they do not by any means convey to the general reader a fair understanding of the subject. The apparent high percentage of so-called "failures or extinctions" shown as to the Brush light is almost wholly due to the fact that the lighting was discontinued from the 2nd May, 1881, for a period of seventeen days, it having been determined, in consequence of defects which soon appeared in the first cable laid down, to replace it with another. This, surely, should only be estimated as a single failure (one, too, which had nothing to do with the Brush system, and which could be guarded against for the future); whereas it is reckoned, in the figures given in your article, as 561 failures, counting each of the 33 unlighted lamps as one failure for each of the 17 nights during which no lighting was even attempted. This reduces the reported 660 failures to exactly 100, the whole of which arose from causes which (after the experience gained in this the first large attempt ever made at street lighting in this country) are easily remediable. It is worthy, also, of notice that, although the lamps in question are all on a single circuit, in no case has an accidental stoppage of the mechanism in one lamp affected any of the others. The 209 hours 30 minutes extinction, through the failure of the driving apparatus, occurred at the commencement of the trial, when some necessary alterations were being made in the arrangement of the boilers and other machinery at the factory.

It should further be pointed out that the number of so-called failures was considerably increased by one of the lamp-posts being overthrown by a van, causing an extinction of this lamp for 103 hours. Deducting, then, from the gross extinction of 3,142 hours 30 minutes, 2,630 hours for relaying the cable, 103 hours for the broken lamp-post, and 209 hours for the alterations to boilers, &c., which events are altogether outside any defect in the Brush system of electric lighting, there remains only 200 hours of extinction, spread over a series of 33 lamps, out of the total number of 141,900 lighting hours, being a percentage of ·14 during the whole year of an experimental running, the first of its kind ever attempted in this country. I would further point out that of these defects the bulk were in the early part of the experiment, and that they have gradually become less and less, pointing to the conclusion that with a little more time and experience we may expect that they will disappear entirely.

Since the continuation of the lighting for the second year the lamps have burnt very regularly, and, so far, we have had no complaints.

I would mention that the subject is very fairly and comprehensively dealt with in the report of the Streets' Committee, presented by Colonel Haywood, a copy of which appeared in *Engineering* of July 14.

Yours faithfully,

JAMES HUMPHREYS.

London, *Aug. 3rd*, 1882.

[We take pleasure in inserting Mr. Humphreys' interesting letter. He has, however, apparently overlooked the source from whence we derived our figures, viz.: the report to the Streets Committee, to which he alludes in his letter. Mr. Humphreys seems not to have read the article in our contemporary carefully, or he would notice that the analysis of the failures is not from the pen of Mr. Haywood. We cordially agree with our correspondent that with more time and experience defects which now exist should disappear entirely.—EDS. ELEC. REV.]

NOTES.

CRYSTAL PALACE INTERNATIONAL ELECTRIC EXHIBITION, 1882.—The directors have pleasure in announcing that they have received from the jurors the following award of prizes:—

DIPLOMAS OF HONOUR.

AWARDED TO EXHIBITORS NOT COMPETING FOR TRADE MOTIVES.

Her Majesty's Postmaster-General.
The Secretary for War.
The Anglo-American Telegraph Co.
The Eastern Telegraph Co.
The Telegraph Construction and Maintenance Co.
The Submarine Telegraph Co.
The South-Eastern Railway.
The London, Brighton, and South-Coast Railway.

For the general excellence of their exhibits.

C. F. Varley.—For his induction machine and condensers.
R. H. Froude.—For dynamometer.

GOLD MEDALS.

J. R. Voss.—For induction machine.
Elkington & Co.—For their deposition of gold alloys and general excellence.
H. Wiggin & Co.—Improvements in electro deposition of nickel and cobalt.
The Faure Electric Accumulator Co.—For Faure battery.
T. A. Edison.—For complete system of lighting and other exhibits.
British Electric Light Co.—For Gramme dynamo machine and exhibit.
R. E. Crompton.—For Bürgin dynamo machine and Crompton arc lamp.
Anglo-American Brush Co.—For Brush dynamo machine and arc lamp.
Swan's Electric Light Co.—For incandescent lamp.
Electric Light and Power Generator Co.—For Weston and Maxim dynamo machines and lamps.
White House Mills.—For dynamo machine.
Rowatt and Fyfe.—For Pilsen arc and Joel semi-incandescent lamps.
G. G. André.—For arc lamp and regulator.
Gérard & Co.—For arc lamp.
Davey, Paxman & Co.—For steam engines.
Galloway & Sons.—For steam engines.
Marshall & Co.—For steam engines.
Robey & Co.—For steam engines.
Ransomes, Head, and Jefferies.—For steam engines.
Hornsby and Sons.—For steam engines.
E. S. Hindley.—For steam engines.
Crossley Brothers.—For Otto gas engine.
Thomson, Sterne, & Co.—For Clerk's gas engine.
Roos and Ostrogovich.—For their application of the automatic system to Hughes' type printing apparatus.
Johnson and Phillips.—For the general excellence of their exhibits.
Direct United States Cable Co.—For the excellence of their exhibits.
Edward B. Bright.—For his fire alarm system.
The Exchange Telegraph Co.—For the general excellence of their exhibits.
Professor Dolbear.—For his new electrostatic telephone.

SILVER MEDALS.

Coxeter & Sons.—Class X.
W. Elmore.—Class XI.
United Asbestos Co.—Class XIII.
J. & H. Gwynne.—For steam engines.
Fyfe & Main.—For arc lamp.
National Electric Light Co.—For dynamo machine and lamps.
Gravier & Co.—For arc lamp and exhibit.
R. Hodson.—For steam engines.
Hammond Electric Light Co.—For installation of Brush machines and lamps.
A. Cance.—For arc lamp.
Domestic Electric Lighting Co.—For the general exhibit.
Electric Lighting Supply Co.
Electric Lighting Engineering Co.
Strode & Co.
W. Ladd & Co.—For early historical dynamo machine.
W. J. Hammer.—For historical collection of incandescent lamps.
W. T. Henley.—For his cable core.
W. R. Sykes.—For his electric locking and blocking system of railway signals.

The Consolidated Telephone Construction and Maintenance Co.—For the general excellence of their exhibits.
Saxby & Farmer.—For their railway signals.
R. Johnson & Nephew.—For their iron wire exhibit.
F. Smith & Co.—For their iron wire exhibit.
R. S. Newall & Co.—For the general excellence of their exhibit.
W. T. Glover & Co.—For the general excellence of their exhibit.
Phillips Brothers.—For the general excellence of their exhibit.
Professor Monnier.—For his detector and analyser of fire damp.
J. W. Gray & Sons.—For the excellence of their exhibit.
Sanderson & Co.—For the excellence of their exhibit.

BRONZE MEDALS.

Binko & Co.—For their improved agglomerate battery.
E. Dent & Co.—For their non-magnetising watches.
E. Paterson.
G. Skrivanoff.—For his dry battery.
R. Webster.—For his non-magnetising watches.
Roth, Sohlaefli & Co.—For their electric self-winding clocks.
J. F. Pratt.—Class X.
H. Whiteside Cook.—For his electric governor for screw marine engines.
Arnold & Sons.—Class X.
L. H. Borrell.—For electric self-winding remontoire clock.
T. R. Brailsford.—For water-level indicator.
J. Storer.—For electrical table fountain.
J. Willing.—For electrical signs.
B. Verity & Sons.—For brasswork.
G. Hawkes & Co.
Zanni & Co.
E. Müller.
E. Blouzon.
C. R. Goodwin.
Mignon & Co.
J. E. Liardet.
A. R. Sennett.
J. H. Athole Macdonald.
Philadelphia Dynamic Co
Alfred Apps.
J. E. and S. Spencer.
Julius Sax.
W. Groves.
Doulton & Co.
Automatic Telegraph Co.
J. Davis & Co.
School of Submarine Telegraphy.
Electric Railway Signal Co.
G. C. Lewis & Son.
Waterlow & Sons.

W. GARDINER,
Secretary.

Crystal Palace, *July 24th*, 1882.

THE AWARDS AT THE CRYSTAL PALACE ELECTRICAL EXHIBITION.—We fancy that a considerable amount of surprise, if not of something stronger, will be felt by the majority of the exhibitors at the recent Electrical Exhibition upon perusal of the lists of awards. We will not say anything of the Diplomas of Honour, as they do not enter the question. The awards of the medals (gold, silver, bronze) are, however, open to comment. We notice that Mr. Crompton is the possessor of a gold medal for the Bürgin dynamo-electric machine and the Crompton arc lamp. Messrs. Fyfe and Main must needs be content with a silver award for the Standard Fyfe-Main lamp. These latter gentlemen were dependent upon a Gramme machine for the production of the electric current, and Mr. Crompton had also to rely on another man's invention for his supply of current; therefore, we cannot think that the one should be credited with a higher degree of excellence than the other, if the two merits of the lamps are considered. Mr. Crompton, certainly, manufactures the Bürgin machines, and his exhibit was complete long before that of Messrs. Fyfe-Main; and, all things considered, the jurors may have had their reasons for the decisions given. The White House Mills Company receive a gold medal for dynamo-electric machines. This exhibit was, certainly, one of the most attractive of all—in a way that our readers will well understand. We, ourselves, never visited the Palace without making a mental note of the progress made, and the results obtained, at the stand of the White House Mills Co. It is still more surprising to note that Mr. E. Paterson, Messrs. Verity and Sons, the School of Submarine Telegraphy, and others, are favoured with bronze medals only. Messrs. J. and H. Gwynne and Mr. R. Hodson will doubtless appreciate the discernment displayed by the jurors in awarding to them silver medals for their fine specimens of direct-acting engines. Many of the recipients of silver and bronze awards will probably regret that they did not follow the example of Messrs. Siemens Bros. and retire from the competition. In our issue of the 8th April we expressed an opinion that the appointment of jurymen to report upon the comparative merits of the Electrical Exhibition was a mistake. We think that many of the exhibitors will now agree with us, that it would have been better to leave the Press and the public to make their own criticisms. We reprint above the report of the jury.

THE FINANCIAL RESULTS OF THE CRYSTAL PALACE ELECTRICAL EXHIBITION.—According to the report of the directors of the Crystal Palace, the receipts, compared with the corresponding six months last year, show an increase of £18,991. Comparing the expenditure, there is a diminution of £3,354. The number of visitors have been considerably in excess of the largest number that have attended the palace in any half-year since the opening.

ELECTRICAL EXHIBITION AT THE ROYAL AQUARIUM.—In our "Notes" of the 22nd ult., we called attention to the above proposed exhibition. In our supplementary pages today, further particulars of interest to intending exhibitors will be found. The building seems quite suitable for the new venture of the Aquarium management, and it reminds one, both in size and shape, of the Palais de l'Industrie, in Paris. It has a great advantage in being easily accessible from all parts of London.

SCIENTIFIC REPORTS ON ELECTRIC LIGHTING.—We extract from the "Money Article" of last Monday's *Standard* the following letter:—

Sir,—In your issue of Monday, the 24th instant, a letter of Professor Gordon appeared, and it could have only been written to injure, which I feel is not your wish. As a fact to base from, the patent I took out for the division and subdivision of the electric current was the first, and before this, it was viewed, not only by practical electricians, but the public and the press, that the electric light could never be used for domestic purposes until some means was devised to that end. I was given to understand that Professor Gordon himself was a worker in this direction, in what way I do not know, never having inquired, but certain it is that the means I had worked out and secured the patent for he was the first to veto. Another fact worthy of notice is that at the Paris Exhibition my appliances were not used, but many that exhibited at Paris made free use of my invention at the Crystal Palace to demonstrate facts they could not do at Paris. Between these exhibitions my patent became a public document, and the interest shown in the question speaks for itself by the first issue of the patent books being eagerly bought up and a second edition having to be published. The means I have devised are known to be simple, and many companies are using them, and abusing the inventor to cover their doings. A reckoning must come about sooner or later, but legal technicalities at present bar the way.

It may be well to state how Mr. Gordon came upon the scene. He was commissioned by gentlemen who contemplated forming a company on my inventions to inspect and report on the incandescent lamp I had produced. When he came he distinctly stated his mission—to see as to the merits of my lamp. He tested one at my works; others were sent to an address he gave. He gave a report and was paid his fee. It seems he offered some gratuitous remarks relative to the subdivision, which I have seen since in his letter to the press.

You and the press in general have from time to time noticed my doings in this question, and I think I may fearlessly say I am the only person (firm or company) that has allowed free inspection of my works from the engine-room to the burning of the lights, the making of the filament to the mounting, the glass blowing, the division and subdivision of the electric current—in fact, all that tends to show the system; and my visitors' book bears attestation by signatures of men of known repute of all nationalities sufficient to convince any person that what Mr. Gordon assumes has no weight.

In conclusion, I would ask, may I invite the public through your columns to come and see for themselves how far I have met the question of lighting by electricity the cottage or the mansion, and thus judge between demonstrated fact and scientists' opinion; for Mr. Gordon has not, even as one of the public, visited my works during the six months I have kept open show-rooms on the Viaduct more than the occasion referred to, than having a lamp taken down and testing it. I, therefore, leave the public to judge between us.

I am, Sir, the public's obedient servant,
JOHN BANTING ROGERS.

47, Holborn Viaduct, *July* 29, 1882.

We have often wondered why Mr. Rogers has kept o unaccountably in the background as far as letter-writing is concerned, but we no longer wonder why he has hidden his "light" under a bushel in the face of this effusion. Such a silly and unmeaning epistle we have rarely had the misfortune to peruse.

We deal in our other columns with the *invention* of Mr. Rogers for the division and subdivision of the electric current.

The idea of producing a visitors' book to convince any person that Mr. Gordon's opinion has no weight is novel and

amusing, and shows that Mr. Rogers is *really* endowed with inventive faculties.

It will be remembered that in our "Notes" of last week we published Mr. Gordon's letter to the daily press and also the reply to it from the solicitors of the J. B. Rogers Company. Mr. Gordon has again taken up the matter, and the following appeared in Wednesday's *Times* :—

July 27th, 1882.

SIR,—I observe in the *Times* of Tuesday last a letter purporting to have been written by Messrs. West, King, Adams, and Co., in reply to mine of the 21st inst.

Will you kindly permit me to say that I never sent a draft report to any one, and that it is not the fact, as stated by your correspondents, that I struck out of my report the part relating to the system.

The facts are as follows: My report was dated and sent in on the 3rd of June, and consisted of two parts, one having regard to the lamps, the other to the system. Subsequently, at the request of the gentlemen interested in the formation of the company, and upon the understanding that they would organise a company to manufacture the lamps, and would abandon the system, I divided the report into two parts, both being signed by me and left with them.

At an interview on the 9th of June with the then intended directors I found that they were unaware of my report on the system, and at the request of the then intended chairman I, on the same evening, sent him a copy of it. He duly acknowledged its receipt, and stated that he would read it to his colleagues.

I heard nothing more of the matter until on the 10th inst. the advertisement of the company came out, and it then appeared that of the nine gentlemen whose names on the 9th of June were printed on the proof prospectus as directors only one remained, and that the system was put prominently before the public.

My report was not quoted until July 20th, the day of the closing of the lists. I should not, however, have entered upon this correspondence if either my report on the system had been accessible to the public or the system had not been referred to in the prospectus.

I enclose a list of the Board of Directors as constituted on the 9th of June for your information, but, for obvious reasons, not for publication.

I am, Sir, your obedient servant,
J. E. H. GORDON.

ELECTRIC LIGHTING CONTRACTS.—We are asked to state that the Metropolitan (Brush) Electric Light and Power Company Limited has secured contracts to light up the Royal Mint, the premises of Messrs. Halling, Pearce, and Stone, and the Floral Hall, Covent Garden.

ELECTRIC LAMPS WITH CARBON FILAMENTS.—We were correct in assuming last week in a note on the above subject that the Edison Electric Light Company would probably have applied, before the ELECTRICAL REVIEW was issued, for an injunction to restrain the Swan United Electric Light Company from infringing the Edison patents. On Friday morning the 28th ult. the case was brought before Mr. Justice Chitty, when the defendants challenged these patents, and it was arranged that the motion should stand till the trial of the action, the defendants undertaking to keep an account. We understand that only one patent is involved, that dated 10th November, 1879, No. 4796. The Edison Company, we believe, seek to restrain the defendants from "making, selling, or using any electric lamp made according to or in the manner described in the specification filed in pursuance of the said letters patent, or according or in any manner only colourably differing from the same." With regard to the Swan lamp, we think we are correct in stating Mr. Swan's contention is, that the carbon filament is not made or secured to metallic wires as set forth in the above patent (10th November, 1879). We believe it will also be part of the defendants' case to endeavour to show that Edison's patent is void by reason of prior publication and also of insufficient description. We cannot foretell the ultimate result of this trial, but we hear that before bringing their action the Edison Company asked the defendant company to keep an account, &c., and this was declined. Of course, had the Swan Company so agreed, the Edison Company might have said that the defendants had given in. As the case now stands, however, it allows the defendant company to state that the motion for an injunction has failed.

THE YORKSHIRE BRUSH ELECTRIC LIGHT COMPANY.—We have received information that The Yorkshire Brush Electric Light and Power Company (Limited) is about to establish a large central lighting station at Middlesbro', for the purpose of supplying the electric light to the various iron works on the marshes. The entire scheme will be carried out under the direction of Mr. W. Kingsland. This gentleman will be remembered by our readers as having had charge of the lighting of Chesterfield, by the Brush "Arc," and Lane-Fox incandescent electric lamps. A full description of this installation was given in the ELECTRICAL REVIEW of April 15th.

THE PHŒNIX ELECTRIC LIGHT AND POWER COMPANY.—In the Chancery Division of the High Court of Justice, before Mr. Justice Chitty, on Saturday last, a petition presented by Messrs. Foster, Hight & Company, accountants, who were creditors for the winding up of the Phœnix Electric Light and Power Company, was by arrangement dismissed.

THE ELECTRIC LIGHT IN THE CITY.—In a leading article entitled "The Mysteries of Electric Lighting," the *City Press* says:—"If the Brush Company, after twelve months' experience, can light with their system, *at a profit*, for £800 a district of the City that was formerly lighted with gas at a cost of about £700, why do they refuse to tender for lighting the rest of the City at a price that would produce them a very large profit, and yet doubtless be readily accepted by the Streets Committee? The calculation has been made that the price they charged for a light, equal to a hundred (?) candles, burning for twelve hours, was three farthings. If this can be done at a profit, no one will be more astonished than one of the most eminent electricians of the day, who, when asked the question, answered in the classical language of Goldsmith, Fudge!"

SPEED OF WORKING THROUGH CABLES.—Mr. John Pender, the Chairman of the Globe Telegraph and Trust Company, made a curious remark in the course of his speech at the above company's meeting last week. If correctly reported, Mr. Pender said, speaking of a new Company: "But as for the cable they intend to put down, it would be simply impossible for them to do their work. They assume that they will do twenty-five words a minute. Sir James Anderson, who has had great experience of what the *best manipulators* [the italics are our own] can do, will tell you that sixteen words a minute is uncommonly good work. Therefore the whole statement throughout is one that, I am sorry to say, shows the greatest ignorance on the part of those who concocted it, and I think it is using a mild phrase to call it ignorance. Probably they would not be able to work their system at more than ten words a minute." We have hitherto been under the impression that the speed of transmission through cables did not depend upon the manipulator, but rather upon the various retarding influences inherent in all long submarine lines. To the best of our knowledge the speed of working through the 1865 and 1866 Atlantic cables attained the rate of seventeen words each. Mr. Pender could probably tell what this means if the cables were employed for *duplex* working. We have reasons for believing that those responsible for the statement concerning the speed of transmission through this proposed new cable are, perhaps, the most experienced and capable men we could name for this class of electrical engineering, and that they know exactly what they are talking about.

EXTENSION OF THE NETWORK OF FRENCH CABLES ALONG THE NORTH COAST OF AFRICA.—The India-rubber, Gutta-percha and Telegraph Works Company have contracted with the French Government for the making and laying of 260 nautical miles of submarine cables and, as stated in the general meeting of the 25th ult., it is the intention to lay this cable with their ss. *International*, which is now on her homeward voyage from the West Indies. The cable is to be laid along the Coast of Tunis from Soussa to Sphax, and from Sphax to Gabes, or Kabes. The town of Soussa, or Susa, is situated on the coast 4½ miles from Ras al Marsa, rising gradually from the shore to the citadel at the south-west, within which is a conspicuous tower elevated 260 feet. The walls surrounding the town are from 30 to 40 feet in height, having bastions and towers at the several angles. Upon either side of the town are well wooded ridges, dotted with houses. The town has a particularly white appearance. Soussa contains several handsome mosques and well kept bazaars, and has manufactories of linen, with an active trade

in oil, wood, pottery, shoes, &c. The population is said to be about 10,000, and a British Vice-Consul resides in the town. The ruins of the ancient port are still visible. It was formed between two moles to the northward of the present town, but is now so filled up with sand as to afford but slight shelter even to boats. The southern mole projects nearly two cables from the shore, and has on its outer extremity an exposed battery of 12 guns.

Sphax, the ancient "Taphrura," is enclosed within high walls, is well built, having paved streets, and is reputed the prettiest town in the Regency. When nearing Sphax by sea a high tower and minaret form conspicuous objects. The country around for about five miles is studded with detached houses and gardens, well wooded and backed by a range of hills at about nine miles distant. Sphax contains manufactories of linen, and boats for the coasting trade are also constructed here. It carries on an active trade with Malta and Sicily in oil, esparto grass, sponges from the adjacent islands of Kerkenah, carilla, wood, and barley; fruit and vegetables are grown in the surrounding district. Cucumbers, locally called "sfakous," are said to give the name to the town. Rain falls only in winter, and the heat is tempered by a sea breeze throughout the day. The population of the town is about 6,000 inhabitants.

Khabs or Kabes is a town said to be of considerable size, situated a little within the coast upon the river or Wady Rif; there are a good many surrounding villages, and an active trade is carried on with Tunis, &c. A principal article of commerce is the red dye, called hennah (*Lawsonia inermis*), the plant from which it is procured being extensively cultivated in the neighbourhood. The town is defended by a well-built fort or tower. The port, which has not more than three or four feet of water, is formed by the mouth of a small stream running through the village of Jara.

ON THE APPEARANCES OF THE ELECTRIC ARC IN THE VAPOUR OF THE SULPHURET OF CARBON.—By MM. Jamin and G. Maneuvrier.—We made known to the Academy in the session of June 19th the modifications which the electric arc undergoes in the pneumatic vacuum when it is produced by a Gramme machine with high-tension alternating currents. We have found that the phenomena are modified if gases or vapours are introduced into the glass in which the experiment is made. These phenomena are very remarkable in the vapour of sulphuret of carbon.

The burner used in these experiments is formed of two vertical parallel carbons fixed at their base; the upper extremities, which are opposed to each other, can be brought into contact or separated by a simple mechanism. The apparatus is placed under a large bell of the pneumatic machine, and is exhausted as completely as possible. Under such circumstances the arc is not formed, but in its place there appear the lights of a Geissler tube. On introducing into the bell a few drops of sulphuret of carbon, so as to obtain an increased pressure of 0·05 to 0·06 metre, we see the arc enkindled between the points, and remain burning when they are withdrawn from each other.

At this moment there is, as it were, an explosion of light so bright as to be insupportable, and incomparably superior to the ordinary lustre of the arc. On examining it through darkened glasses, we see a brilliant arc of 0·05 to 0·06 metre in height, resembling a horse-shoe, or a capital Omega. The two extremities are at the two points of the carbon, and there is besides a long flame, like that of a furnace, which plays over the arc, escapes from it, and ascends vertically.

The points of the two carbons appear red and very brilliant, but the arc is of a pale green, and as its light overpowers that of the carbons, all the room is illuminated with this tint. The splendour increases so as to become intolerable as the tension of the vapour increases, but as the resistance of the vapour increases at the same time, the arc is often extinguished, and requires to be re-kindled every moment, by bringing the carbons in contact.

On examination with the spectroscope, this light presents all the rays of the carburetted gases in combustion, but more complete and better defined. The spectrum is very discontinuous. At its red extremity is a striped spot; first a very bright line followed by several others, more slender and close together, then a broader line which repeats the former, and which is also followed by fine rays; these appearances are repeated as we proceed towards the orange, but becoming fainter until they disappear. After a dark interval the same appearances are repeated in the yellow, and in the beginning of the green; then follows another dark interval, succeeded by a repetition of the same effects in the green, and finally in the violet.

To sum up, the spectrum is composed of four striped portions in the red, the yellow, the green, and the violet, so identical that, save for the colour, they might be taken for the same pattern transported from the red towards the violet. It is very probable that they obey one and the same harmonious law which remains to be discovered.

Of these four regions the green is much the most luminous, and gives the special tint to the arc, and colours all objects green.

Whilst these appearances are manifested a chemical action is produced. If air remains in the bell, and if the apparatus is not well closed, the sulphuret of carbon burns imperfectly; a cloud of sulphur fills the bell, and is deposited on the sides, whilst the carbon burns alone. If the air has been well exhausted, these clouds are not formed, but a brown deposit is fixed upon the sides, becomes black, adheres to the glass and dims it. This deposit is volatile, and has an odour resembling that of sulphur.

It is evidently a compound of carbon and sulphur, perhaps a proto-sulphuret corresponding to carbonic oxide, perhaps an isomeric modification of the ordinary sulphuret. We see, indeed, no deposit either of sulphur or carbon, and the pencils of the burner have neither lost nor gained anything. It is probable that the sulphuret of carbon is dissociated, the sulphur volatilised, the carbon diffused in vapour in the arc, and that this carbon and sulphur recombine in the flame to reconstitute a compound under different conditions: but this is mere conjecture not yet analytically demonstrated.

This experiment is remarkable for the extraordinary quantity of light produced, for the magnitude of the arc, for its colour, the character of its spectrum, and the chemical reactions which take rise. It will not probably be available for lighting on account of its colour, except for lighthouses, or for signals to a distance.—*Comptes Rendus*.

NEW COMPANY REGISTERED.

STANDARD TIME AND TELEPHONE COMPANY (LIMITED).—Capital £100,000, in £1 shares. Objects: To acquire and work inventions having reference to the transmission and regulation of time or timekeepers by electricity or otherwise, and for the accumulation and dispersion of electric currents; also to carry on the usual business of a telephone company, and to manufacture electric, magnetic, and pneumatic appliances of all kinds. Signatories (with five shares each): P. J. Morrison, St. Albans; E. Ray, 5, Percy Street, Bedford Square; E. A. Bacot, 35, Oakfield Road, Clapton; R. W. Cole, 153, Hemingford Road, N.; F. Bigg, 39A, Threadneedle Street; J. Usher, 25, Barnsbury Park; E. S. Parker, 75, Cornhill. The signatories are to appoint the first directors and determine their remuneration. Qualification, 1,000 shares. Registered 26th of July, by Newman and Co., 75, Cornhill.

NEW PATENTS—1882.

493. "Preparation and manufacture of asbestos as an insulating material for electrical apparatus and for other purposes." C. J. ALLPORT. Dated February 1.

3557. "Telephonic appliances." J. MUNRO and B. WARWICK. Dated July 27.

3570. "Electric arc lamps." F. M. NEWTON. Dated July 27.

3575. "Electric lamps." J. G. LORRAIN. Dated July 27.

3576. "Improvements in distributing and measuring electricity and in apparatus to be employed for those purposes." J. HOPKINSON. Dated July 27.

3582. "Improved means of regulating electric currents and electromotive force and apparatus thereof." L. CAMPBELL. Dated July 28.

3583. "Electric lamps and machinery and apparatus connected therewith for obtaining and transmitting power." W. T. HENLEY. Dated July 28.

3591. "Electric producer and power machines." J. IMRAY. Dated July 28.

3592. "Secondary batteries." F. J. BOLTON. Dated July 28.

3595. "Electric telegraph and apparatus employed therein or connected therewith." J. H. JOHNSON. (Communicated by E. Estienne.) Dated July 29.

CITY NOTES.

Old Broad Street.

THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED).

On Thursday an extraordinary general meeting of the shareholders of this company was held at the City Terminus Hotel, Cannon Street, under the presidency of Sir Henry Tyler, M.P.

The secretary, Mr. W. J. Cordner, having read the notice convening the meeting,

The Chairman said: Gentlemen, as you have seen from the notice, our only business to-day is to confirm the resolution passed on the 18th July. The meeting is, therefore, called in accordance with the 51st clause of the Companies' Act, 1862. In accordance with that we have summoned you within a month, and also within more than fourteen days from the last meeting, to ask you to confirm the resolution which you passed on the 18th July. I do not think, as I stated fully on that occasion the object of the resolution—I do not think I need detain you on the present occasion at any great length. It is simply to enable us to distribute amongst you the sum of £245,000, which we hold at our disposal, and for which we have had warrants prepared, so as to be able to furnish you with the very satisfactory interim dividend of 100 per cent. upon all you have subscribed upon this undertaking. I beg to move this resolution: "That the 85th of the Articles of Association be repealed," and that in lieu thereof the following be henceforth adopted as the 85th Article:—"The directors may from time to time, on their own authority, pay to the members, in proportion to the amounts paid up or credited as paid up, on shares held by them respectively, such bonus and such interim dividend as, in the judgment of the directors, the position of the corporation justifies."

Mr. Scudamore Sellon: I will second that.

Mr. Hammond said before the chairman put that to the meeting he should like to say one word. Of course the resolution deals with the distribution of dividends, and those who hold shares in the company were glad to hear that 100 per cent. was being declared in that way; but it did not quite rest there. When shareholders received a dividend they were glad to have an idea of how the dividend was being earned (hear, hear). He thought it was well within the province of the meeting just to ask the directors, through the chairman of the company, to give a slight hint to the shareholders in that respect. He thought it desirable for more than one reason. They were told outside that this company, with which, as some of you know, I am vitally connected——

The Chairman: I think you are also engaged in another company?

Mr. Hammond replied that he had been careful to put it that he was vitally interested in that present company. The policy of the Brush system had been to cover the whole of England with sub-companies, working enthusiastically in various parts of the country. When first he had the pleasure of being connected with this company the Brush system was not so widely known in England as at the present time. He did claim, in spite of the call to order by the chairman, that he was vitally interested in this company. The Brush machine had been placed by him in a place where it was before unknown, and he was daily engaged in pressing forward the fortunes of the Brush system. The shareholders would see, and those outside that room, outside that company, would see that there are those who ignorantly assume that no profits were being made by the company in their manufacturers' branch. They were told that the declaration of a 100 per cent. was simply made by selling sub-concessions. The policy of sub-concessions had been held up to ridicule. They were told most distinctly that the company was losing money in its manufacturing branch. Therefore, although the shareholders were glad to receive 100 per cent., or a bonus, or whatever it was called, he thought they were entitled to have a hint as to whether the 12½ per cent. declared beforehand in the working branch would not become a mere bagatelle compared with the amount likely to be declared, which was at the present time being earned in that direction. There were outsiders who were constantly assuring the public that the whole thing was a sham. He was personally passing on orders to the company. He thought they had yesterday the invoice of five forty-lighters, a machine which had not been touched previously by any other company. While he was personally passing on those orders, he felt that all the sub-companies were doing the same, he thought there would be no objection on the part of the board to say a word to the shareholders and to those who are interested in the Brush system that the company is in a solid position, irrespective of the money earned out of those concessions, and which they might make in the future, and that behind all this business there is a question of giving not only 100 per cent. to-day but another to-morrow (applause).

Mr. Baker said he endorsed the remarks made by Mr. Hammond, and he should like to ask if the chairman could conveniently give them some idea of the large amount of concessions which would be retained because, of course, they were receiving a very fine bonus or dividend, and there might be good things to come by the end of the year or this time next year. If it were convenient he should like to have some idea of the amount. They had to supply them with the future of the company.

The Chairman replied that he did not know that the remarks made had been strictly in order. The proposition he had made was a very simple one: that the articles of association should be altered for a particular purpose. At the same time he was always ready to go out of his way, though if transgressing the rules of order on occasions when it was desirable to do so, to legitimately give information to shareholders. As to Mr. Hammond's remarks, it was true that they had formed a great number of sub-companies, and they did so with this idea: We said to ourselves, the introduction of this system of electric lighting, or any other system, over the United Kingdom, but also over a great number of foreign countries, is a gigantic business. It is not a business that such a limited capital as we possess can possibly undertake; and therefore, in order that this business may be properly transacted, it is desirable for us to engage other companies with us in this great work, and in order to do that we will, at a reasonable price, sell concessions to different parts of the United Kingdom, and sell our patents to those foreign countries where we have patents. We may as well induce a great number of people to come to work with us in forming the business; we will do our part in manufacturing the apparatus, while they do their part in making installations and applying the apparatus. Well, unfortunately, instead of the business being conducted in an entirely reasonable manner, as they hoped when they started, they had found it had led to a considerable amount of speculation; and that whereas they sold at reasonable prices when they started—and he might say that Mr. Hammond had been instrumental in selling those concessions and in working the business—they found people came crowding upon them and buying those concessions, and that enhanced their values; and complaints were made between one and another that they could not get all they wanted; and not only so, but people to whom they sold, with the only object of starting in different districts, began to sell sub-concessions, till they saw less of the lighting work done and more of the sale of sub-concessions than they could wish. That he took to be a rather unhealthy state of things. And not only so, but the value of their shares ran up to a very high price indeed; there was a sort of mania for buying these things. The board thought that a disadvantageous business. They hoped to see it reasonably conducted. However, they must take things as they were. He was very happy to inform them, as far as he could, their position. The shareholders knew they, the board, only made up their accounts once a year. They had now no annual balance-sheet to lay before them on that occasion. When Mr. Hammond said that people, ignorantly assuming certain things, considered the whole thing a sham, and wanted to know where their dividends came from, he could only say that those on that side of the table could only smile at such an expression. They would be glad to show their works, and be happy to show them to any shareholder who wished to look over them. There was a very large amount of work being performed in manufacturing apparatus. The company had no less than 800 men employed in the business. In fact, their manufacturing profits for the last six months had been £30,000 (hear, hear). Whether that was the worst or the best half he was not going to prophesy. When Mr. Baker got up and asked what would be the profits of the next half-year, he thought it was a little more than he could tell.

Mr. Baker remarked that he did not ask what amount they were about to receive, but what they had received for the sale of sub-concessions.

The Chairman added that he did not think on that occasion that he ought to answer that any further than at the last meeting. On reviewing their balance-sheet, they determined to divide the amount of £245,000; and in order to protect themselves they had taken care that there should be a considerable margin in hand, and, under all the circumstances, that was the amount the board now divided amongst the shareholders. As to going further into the question of what amounts were in hand at the end of the half-year, and what amounts were likely to be earned, he could not go into that question at all.

Mr. Wood asked if the first or second six months of the year were the most productive?

The Chairman said that that was prophecy again. He believed that the second half of last year had been most productive, but that did not prove anything regarding this year. It would depend on the orders received, and the consequent profits.

Mr. Wood said that he should be glad if the board could have taken the *bona fide* shareholders more into their confidence, and so endeavoured to dispel some of those rumours regarding the company. He was sorry to see that their stock had been made the subject of

speculation on the Stock Exchange, and that tended very much to undermine the confidence of the *bona fide* holders. If they could be taken more into their confidence it would be more agreeable to those who were not speculators but shareholders.

The Chairman said that they were taken entirely into their confidence. As to their shares being the subject of speculation, really the directors had nothing to do with that; and in everything that he had said he had tried to stop that speculation. It was very much to their disadvantage that that should go on, and it was the fault of the gentlemen who chose to speculate and thus run their shares up to what he thought too high a price. It was not for them either to sustain or depreciate the stock. They had nothing to do with it, and did not want anything to do with it. He had been the more guarded on this occasion because of the mania for speculation, and he would not say either one way or another one word that would help that speculation either to put up or put down the value of the stock. That was the reason why he had determined to be so guarded in what he said. If Mr. Wood could suggest any figures that might be given that would be of any use with regard to their past history he should be glad to supply them; but as to what might happen in the future he must decline to speculate.

A shareholder asked whether the greater portion of the money which it had been stated they had received for concessions was represented by cash, or whether it was made up of paid up shares with the subsidiary companies.

The Chairman said that was a perfectly legitimate question, and he had no hesitation in saying that they held a large proportion in paid up shares of the subsidiary companies which they had taken instead of cash, and which they were obliged to take in many cases.

The resolution was then put to the meeting, and unanimously adopted.

On the motion of Mr. Henry Maudsley, a vote of thanks to the chairman was carried by acclamation.

The Chairman briefly responded, and the proceedings terminated.

EASTERN TELEGRAPH COMPANY (LIMITED).

On Thursday last an extraordinary general meeting in connection with the above company was held at the offices of the company, 66, Old Broad Street, Mr. John Pender, M.P., presiding, for the purpose of confirming a special resolution, which was passed unanimously at a general meeting held on the 13th ultimo.

The Secretary, Mr. George Draper, having read the notice convening the meeting,

The Chairman said: Gentlemen, as you are aware this is a special meeting for a special purpose; and that is to move the confirmation of the resolution which was passed at the previous general meeting of the company. I shall therefore call upon the secretary to read that resolution.

The Secretary accordingly read the resolution, which was as follows:—

Resolved—A. That the board of directors be, and are hereby authorised from time to time to create and issue mortgage debenture stock of the company to an amount not exceeding one-third of the share capital of the company for the time being issued and paid up, upon the terms that the aggregate amount of the said stock for the time being in issue, and the interest thereon shall rank *pari passu* as a first charge on the undertaking and revenue of the company, the stock to be issued at such times, in such amounts, and on such terms and conditions as the board shall from time to time determine, for the purpose of redeeming by exchange or otherwise the outstanding debentures of the company, and any other purpose to which capital of the company may be lawfully applicable.

B. That the board be, and are hereby authorised to make such provision as they think fit for the registration and transfer of mortgage debenture stock, and for the delivery of certificates thereof, and for the issue of stock warrants to bearer transferable by delivery, and of interest coupons attached to such certificates and warrants or otherwise, and for the conversion of warrants to bearer into registered stock and of registered stock into warrants to bearer, and generally as to the form and incidents of all documents relating to the said stock, but so that no such provision be inconsistent with paragraph A of this resolution.

C. That the board be, and are hereby authorised from time to time to purchase in the market, and hold and deal with any amounts of such mortgage debenture stock for the purposes of any reserve fund or investment of the company, and, with the sanction of a general meeting, to apply other moneys of the company to the purchase in the market of any such stock for cancellation, and, with the like sanction, afterwards to re-issue mortgage debenture stock in lieu of all or any of the said stock so cancelled, provided always that the amount of mortgage debenture stock issued and outstanding shall never exceed the limit prescribed by paragraph A of this resolution.

The Chairman: You have heard the resolution read; I beg to move that the same be, and hereby is confirmed.

The Marquis of Tweeddale seconded the motion, which was put to the meeting and unanimously adopted.

The Chairman: That is all the business of the day, and we have now to act upon the resolution, and I hope that we shall be able to turn it to good account.

On the motion of Mr. Griffiths, seconded by Mr. Wells, a vote of thanks to the chairman was passed unanimously, to which the Chairman having responded, the proceedings terminated.

THE RAILWAY AND ELECTRIC APPLIANCES COMPANY (LIMITED).

On Friday, the 28th ultimo, under the presidency of Mr. Wm. Alex. Smith, of Glasgow, the statutory meeting of this company was held at Cannon Street Hotel.

The Secretary, Mr. Wm. Skinner, having read the notice convening the meeting,

The Chairman said: Gentlemen, I have to express the regrets of our noble chairman, the Duke of Manchester, who is unable to preside to-day owing to another very pressing engagement. He expressed his regret at the board meeting this morning, but hopes to have the pleasure of meeting you on a future occasion. Gentlemen, you are probably aware that this is what is called a statutory meeting, that it is a meeting which must be called within four months of the registration of the company, in conformity with the Act of Parliament. Of course, you are probably aware that although our company was registered four months ago we have not been in possession of our property until the last six or eight weeks, so that really the directors have only to report upon what has been done during a very limited period. I have to mention that two of our directors have lately visited Glasgow and inspected the works acquired by this company. You are aware that the works were situate in two different parts of Glasgow. The principal works which have become the property of this company were situated two miles to the south side of the city; the telephone apparatus and smaller electrical appliances manufactory was situate inside the city, thus necessitating very much waste of time in the transfer of goods from one of the works to another. The result of this is that it has been deemed expedient that the work should be concentrated under one roof, and thereby effect a very considerable saving. We have ample room for the extension of our works at Polmadie. Plans have been prepared and approved by the board whereby the object we now desire will have been obtained. In the meantime we have devoted our energies principally to consolidating the work we have in hand, getting up patterns for work we know we shall obtain, and generally organising the works, which will undoubtedly lead us to results which will enable us to have a profitable investment for our money. Some time ago we received authority from a commission of engineers appointed to inquire into electric lighting to send appliances to Chatham. This was done the week before last. Reports concerning the Maxim lamp are satisfactory to a degree. It is quite true that the Maxim lamp requires more power to drive it; but, on the other hand, it has advantages which will show it to be one of the best, if not the best incandescent lamp before the public. In the first place it is not so liable to break as other lamps. Two sessions ago the Glasgow Art Union asked us to fit up their galleries with electric lights, and after a series of experiments, which lasted over several months, we finally fixed upon the Maxim lamp as the best for the purpose; and the art galleries have been lighted by the Maxim lamp with perfect satisfaction to every one. During the last two sessions we have been able to replace 264 gas jets with 60 Maxim lamps, with the result that they not only got a better light, but a perfectly cool atmosphere even when the room was crowded, and the colours came out by electric light as they do by daylight. Now, the importance of that fact is almost sufficient, to those who have really thought the matter out, to convince any one that, be it this year or be it next year, electric lighting must take the place of gas. I care not how much you may improve the burners—and there have been vast strides made in that direction when they have been compelled to do it—but the fact remains that the light from the gas does change colours, and does prevent many people from distinguishing different shades. But this is not where it ends. Gas consumes the very life-giving property of the air—oxygen. When I tell you—which you would hardly believe—that the small gas burners consume as much oxygen as five men can consume, you can calculate how it vitiates the atmosphere when ten burners are going at a time in a drawing-room. My opinion is that the lamp we have acquired is one of the best, if not the best, yet brought before the public. I look forward to the time with a little patience and energy when there will be a vast field for the development of this incandescent light, especially amongst ships. I have the authority for saying this of Mr. Burns, one of the largest shipowners in the world, who says he does not expect to fit out another vessel without the electric light. This is only one of the many shipowners who have expressed their opinion. When we are in a position to conclude these orders, we may obtain a large share of the orders which Mr. Burns has to give. Another most valuable asset of our company is the Williams's Railway patents. They, to a certain extent, change the system of working railways in this country. They do away entirely with what is called the V crossings. They avoid all breaks in the main line of railway, and prevent many accidents, such as from the tire going the wrong side of the point. They enable you to put down a crossing at any part of the line you like without interfering with the main line; but that is not the only advantage they have. The present system of crossing takes a gang of men something like eight hours to fit in. That is, I mean, if any defect is discovered before an accident, and has to be adjusted, it takes that time to fit in. During that time the main line traffic is interrupted; whereas by the cross over system, which belongs to us, you can very easily fit up a crossing in half-an-hour without interfering with the main line. Why has not this system been adopted more largely? It was four or five years before Sir Henry Bessemer got steel rails adopted, and further, I may say, that the largest and most powerful railway has not yet adopted what has been practically admitted to be the only safe brake—the Westinghouse brake. The William's system is adopted on ten miles of line between Glasgow and Wemyss Bay. The Government inspector has inspected that line and reported very favourably on it. I have therefore, gentlemen, very little doubt in my own mind that with energy and pushing this matter, and by not being afraid to spend a certain sum of money in laying down experimental cross overs, and in demonstrating to the railway officials the advantage of these lines, we shall revolutionise the present system of railways. With these words I would ask you, gentlemen, to approve of the general action of the directors up tothis. If any gentleman has any question to ask I should be glad to answer him.

Mr. J. B. Hamilton (an original shareholder): In the prospectus the amount of capital asked for was £250,000, and I understand the amount of shares allotted is £100,000.

The Chairman: £180,000; about £170,000 was really all that was asked for.

Mr. Hamilton: The original was to be £250,000, of which the vendors were to have £95,000.

The Chairman: No, sir; £80,000.

Mr. Hamilton: The prospectus says £95,000.

The Chairman: Of which £80,000, at the option of this company, might be given in shares.

Mr. Hamilton: There is £195,000, including vendors' shares.

The Chairman: You are quite wrong, if you will excuse me saying so.

Mr. Hamilton: Well, then, call it £180,000 (laughter). The amount of profits in the first case would be 80-250th parts; if all the capital had been subscribed the vendors would get about one-third of the profits. Now that the capital is £180,000, you see that the proportion will be that the vendors will get 80-180th parts instead of 80-250th parts. Now, I would just suggest to the shareholders whether it is not a proper thing for us that the vendors should make an abatement to the extent of the difference. I say that the shareholders should consider whether they should not insist upon that, because on the face of the prospectus it was never contemplated that the vendors should get more than 95-250th parts. With the present limited capital they get much more (applause).

The Chairman: If any other gentleman has any question to ask, I may as well answer them all at once.

No further question being asked,

The Chairman said: I can only say I am very much indebted to Mr. Hamilton for having brought this matter up. Mr. Hamilton has clear ideas of what is right and wrong, and of what is fair and what is unfair. I have had the pleasure of knowing him for a number of years, and I can listen to any expression of his opinion with the utmost respect. I may tell Mr. Hamilton this, that his figures, although not exactly correct, his idea is correct. You must recollect this, Mr. Hamilton, that if the development of business requires it the directors have power to issue £500,000, which would only give the shareholders one-sixth instead of one-third part. The contract is made on a certain basis, that if we choose to issue our capital the vendors must be contented with one-sixth profits. Seeing that the capital is not fully subscribed, they are entitled to the proportion of £100,000. The new shares are just entitled to as large a proportion of the profits, the same as the vendors; there is no difference between them.

Mr. Hamilton: I have only suggested the thing to the meeting; if they think anything of it, they can think it over. I don't want to put it as a resolution.

The Chairman: No further question being asked, I think the business of the meeting is ended. I thank you for your attendance, and I hope we shall have a statement to put before you next time we meet that will please you.

After a vote of thanks to the chairman, moved by Mr. Cummings, the meeting separated.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).

The tenth ordinary general meeting of this company was held at the City Terminus Hotel, Cannon Street, on Friday, 28th ult., Mr. John Pender, M.P., chairman of the company, presiding.

Mr. J. W. Fuller, secretary, having read the notice convening the meeting and the report having been taken as read,

The Chairman said: Before making any general remarks I think it is necessary to give you a few figures as showing the working of our system during the past six months. Our revenue for the half year ending June 30th, after deducting out-payments, has amounted to £61,825 8s. 2d., and the working and other expenses, including interest on debentures and income tax for the same period, amounted to £24,979 3s. 2d., leaving a balance of £36,046 5s. 1d. as the net profit for the half-year, making with £4,623 0s. 8d. brought forward from the previous half-year a total of £40,669 5s. 9d., which has been appropriated as follows: Interim dividend of 5s. per share at 31st March last, £15,177 10s. 0d.; final dividend of 5s. per share at 30th June, now proposed, £15,177 10s. 6d.; carried to reserve fund, £9,531 9s. 1d.; written off for preliminary and arbitration expenses, £500; carried forward to next year, £282 16s. 8d.; total, £40,669 5s. 9d. Owing to the shilling tariff the revenue is much less than at the corresponding period of 1881 when the tariff was two shillings. It was hoped with the shilling rate adopted that the traffic would respond to the reduced rate. But ten months' trial of the rate has found that not to be the case. The American Telegraph Cable Company opened one cable at a tariff of two shillings on May 15th, and that tariff was in force on the other cables from May 22nd. A second cable was opened on the 30th ultimo. That company has actually participated in the joint traffic in respect of one cable from May 15th and two from June 30th, in proportion as agreed upon. The agreement entered into with the land company on the American side is working well, and the benefit of reduced expenses will be seen in our future half-yearly accounts.

Proceeding to the expenditure, it may be observed that while most of the items have either been reduced or remain practically the same as last year, there are one or two increased amounts. The salaries show an increase of £903. This is accounted for by the engagement of additional clerks in the December half year, and circumstances fully explained to the meeting on the 27th of February last. Comparing this item with the December accounts, however, it will be found to show a reduction of £291. For printing, stationery, and advertising there is an increase of £48 in London and £202 at stations, which has been caused by the increased consumption of message forms and other stationery and by advertising in regard to the two shilling rate. On the whole, however, the expenditure has been less than the corresponding period of 1881. During the financial year just ended we paid 5 per cent. to the shareholders, and we added £9,500 to the reserve fund. But it is only by the aid of two months of the two shilling tariff that this result has been obtained. Therefore you see, gentlemen, that while it was all our desire to maintain the shilling tariff, it would not pay. That is the real business expression—it would not pay. When I had last the pleasure of addressing you it was to ask your approval of the working arrangement just referred to, namely, with the American Telegraph and Cable Company and with the Western Union Telegraph Company. These arrangements are now in force, and, as you are aware, the joint companies are now working under the two shilling tariff. So that at the present moment the companies have no less than eight cables across the Atlantic, and when these are in good working order and duplexed they would for all practical purposes be equal to double the number, so that comparing the carrying power of the cables with the traffic there is a large surplus carrying power equal to any growth of traffic that is likely to occur for a considerable period. Now, gentlemen, if we felt that we could employ the surplus carrying power at the shilling rate, we should never have reverted to the two-shilling, and after experiment, which was fairly and honestly attempted, we were obliged to make up our minds to resort to the more paying tariff. Had we not done this I should not have had the pleasure of submitting to you the dividend which I now recommend. Do not misunderstand me. I believe there will be a considerable growth in submarine telegraphy, but its rise is slow compared with the rise it has made during the last twelve years. So far as figures prove anything, it would have taken us, under the shilling rate, at least four or five years before we could secure the return which we now do under the two shilling rate. That would have involved a loss of one and a half to two millions sterling. Looking to the fact that your dividends have never been large, and to the enormous benefit which these telegraphs confer upon the commercial as well as political and social life of the world, I think it would have been asking too much of the shareholders of this company to give up for a term of years the dividend to which they were fairly entitled. In previous addresses to you at these half-yearly meetings I have given you much information, and placed before you many figures on the subject of telegraphy. On the last occasion I proved to you by figures that the shilling tariff was not sufficiently remunerative, even upon the reduced prices which telegraph property can be constructed to-day, because the feeling is that our stocks are watered; but if you take the cables now laid and working well, they could not be replaced by the amount of capital represented by the market value of the respective companies, not to speak of the large reserves held by some of them, so that that puts the question of working entirely aside. The value of a thing is what it will bring in the market, and the price in the market to-day with the shilling tariff would never give anything like the return upon the investment; but, notwithstanding all this, it must be a great field for enterprise, and the more uncertain it seems to me, the more mysterious, the more indefinite, and the more risky the operations are, they seem to be just the very thing which attract company promoters, and command more attention than those enterprises which are sound and more easily understood. For instance, we are now threatened with two additional cable companies in the Atlantic: one, the European and Canadian Company—I think it destroys itself by the fallacy of its own figures, and the letter addressed to the *Times* by Mr. Weaver, of the Anglo-American Company, proves this; and I think there is no harm in my calling public attention and the shareholders to the subject of their position. Their position is this: assuming that the two cables could obtain a full proportion, or 1-5th of the total of the traffic, assuming a traffic of 16 million words per annum, then they would have to carry 3,200,000, which, at 9d. per word, would yield £120,000, an amount which would fall far short of the remuneration for working expenses, reserve fund, and paids-out. If we take these figures, putting in the working expenses and paids-out at £48,000, and the renewal fund at £45,000—which, by the way, is not provided for in the prospectus set forth—there would be a loss of £5,000. It is necessary to draw attention to the statement that in this sum of £80,000 the paids-out and the amount of money paid away for land-lines transmission in the United States, Canada, and England, are calculated; reckoning the sum paid out at only 1s. 2d. a word, would amount to £20,000; but reckoning it at 3d. a word and this is what I should think could be the lowest average, it would absorb £4,000. There is no doubt as to their working resulting in a loss instead of profit at the price they profess to work it. There is no special provision made for cost of repair and interruption of cables, which is certain to occur. We know what these have cost this company, and what they cost all other similar enterprises; such repairs cost this company £90,000 during first year of its existence for repairing one cable only, and this is an item that this new company has entirely left out of their calculations. With regard to the proposed adoption of the mutual principle, let me suggest that it is possible that this system may resolve itself into a mutual subscription system, to make up the loss which would certainly fall on those who enter into mutual obligation and enterprise. Rumours of telegraph companies seem cropping up every day. Speculators, no doubt, have a great deal to do and say in these reports, because they are a very good handle for depressing and influencing the stock market. But for those who have placed their money in them for investment I would say, "Do not be frightened or run away at the reports circulated for interested purposes. If it does depress the stock, the low price will eventually strengthen those companies by bringing in a large number of bona fide investors, who will ultimately reap the advantage." It is my duty on an occasion like this to warn our own shareholders not to be alarmed, to rest satisfied that those who are watching over their affairs will take good care they are fully looked after

and shareholders will be well informed and advised whenever occasion renders it necessary. There is no question at all in my mind that the combination threatened by the Eastern Cable Companies and the Western Union Telegraph system of America will carry under any circumstances the bulk of the traffic, for the best of all reasons that they will be able, with an improved system at their command, to deal with their work more expeditiously than any new system could possibly do, and speedy telegraphy means time to the commercial man. Now, gentlemen, I hope you will excuse my making these remarks to you, because the submarine system is now become so very important that it has become for the world a necessity, and it would be a grave misfortune if for speculative purposes the property of a system so beneficial to the world should be discredited by men whose only object is to get a little money out of the contracts in the first instance. I trust telegraphy has a sounder basis, and those who have ventured into this particular class of property will have the satisfaction of knowing that it is now recognised property, and that the amount of good if not so large to themselves is likely to be in time so developed and matured as to make it a sound investment for them, and for the world it is really indispensable. With these remarks I beg to move that the report of the directors, dated July 19th, 1882, together with the statement of accounts to June 30th, be, and the same hereby is, adopted, and a final dividend of 5s. per share free of income-tax be declared, making with interim dividends a total dividend of 5 per cent. for the year ending June 30th, 1882.

Mr. Ford seconded the motion.

Mr. Jackson said that while he was glad that the company was so flourishing, and while cordially endorsing the chairman's remarks as to the value and efficiency of the telegraphic communication through the old companies, he thought it would be well in regard to the accounts to remove from the capital account the small balance in regard to the preliminary expenses. It was small and they had reduced it from time to time, but he thought it would be satisfactory to see it removed from the accounts altogether.

Mr. Newton said that since he had come into the room he had had a letter handed to him in regard to the new scheme circulated in the newspapers; he referred to Mr. Weaver's letter. He thought it should be circulated amongst all the shareholders. He believed that the scheme was simply to put money into the pockets of a gang of schemers, and it was no use mincing the matters. It was simply a combination of promoters of companies, and he was sure that existing shareholders would never benefit by the multiplication of telegraph companies. He was certain that they would have to battle with this difficulty sooner or later, and it was better, he thought, to take vigorous measures at once.

The Chairman: With regard to Mr. Jackson's remark he is perfectly right. But we have been writing off every year, and it was even discussed as to whether we might not write off a large sum at this time. But as we were placing a smaller sum to the reserve fund, and this last half-year embraced a considerable proportion of the shilling tariff, we thought it better not to be too severe on the shareholders, as we were desirous of maintaining the average interest at 5 per cent. As we have come back to the two shilling tariff we shall able, I think, be to put aside a larger sum than this shortly. As regards Mr. Newton's remarks, there is no doubt that Mr. Weaver's letter is one which must commend itself to all thoughtful men about this new company. As far as I can hear I think it has pretty well destroyed it; but still more destructive to their interests, I think, is their reply to Mr. Weaver. The weakness of the secretary's reply is so plain that any one who runs may read; and as to fighting them, they say, "Burnt bairns dread the fire." I am afraid the only way in which we can get rid of it is simply by people losing a little money by it, because it is as true as possible the companies which are now existing and which have got a certain amount of goodwill and position unfortunately stand at the present moment at 50 per cent. discount, and a new company cannot expect their stock to stand higher. I cannot conceive how they can get 20s. for an article not one half—not one fourth—as valuable as an article which can be bought in the market for 10s.; but they say that it takes ten years to bring up a crop of fools, and I think we are in that position now, and, so far as I can learn, there is very little chance of this new company ever getting beyond the paper of the prospectus which has been issued.

The resolution was then put to the meeting, and carried unanimously.

The Chairman then moved that Admiral Mayne be re-elected a director of the company.

Mr. Quilter seconded the motion, which was also carried unanimously.

The Chairman next moved that Mr. Charles Meara be likewise re-elected.

The motion was seconded by Mr. Ford, and carried.

Mr. Jackson moved that Mr. John G. Griffith and Mr. Joseph Sawyer, the retiring auditors, be re-elected.

Mr. Newton seconded the motion, which was likewise carried unanimously.

Mr. Griffiths and Mr. Sawyer briefly returned thanks for the honour done them.

Mr. Jackson said that it was usual, and he thought upon this occasion certainly more desirable than usual, after the trouble and time which the chairman had taken to get at the facts so lucidly laid before them, to propose a vote of thanks to the chairman and board of directors, and he had therefore much pleasure in doing so.

Mr. Hinton seconded the motion, which was put to the meeting and carried unanimously.

The Chairman in responding said: On behalf of my colleagues and myself I beg to thank you. I can only assure you that this is an enterprise—submarine telegraphy—that seems to be exceedingly attractive, and just as it is attractive it entails upon us greater trouble and greater responsibility, but it is a responsibility that we feel; and we are anxious to secure even a higher object than simply good dividends—that is, to secure for the public as well as the shareholders a thoroughly efficient and beneficial system of telegraphy. That object we have in view, and I think we have fairly proved it since we took up the management of this cable. We have fairly proved that such a system can be conducted in a way that will give satisfaction both to the shareholders and the general public. As you know, it is not a large dividend which we are paying, but we have been able to continue that dividend through very trying and troublesome times, and I am still hopeful that if we continue free from competition for a little time we should even add something to it. In the meantime we must husband our resources and take very great care as far as attention and watching closely all proceedings that appear to us to concern your interests. I should add that we have the most hearty co-operation from our friend Mr. Weaver, who with his wide experience has rendered very valuable and important aid to us. I think when such experience is brought to bear—when I compare such experience as this with the prospectus which has been presented to the public—I can only say that if there is any practical knowledge that will lead our enterprises to a successful issue, I think I can say that we are able to avail ourselves of it (hear, hear).

The proceedings then terminated.

THE SUBMARINE TELEGRAPH COMPANY.

The report presented at the meeting of the shareholders of this company for the six months ending June 30th, 1882, shows a balance of profit in favour of this company of £38,516 4s. 6d., which enabled the directors, after adding 10 per cent. of the gross receipts to the reserve fund, to recommend a dividend at the rate of 19 per cent. per annum, and carry over to the next account the sum of £123 16s. 9d.

The cost of repairs to cables during the half-year have been less than in the corresponding period of the year 1881, by the sum of £1,338 12s. 2d. All the cables belonging to and worked by the company are at the present moment in good order.

In accordance with the resolution passed at the meeting of the proprietors in February last, the directors have contributed on behalf of this company and the Société Carmichael et Cie., the sum of £200 to the fund being raised for the benefit of Mr. Jacob Brett, and charged this sum and a further amount of £740, which has been granted to the widows of three clerks, lately deceased, against the revenue of the half-year.

On Tuesday the half-yearly ordinary meeting of the abovenamed company was held at the offices of the company, 2, Throgmorton Avenue, Sir James Carmichael, Bart. (chairman of the company), presiding.

Mr. S. M. Clare, secretary, having read the notice convening the meeting,

The Chairman said: Now, gentlemen, the report and accounts having been circulated for some days, I suppose you will take them as read ("Take them as read"). I have often had the pleasure of moving the adoption of the report and accounts of this company, but I do not know that I ever did so with so great a feeling of difficulty in having nothing to say to you. I have not the smallest peg on which to hang a speech. Therefore my remarks will be very few and very concise. In looking over the report you will doubtless have observed that the repairs to our cables have been lighter during the last half-year than usual. In fact, we have been very fortunate in regard to our repairs to cables. By looking at the item of salaries you will see that there is an increase of £1,690 over the corresponding half-year in 1881. Now, this chiefly arises from the very large number of messages we have carried during that period, which amounts to 100,000 in excess of the number transmitted in the corresponding period of last year. This increase has necessitated our opening and establishing eight additional circuits with the Continent, and in consequence we have had to employ fourteen additional clerks. That will pretty well account for the increase you see in the amount of salaries. I think it will be pleasing to you all to know that on the 19th of June we transmitted the largest number of messages ever sent over our wires in one day; 10,867 were sent; and during that week 58,000 telegrams, containing 751,059 words were transmitted—the best week we have had in the history of the company. I congratulate you very much upon it, and I trust business will go on as during the past half-year. I am sure you will all lament the death of our old and valued colleague, Mr. Samuel Gurney, who was, with the exception of myself, the oldest director of this company, having been elected a director in 1858. I have now really nothing else to detain you for; I have told you a short story, and one which I hope you are pleased with. I beg now to move the adoption of the report and accounts.

Mr. Forde seconded the motion and said: I congratulate you on having all your cables in good order, and I hope they will be continued so.

The Chairman then put the motion, which was carried unanimously.

The Chairman then said: I beg to move that in accordance with the recommendation of the court of directors that a dividend at the rate of 19 per cent. per annum, less income-tax on capital, be declared and paid on and after September 1st next.

Mr. C. Smith seconded.

This resolution was also put and carried unanimously.

Mr. Forde then moved that Sir J. R. Carmichael, Bart., the Hon. Ashley Ponsonby, the two directors retiring by rotation, according to the deed of settlement, be re-elected. He need add no words of commendation.

The motion, having been seconded by Mr. Jowne was carried.

Mr. C. Smith proposed that the retiring auditors, Mr. Geo. Copeland-Capper, Mr. W. R. Cole, and Alderman Sir Thos. Dakin be re-elected. He remarked that the present state of the accounts testified so very much in their favour that there was no need to say anything further.

Mr. Harvie having seconded this motion, it was also carried unanimously.

The Chairman then proposed the election of Henry R. Brand, Esq., M.P., as a director, in the room of Samuel Gurney, Esq., deceased.

The motion was seconded by Mr. G. C. Capper, and carried.

Mr. Forde proposed a vote of thanks to the chairman and the directors, congratulating them on being able to put before the meeting such a satisfactory report on that occasion.

This was seconded by Mr. Jowne, and the chairman having very briefly replied, the proceedings terminated.

UNITED TELEPHONE COMPANY (LIMITED).

The report states as follows: A reference to the capital account will show that up to 30th April, 1882, the sum of £55,966 13s. 8d. has been expended upon the works in connection with the London and Provincial Exchanges and the Stock of Instruments, being £21,739 9s. more than the outlay shown in the last balance sheet. The revenue account shows that the receipts of the company from all sources properly attributable to the year have been £42,624 15s. 3d., as against £20,644 10s. 6d. in the preceding year, or an increase of £21,980 4s. 9d. The working expenses of the year have been £21,050 4s. 3d., as againt £20,273 12s. 11d. for the preceding year, or an increase of £776 11s. 4d. The balance of net revenue is £21,945 8s. 7d., and the directors recommend the distribution of a dividend of 5 per cent. for the year, leaving a balance of £1,945 8s. 7d. to be carried forward. Subject to the approval of the proprietors, it is intended that this dividend shall be payable on the 2nd August. The above figures of themselves illustrate the progress of the business. It will be observed that whilst the working expenses have but slightly increased, the receipts have more than doubled; and the board feel that, considering the short time the company has been in existence and the many difficulties that have had to be overcome in creating and meeting a new public want, the result may be regarded as very satisfactory. As an evidence of the progress of the business it may be stated, that the numbers of subscribers to the London exchanges of the company has increased from 914 on the 30th April, 1881, to 1,673 on the 30th April, 1882. Since that date a large additional number (which is growing from day to day), have been secured. The private line business has increased from 186 lines to 366 during the year. Considering that the public are only beginning to realise the great convenience and saving of time and expense consequent upon the use of the Telephonic Exchange system, and having regard to the practical difficulty attending the erection of the necessary machinery for the efficient performance of the service, the board hope that these results will be appreciated by the proprietors. The board are happy to be able to say that they are working in harmony with the Post-office, and they feel assured that as every day must manifest, more and more clearly, how admirable and indispensable an adjunct to the work of the Post-office the telephone is, the relations with that Department will extend and become closer. The recent declaration of the Postmaster-General that the Post-office do not favour a monopoly of telephonic communication either for themselves or others is so far satisfactory, that it will enable the Department to grant the company licences for many important towns and districts from which they have hitherto been excluded pending that decision. As to the policy itself it will no doubt satisfy an abstract principle, but if widely applied it can only lead to embarrassment and serious limitation in the use and value of telephonic exchanges, which depend upon the possibility of placing the whole of the subscribers in any town or district in communication with each other. This great object will be seriously impeded by the multiplication of competitive companies (assuming any of them to possess the means of competition without infringing the rights of this company), each having a number of subscribers cut off from the subscribers of the other. The board have from time to time during the year notified to the proprietors the result of the several proceedings forced upon them for the protection of their rights. It is, therefore, not necessary to say more on the subject, than that in the Scotch case the company's position as exclusive owners of all the essential patents was explicitly and fully confirmed; whilst in the English case the validity of the Bell patents was entirely established, and the validity of the other patents practically so, the judgment being entirely in favour of the company as regards the transmitters, and only failing by reason of a purely technical point not affecting the real question. The board have taken all necessary measures both by appeal and disclaimer to remedy the failure, and they are advised that their claim to possess the only possible, as well as the best telephonic instrument, must shortly be finally established. The board, following the policy already adcpted of making over to persons locally interested the management of the telephone business within the limits of particular districts, conditionally upon the formation of district companies affiliated to the parent company, have to ask the shareholders to confirm the agreements in relation to the "Telephone Company of Ireland, Limited," and the "Western Counties and South Wales Telephone Company, Limited." The general basis of the agreements under which the business is transferred is the repayment to the United Company of all sums expended by them in the districts up to the date of the transfer of the business, one-half of the ordinary capital of the district companies, and the further payment of annual royalties upon the telephones used. Negotiations are also pending for the creation of other subsidiary district companies.

On Tuesday, at noon, the second annual ordinary general meeting of the abovenamed company was held at Cannon Street Hotel, James Brand, Esq. (chairman of the company), presiding.

The notice convening the meeting having been read by the Secretary, Mr. Blaikie,

The Chairman said: Gentlemen, we have first to submit to you the report and accounts for the year ending 30th April, 1882. You have all read them and looked into the accounts, I have no doubt, and therefore I suppose you will take them as read; and it will be for me now to make a few remarks, and I will make them as few as possible, on the subject of the report and accounts. As I am not very good at making speeches I have written out what I have to say, which will occupy your time less than if I were to fumble away at a speech (laughter). As to the report and accounts I think we have made them so clear that they will require very little explanation from me, and will leave not a great deal for me to say; but I think I may fairly congratulate you on the progress we have made, and considering the large additions made to our system and the amount of work we have done, I think our capital expenditure has not been excessive. We may, at any rate, congratulate ourselves that the work for which you have paid has been good work, for notwithstanding the sinister prognostications which, I dare say all of you remember although a year and a half ago, when we were in much trouble, were made by some of those who were connected with us in the early part of our undertaking, who said that not only was our work bad, but that it would be a source of fatal mischief to the populace, and that your chairman and directors would in consequence run the risk of indictment for manslaughter. I am glad to tell you we have not had one single accident with our wires, and our works have stood the test of very heavy wind storms, perhaps the heaviest during the lifetime of any of us. That is a fair subject of congratulation. You will notice that our revenue has increased up to April 30th by nearly double; since then we have had a further very large increase of fresh subscribers coming in very fast. Our working expenses, no doubt, are heavy. They show a very small increase on last year, and notwithstanding the large increase of business our indefatigable managing director, Mr. Morgan, uses every effort to keep them down; and no doubt as we get more and more knowledge of the working of our peculiar business, and avail ourselves, as we do, of every new invention that we find out to be an improvement, we shall succeed in reducing our expenditure under this head, and we fully believe that its proportion to our income will become less and less every year. As to our modest dividend, I can say we have earned it. We could, of course, with your permission, have followed the same course we did last year and realised a part of our shares in one of our subsidiary comp anies, so as to make a good division in the shape of bonus. But we have considered the course we are pursuing is the best for your interests; we divide what we have fairly earned, and for the present are leaving our shares in our subsidiary companies to stand as a means of helping to earn our dividend and as a substantial reserve fund in addition to the large sum we wrote off last year against renewals, depreciation of plant, and all the troubles our business is heir to. I come now to our relations with the Post-office, which is the most important part of our business, and to the satisfactory carrying out of it. I think our report is pretty clear on that point. We are using every effort to satisfy the Postmaster-General, as well as the public, that we are able and willing to perform the services and duties we have undertaken. I believe we have given him, so far, such satisfaction that he sees no need to exercise the right reserved to him of stepping in, if necessary, and doing our work himself. We intend to make our service much more perfect. Perhaps some of you will say there is much need for that; but if you knew the difficulties with which we have to contend, you would be very lenient, I am sure. I may say on this point that if you have any complaints to make, if you will write to Mr. Morgan, our managing director, or to me, I will take the trouble to attend to it personally. We are now endeavouring to make great extensions in our work, and we hope very soon to extend the blessings of the telephone to various seaside places. I do hope that soon almost every town in Britain will be in communication with London, and I do not think it will be very long. We are getting on very well with the subscribers in Britain, and I have no doubt that business men will soon be enabled to get holidays by using the telephone, and so communicating with London. But all this involves enormous time and labour, especially in the matter of wayleaves—and that is a very difficult point—a point which, as we have to go long distances and use railways, we could scarcely overcome except with the cordial co-operation of the postal authorities. You will doubtless have seen Mr. Fawcett's statement that he did not consider he could continue to grant anything in the shape of a monoply to any one telephone company. The monoply we did enjoy, if it could be called a monoply, was one of the very mildest kind, and, as I before stated, the Postmaster-General reserved to himself the right of taking our business over and doing our work himself, if we could not perform it, and I think it was more of a matter of carrying out his free trade principles, or something of that kind, that induced him to alter his previous decision, which I venture to say was the just decision, that this company, being the progenitor of the telephone work, and because the telephone business is a very difficult one to carry out, I think he made a just decision in confirming the work to be done by companies. However, as to this matter, one company alone has been able to carry out satisfactory telephone work. I am bound to say, because I believe it to be entirely true, that it cannot be satisfactorily carried out in any one town or district by more than one company or system, for independently of the trouble and difficulty created by rival candidates for subscribers and way-leaves, the benefit of the telephone would be partially destroyed, by the fact that the subscribers to one system would be cut off from communication with the subscribers to another. We have taken every pains and gone to considerable expense to ascertain the facts, and we find that since the telephone was invented in America and Europe, wherever it has been attempted to introduce two or more systems in one place, dire confusion results, and in the end, parties have been forced, either of their own accord or by the action of Government, to fuse their systems and use identical instruments. However, it has been thought fit to announce that a licence will be given to certain persons if they show themselves worthy of it and responsible; and if any persons do obtain a licence, they will first have to obtain proper instruments to carry out the business, which I think at this moment is rather a doubtful enterprise on their part. Then they will have to get subscribers; and then will commence all the real troubles of their undertaking; troubles we have undergone and are undergoing, but have successfully got over

to a very great extent. All I can say is we are not afraid of competition. We shall continue as we have done all along, honestly to develop our very great and interesting enterprise. As to our patents, which one way and another have cost us much money and anxiety and law, we have at last, I hope and think, put them on a satisfactory basis. We have from time to time fully informed you by letter of our progress in the law-suits that have been forced upon us. In Scotland we have been entirely successful, and Lord M'Laren upheld the validity of our patents to the fullest extent. The appeals which have been lodged against his decision have been withdrawn. In this country the technical objections which to Mr. Justice Fry seemed fatal to our Edison patent for a short time, were, you will be glad to hear, overcome by disclaimer on Saturday last (hear, hear). I will read you on this subject what Messrs. Waterhouse and Winterbotham say. This letter was written last night:—

"Dear Sir,—You will like to be able to report to the shareholders at the annual meeting to-morrow the present position of matters with regard to the company's patents. We may assume that they are acquainted with the contents of the circular letter of the 24th of May last in which the successful issue of the proceedings in Scotland were reported, and also the result of the more recent litigation in this country before Mr. Justice Fry, resulting in a judgment for the company on the Bell patent, but in an adverse decision on the Edison patent upon a technical question relating to the phonograph. In substance his Lordship's decision amounted to this, that Mr. Edison's claim for what is known as the carbon transmitter was a good claim and covered the instrument used by the defendants, but that Mr. Edison having included in the same patent a claim for the phonograph (which claim could not be sustained in consequence of an insufficient description of that invention in the provisional specification) the whole patent was vitiated. As the result of a very careful consideration of the question by counsel immediately after the decision of Mr. Justice Fry, it was thought well to apply at once for leave to disclaim the phonograph without waiting for the decision of the Court of Appeal on the question whether Mr. Justice Fry was right in his decision on this point or no. The case could not have been brought before the Court of Appeal until the end of the year, and although the counsel advised that the appeal would probably result in the company's favour, this was necessarily only an opinion, while a disclaimer would be decided more promptly and if obtained would dispose once and for all of the objection. The necessary application for a disclaimer was accordingly made, and we are glad to be able to report that the Attorney-General, on Saturday last, after carefully considering the whole case, granted the leave asked, and the necessary disclaimer will be forthwith filed. The only objection upon which the defendants were successful being thus disposed of Mr. Justice Fry's decision upon the patent as it now stands is on every point in favour of the company. We think therefore that you may now congratulate the company upon having two patents which have stood the most searching and hostile criticism which the ingenuity of the legal and scientific mind can bring to bear upon them, and although it is of course possible that the great value attaching to these patents may induce some adventurous persons to carry the litigation to a higher court (if they can induce the public to find the money for the purpose) we have every confidence that they will fail in reversing the decisions which have already been given. We are, dear Sir, yours faithfully,

"WATERHOUSE & WINTERBOTHAM."

I think that announcement is a very gratifying thing to all of us. To show you a little more how the decision will act, we telephoned Messrs. Waterhouse and Winterbotham, and they say that some of our opponents have been attempting to get up a company to do this business, and they said that they had Hunnings' transmitter to use in conducting the business. This transmitter we were advised of as being a childish infringement upon our Edison patent. When we lost the action to a certain extent, of course this Hunnings' transmitter was open to the public for a time, and these gentlemen immediately seized the opportunity to manufacture an enormous quantity of them, so that whether he won or lost eventually they would be able with the proceeds of the articles they took from us,—to use a mild term,—to enter into competition with us. But, however they may have benefited, our disclaimer of Saturday protects us. As to the *bona fides* of the contract, this will be referred to the Attorney-General, and, no doubt, upon such a question he will give a fair decision, as satisfactory as possible to both parties. I do not know whether you expect me to say a word as to what is the value of our business, and so forth. Of course I have no wish to induce any one to invest in telephone securities, but to our shareholders I would say, under no circumstances should you be in a hurry to part with your property, and although we have only as yet been able to pay a small dividend, you must not forget that our enterprise still is a very new one. We have overcome Government difficulties, and I am certain that we are on the eve of overcoming much greater difficulties. We may yet meet with, of course, opposition and trouble of every kind. In our progress through life we are entitled to expect that, but I do not waver from the constant belief I have always entertained that the United Telephone Company will triumph. As it has hitherto done over the obstacles in the past, so we shall triumph over the obstacles in the future; and there is no kind of doubt that against any kind of opposition or competition from any and every source we shall continue to carry on business, as we have done, with our utmost efforts and our greatest anxiety for the interests of the shareholders that have been confided to us, and I am certain we shall prosper and triumph and prevail in the end. I do not think that I have anything more to say, but I have to move that the report be taken as read and received and adopted. Of course, if any gentleman wants to ask any questions at all about anything connected with the business, all of us shall be only too happy to afford the fullest information in our power.

Joseph Forbes, Esq., seconded the motion.

Mr. Galsworthy said that the report must appear almost too satisfactory. The revenue for the year had been £42,624, against £20,644 for the previous year, or more than double; whereas the expenses, although heavy, had only increased by £766. If they went on like that they ought to have a very good dividend next year. The number of subscribers had increased from 914 to 1,673, which seemed a capital index of prosperity, as it meant the doubling of the business in twelve months. It appeared too that it was a practical impossibility for them to have any competition. Just let them imagine a dozen telephone companies in London! If they were brought out he had no doubt that the public would take shares; but what a state of confusion would result if there were a dozen sets of subscribers none of whom were able to communicate with any of the others. He believed entirely in the policy which the directors were carrying out—that of keeping the dividend down to a moderate sum. Those of them who held shares as an investment did not want to run the shares up in the market; they hoped, indeed, for a larger dividend next year; but their first business was to put the company on a permanent and stable basis as a business concern.

A shareholder asked what was the increase of subscribers since the date to which the report was made up?

The Chairman said that he was glad to say that since April 30th, to which date the report supplied the figures, the number of subscribers had increased from 1,673 to 1,924 (hear, hear), and they were running their wires twice as quick as they used to do. Mr. Morgan being at it all day long had found out a way of working that was far better than the old one. With regard to the increase of expenditure over last year he might say that they had satisfied themselves that their income would steadily increase, and, with their management, the expenditure would not, he thought, show any very large increase. He would ask Mr. Morgan to read a summary of the work they did during the past three months for the satisfaction of the shareholders.

Mr. Morgan read a tabular statement which showed the orders received in the first three months of 1880 to have been 90; in 1881, 238, and in 1882, 319. Lines opened:—In first three months of 1880, 75; in 1881, 196; in 1882, 395. Average calls per subscriber:—In 1880, 4·28; in 1881, 5·16; in 1882, 6·88. Total calls during the year 1880, 943,831; in 1881, 2,313,000; at the present time close upon 4,000,000. Subscribers on 30th April, 1881, 914; on 30th April, 1882, 1,673; present time, 1,924. The rate of opening the wires had averaged 100 a month since last October. During June last 130 wires were opened. The number of exchanges in 1880 was 7; four more were opened in 1881, three more in 1882, and during the last three months an additional exchange had been opened at Smithfield, making a total number of 15.

The Chairman: The first resolution is that the report of the directors for the year ending April 30th, 1882, be taken as read, received, and adopted.

James Staats Forbes, Esq., seconded the motion, which was carried unanimously.

The Chairman: The second resolution is that a dividend of 5 per cent., less income-tax, on the paid-up capital for the year ending April 30th last, be now declared.

Mr. Forbes seconded the motion.

Mr. Galsworthy said that it was very inconvenient to pay income-tax on the dividend, and he thought it would be better to declare it free of income-tax.

The Chairman said that they had taken their usual course, but they would remember the suggestion next year.

The resolution was then put to the meeting and carried unanimously.

The Chairman: Resolution 3 is that Messrs. John W. Batten, Joseph B. Morgan, and Col. Gourand, who retire from the Board by rotation, be re-elected.

Mr. Forbes seconded the motion, but suggested that the names should be put to the meeting individually.

This was accordingly done, and the three gentlemen were unanimously re-elected.

Mr. Garrett asked if there was any objection to having half-yearly meetings?

The Chairman: Personally I have the very greatest objection to half-yearly meetings, because I have to make speeches, and that is a dreadful task (laughter). Don't you think a circular every half year would answer the purpose? We will consider it, of course. If the question is one of having an interim dividend it may be a course to be adopted.

Mr. Agnew, M.P., then moved that the auditors, Messrs. Quilter, Ball & Co., and Messrs. Price, Waterhouse & Co., be re-elected at a remuneration of fifty guineas each per annum.

Mr. Galsworthy seconded the motion.

Mr. Garrett asked if it was necessary to have two professional auditors in a company of this kind?

The Chairman said that that was a matter which rested entirely with the shareholders.

Mr. Garrett said that it was solely a question of keeping the expenses down.

Mr. Agnew thought that if they employed one auditor only they would probably have to pay him 100 guineas; the existence of two auditors was an additional security.

The resolution was then put to the meeting and carried unanimously.

The Chairman: The next resolution is that this meeting confirms (subject to such modifications as the directors may think fit to make) the agreements with Mr. Arthur Dudgeon and with Mr. George Hunter Robertson, dated respectively the 22nd March, 1882, and the 31st March, 1882, for granting in the first case to a company formed under the name of "The Telephone Company of Ireland (Limited)," and in the second case to a company intended to be formed under the name of "The Western Counties and South Wales Telephone Company, Limited," exclusive licences for the use of the company's patents in certain districts, partly in consideration of full-

paid-up shares in such respective companies and partly in consideration of royalties, and in connection with such licences to sell for fully paid shares and cash any business now carried on by the company within the districts comprised in such licences respectively and any property used in such business. These are two more companies formed upon the basis of the Lancashire Telephone Company and the National Telephone Company, which are going on, I think I may say, in a fairly satisfactory way, and which I hope will be of even more value to us than they are now. The capital of the Irish Company is £200,000, £25,000 being in preference shares of £10 each, and £175,000 in ordinary shares of £1 each, of which the United Telephone Company receives £87,500 in shares. The amount to be repaid to us in cash for the expenditure already incurred in Dublin and elsewhere in forming the nucleus of this business, now selling, is about £5,500. As to the Western Counties Company we propose a capital of £275,000, of which £25,000 is in preference shares of £5 each, and £250,000 in ordinary shares of £1 each, of which the United Company receives £125,000, and the amount to be repaid in cash for the expenditure is about £6,000. I think it is necessary for you to pass these resolutions in order to enable us to get these companies floated.

Mr. Galsworthy asked if the Western Counties Company was yet founded?

The Chairman said that it was as good as founded. But for some little hitch it would have been completed before this time.

A shareholder would like to ask a question, but would not press it if it was in any way inconvenient to the board to answer it. What hold had they got in the provinces at present, how many subscribers had they there, what towns they served, and whether they were sufficiently strong in those towns to hold their own against any rivals, as he understood they could do in London?

The Chairman said he could not go into these details, because they did not properly belong to them. The property in the provinces belonged to the Lancashire and Cheshire Company, the National Company, and the Northern Company. He thought they were fairly strong in all the towns they had the licence for. They had not yet succeeded in getting licences for all the places they should like, but the new decision of the Postmaster-General would enable them to have licences for every place not licenced. The Chairman of the National Company, who was present, could doubtless give the fullest information on the subject.

Mr. Forbes then seconded the resolution.

In reply to a question by Mr. Galsworthy as to the disposal of the South Western Counties Company's stock, the Chairman said that they got one-half (£125,000) of the issue: the local company distributed the other half to people useful in forming the company, to men who were owners of collieries and tin works and so forth, who would be likely to employ the telephone.

Mr. Agnew, M.P., said that the chairman had stated that he had not the gift of making a speech. He had heard from time to time oratorical speeches from the chair, yet he was glad to say that he had never heard a better speech than that read at this meeting. The chairman and his colleagues had manned the ship and piloted it through the troubled waters, and he thought the shareholders must agree with him that they were somewhere near the promised land at last. He was sure that the chairman and the other members of the board had given to this enterprise time and energy to the disadvantage, he believed, in many cases of their own personal affairs, and he thought that the shareholders were greatly indebted to them for the patient labour and care which they had devoted to the interests of the company. He begged to propose that their thanks be given to the chairman and the members of the board for their attention to the shareholders' interests, and for the position which their report upon this occasion showed that the company occupied.

Mr. Forbes would second that part of Mr. Agnew's motion referring to the chairman. He did that as a shareholder, first, to be within his right, and in the second place, because from his association with the chairman from the very inception of that business he was perhaps a better judge, and one more entitled from personal knowledge of his qualities than perhaps any outsider living. Their chairman had that characteristic of all strong and big men—exceeding modesty (laughter). He stated that he could not make a speech, yet they saw that he could. He could say of him that a more earnest, courageous, honourable man did not exist in the City of London; and he had besides that great quality without which no great enterprise was ever pulled through, however ably it might be conceived—pluck and entire faith in what he was about. He had no hesitation in saying that but for the possession by him of these qualities in more than an ordinary degree, this company would not have been in so good a position as it was in to-day. If it had lived through early divisions and great discouragements, that was owing a great deal more than he could describe to the qualities of their excellent chairman. Therefore he felt privileged in being allowed, as far as the chairman was concerned, to second the motion before the meeting.

Mr. Galsworthy said that nothing was more difficult to manage than a telephone company. Directors were overwhelmed with details and practical difficulties of all kinds, therefore all the more credit was due to the chairman of the board for the good position which the company now occupied. He was very glad indeed to see that their friend Mr. Batten was re-elected, because there was enough law in his head to pull them right through any of their difficulties. Whether they looked at the board as a whole or as individuals they must feel great confidence in their skill and ability.

A shareholder asked under what item the law expenses for the year were included.

The Chairman said that the legal expenses were included under two heads in the accounts—£4,702, and the remainder shown in the balance sheet as £350. There were no other legal expenses save those connected with defending their patents.

Mr. Joseph Dodds, M.P., said that he did not understand that the resolution [illegible] nded except in so far as the chairman was personally concerned. He had much pleasure in supplying that defect before putting the resolution to the meeting. With regard to the speech of the chairman, he could say, like his friend near him, that though he had attended a great many meetings of shareholders and public meetings of various kinds, he never, in the whole course of his experience, heard a more comprehensive, clear, business-like statement than that put before them by the chairman. He had much pleasure in seconding the motion, and a vote of thanks to the directors generally.

The motion was then put to the meeting and carried unanimously.

The Chairman said that, on behalf of his colleagues and himself, he had to thank them very much. They could certainly take to themselves the praise that they had endeavoured to do their best, and he could assure the meeting that they would endeavour to do their best for the future. They wished to do all that was possible, and if they had failed in any way it was because they had not the ability, not because they had not the will (hear, hear).

The proceedings then terminated.

Settling Day and Quotation.—For these application has been made to the Stock Exchange Committee, in the case of the South African Brush Electric Light and Power Company (Limited). Shares.

Quotation has been granted to the Brush Electric Light and Power Company of Scotland (Limited).

W. T. Henley's Electric Light and Power Company.—A call of 10s. became due on the shares of this company on the 1st. inst.

TRAFFIC RECEIPTS.

Western and Brazilian Telegraph Company (Limited). The traffic receipts for the week ending July 14th. 1882 were £1,828, after deducting the "fifth" of the gross receipts payable to the London, Platino-Brazilian Telegraph Company (Limited).

West Coast of America Telegraph Company (Limited). The gross earnings traffics and steamer, for the first half of July are £1,825, against £1,675 in the corresponding period last year.

West India and Panama Telegraph Company (Limited). The estimated traffic receipts for the half-month ended the 15th July are £2,521, as compared with £2,135 in the corresponding period of 1881. The March receipts, estimated at £7,345, realised £7,4[illegible]. For the half-month ended the 31st July are £2,400, as compared with £2,017, in the corresponding period of 18 . The April receipts, estimated at £6,858, realised £6,990.

THE TELEGRAPHIC JOURNAL AND

Electrical Review.

Vol. XI.—No. 246.

ELECTRICAL ENGINEERING.

Only a few years since young men desirous of entering the electrical profession were limited to the single branch of telegraphy, and their choice necessarily lay between becoming practical operators, skilled electricians, or manufacturers of electrical apparatus and appliances. The first-mentioned class, of course, is composed of a large body of generally intelligent men; for, wherever a telegraph line, whether overhead or submarine, exists, there must also be the operator. The skilled electricians and manufacturers are, however, comparatively few, and for some time past the former certainly have had little chance of improving their positions, simply because until recently no other branch of electrical science was open to them. During the last six years or so, such progress has been made in other ways than telegraphy of pressing electricity into our service that no person with only a moderate knowledge even of this fascinating pursuit should be unable to keep himself well employed. To young electricians of eight or ten years ago it was the height of ambition to be connected with submarine telegraphy, either in the service of the cable manufacturers or in that of some telegraph company. The work of testing cables, although somewhat monotonous, is of a more scientific, and therefore of a more interesting, character than any other branch of telegraphy. Their manufacture, too, is a subject for particular study, and a good knowledge of machinery may be gained in a cable factory. Then, perhaps, the best part of all, the life on board ship when the cable leaves the manufactory, the laying, and the homeward voyage—all this was calculated to centre the thoughts of young men engaged in electrical work, upon submarine telegraphy. The bright side of a submarine telegraph engineer's life is a very fair one, but the reverse must not be forgotten. The junior or assistant electricians should always remember that there are many slack periods in cable operations, and it is then often necessary that the *personnel* of the staff should be reduced. When such a proceeding as this took place at the period we are speaking of, it was sometimes a very difficult matter for the young electrician to find other employment. We think, however, that this is a contingency not to be feared in the present day.

We have now several branches of electrical engineering other than the telegraph, one of which at least (telephony) will become as important. What with this, electric lighting, electric railways, &c., the present difficulty is to find men competent to perform the work they are called upon to do. To prove this we have only to quote the remarks of Mr. W. H. Preece, F.R.S., who examined the candidates in telegraphy at the recent examination of the City and Guilds of London Institute.

The examiner says :—

The papers of the competitors in the first class of the Honours examination are of very fair merit. The replies given in the Ordinary, or Pass, examination are not altogether of a satisfactory character, except in one or two cases. The competitors who have taken but a low place in the second class, and those who have not passed, have, in many cases, shown that the knowledge they possess of the subjects they deal with is of a mere mechanical nature, and has simply been attained from constant practice at a particular system with which they have had to deal, and they appear to have but little notion of the broad principles upon which that particular system is founded; thus, for instance, they describe at full length, and quite correctly, the methods of making tests with particular forms of apparatus, but it is quite evident that if these tests had to be made with instruments which were slightly different in character to those described the experimenter would be unable to carry them out. In one or two instances the answers given have been merely definitions, such as would be found in any technical dictionary.

Altogether, I think the character of the papers submitted is superior to those of former years.

Again in the same examinations on electric lighting, Professor W. E. Ayrton, F.R.S., says :—

The answers to the questions set at the recent Technological Examinations in Electric Lighting and Transmission of Power show that the candidates, with a few striking exceptions, have hardly advanced beyond the mere descriptions of the construction of machines, and have had little opportunity of studying the science underlying their trade. Considering, however, how very difficult it is for students to find men who are competent, and who at the same time have sufficient leisure to teach, the answers in this subject may be regarded as fairly good.

Although these reports are not particularly favourable we trust that the students who sat at these examinations will not be discouraged with the results of their labours, but rather turn again more earnestly than ever to their studies with the assurance that a fair knowledge of electrical science should procure for them good and profitable employment. We do not know what questions were given, either in telegraphy or in electric lighting, for the purposes of the examination we have referred to, but there is usually a tendency on the part of examiners to find out, not what the students know, but rather what they do not know; or, in other words, the questions are generally set in such a way as to impress one with the profound knowledge of the examiner himself, but not so as to bring out the students' acquaintance with the every-day work he is likely to be engaged in. Enough has been shown, however, to prove that our supply of competent electricians for our most recent industries is very small, and we cannot imagine a brighter prospect for young men desirous of acquiring a profession than that of electrical engineering.

Professor Ayrton's remarks as to the difficulty of finding competent teachers is true enough so far as institute or college teaching is concerned, and therefore the youthful aspirant's best method of gaining the necessary knowledge will be to apply for a pupilage with a firm of electrical engineers or in a company. This is generally the way in which a youth is introduced into the profession of a civil engineer, and if he chooses to supplement his daily practice by private lessons, or in the classes attached to an institute like that of the City and Guilds of London, so much the better for his chances of advancement. We are still only at the commencement of the work to be done in electric lighting; electric railways, beyond an experimental trial or so, have as yet only been talked of; and the telephone industry, which should rival, if not surpass, that of the telegraph, has up to the present been crippled for reasons not necessary to refer to here. Electrical engineering may, therefore, assume at any moment an importance of such magnitude that we shall fail to take full advantages of the opportunities offered simply because we are not prepared to deal with the work put before

us. Let those men already possessed of a competent knowledge of electrical matters be ready to seize upon the first opportunity of entering the sphere of the more recent discoveries and thus gain for themselves positions they might wait for in vain in the established branches of electrical science.

ON THE ELECTROMOTIVE FORCE OF A ZINC-CARBON ELEMENT.

By M. BERTHELOT.

I HAVE measured, by the aid of a Mascart's electrometer, the electromotive force of a zinc-carbon element immersed in dilute sulphuric acid.

This force varies very rapidly by reason of polarisation, and the chemical effects which it is able to set up vary exactly in the same proportion.

When the circuit is closed the electromotive force of a zinc-carbon element much surpasses that of a zinc-platinum element, the proportion being as 1·76 : 1. It also surpasses that of a Daniell element in the proportion of 1·29 : 1—that is, it is approximately equal to the sum of the forces of a Daniell and of a zinc-cadmium element combined. At the moment when the two poles of the zinc-carbon element are connected its electromotive force surpasses even this sum, and the ratio of the said force to that of a Daniell may be as 1 : 1·37, but the force falls immediately to 1·30 or 1·29. It has then about double the force of a zinc-platinum element—*i.e.*, two zinc-carbon elements are more powerful than three zinc-platinum elements all alike plunged in dilute sulphuric acid.

But this force does not remain long at its initial value; it is sufficient to maintain the circuit closed for a few minutes by means of a copper wire of a diameter of about $\frac{2}{3}$ millimetre and 0·20 metre in length, to see the electromotive force of a zinc-carbon become equal to that of a Daniell (0·995 : 1). At this moment two zinc-carbons are surpassed by three zinc-platinums. After the circuit has been closed for some hours a zinc-carbon falls below a Daniell, the ratio being 0·83, and the electromotive force is very near that of a zinc-platinum. Lastly, after the circuit has been closed for thirty-six hours one Daniell may even surpass two zinc-carbons, at least in the first moments which follow the opening of the circuit and the connection of the two poles with the electrometer.

If I make this reservation it is because the electromotive force, which has fallen to the lowest point while the circuit is closed, tends to increase little by little when it is re-opened. The electrometer shows very distinctly these variations. Thus, after the circuit has been closed for some minutes, the electromotive force of a zinc-carbon, compared after opening to that of a Daniell in the electrometer, has been found 0·67, in a few moments 0·74, then 0·83, and, finally, 0·98, which value is approximately stationary. In the same manner, after the circuit has been closed for some hours, I have found 0·52, then 0·63, and then 0·76, a value almost stationary and answering to that of a zinc-platinum element.

It is sufficient to take the battery to pieces and steep the carbon and the porous vessels in pure water, renewed several times, for some hours in order to restore the original electromotive force. This may be done several times in succession, and, without doubt, may be repeated indefinitely.

Hence it appears that we have to do with the effects of polarisation well known to all physicists. These effects are due, as is known, to more or less complex compounds formed upon the electrodes, the presence of which gives rise to electromotive forces of a contrary direction to those of the principal action. These compounds are of two kinds, the one kind stable, but capable of being removed by washings, which restores to the battery all its initial electromotive force; the others unstable, dissociable, capable of being destroyed by diffusion, combined to the oxidising action of the air, as is shown by the variation of the electromotive force immediately after the opening of the circuit.

However this may be, the facts just detailed prove that the zinc carbon battery is unfit for any operation which requires a constant electromotive force.

Let us now show the correlative variation of the chemical effects. At the outset, theory indicates that the electromotive force of the zinc-carbon element, as it has been actually measured, should be able to produce any electrolytic reaction which consumes energy inferior to $24·5 \times 1·3 = 32$ calories per equivalent of the body decomposed, I have proved that a zinc-carbon element does not decompose acidulated water (34·5 calories), but on adding a zinc-cadmium element (8 calories, which makes 40 calories) the decomposition is produced.

Two zinc-carbon elements are equal at the outset to 64 calories, they should, therefore, decompose sulphate of potash, and, in fact, they do so. For this decomposition 51·5 calories are necessary.

We see hence the error committed by M. Tommasi, when he believes that he has produced this decomposition by the mere force resulting in two consecutive couples from the formation of sulphate of zinc from metallic zinc and dilute sulphuric acid. In reality such a force is incapable of producing any electrolytic decomposition which consumes more than $19 \times 2 = 38$ calories per equivalent. If two zinc-carbons decompose sulphate of potash whilst two zinc-platinums are unable, it is because the chemical reactions which develop the electromotive forces are not the same in the two systems.

Let us pursue this demonstration: as the electromotive force of the zinc-carbon decreases, its chemical power diminishes. After some hours, when the measurements show that the force of the two zinc-carbons is fallen below that of two Daniells (49) they cease to decompose sulphate of potash (51·5). When it is reduced to that of two zinc-platinums (36 — 38) they still decompose acidulated water (34·5), but it is necessary to connect to them two zinc-cadmiums ($38 + 16 = 54$) to decompose sulphate of potash the addition of a single zinc-cadmium being insufficient.

If I have thought it necessary to insist upon these facts, upon the direct measurement of the electromotive forces and on their continuous correlation with the energy brought into play in chemical reactions both within and without the pile, it is that there may exist neither doubt nor confusion on the fundamental laws of electro-chemistry.

M. Tommasi replied to this as follows:—

Hitherto it has always been admitted that in any element whatsoever the nature of the positive electrode had no influence upon the electromotive force, provided that this electrode was not attacked by the exciting liquid. In the bichromate of potash element alone a difference has been observed in the electromotive force, according as the positive electrode was of platinum or of carbon. I have already pointed out this fact, and I shall return to it in detail in speaking of the chromic acid element. As for Smee's element with dilute sulphuric acid, it has always been believed that the nature of the positive electrode does not sensibly affect its electromotive force. "It is thus," says M. Du Moncel, "that silver, lead, carbon, copper, aluminium, iron in the passive state, have been able to be substituted for the platinum of Smee's battery, without any difference in the electric action other than that derived from the polarisation which these plates might effect.

It appears, therefore, that the augmentation of the electromotive force which I have demonstrated in the zinc-carbon element constitutes a novel fact, not without a scientific interest.

It is known to all that the electrolytic work effected by an element is so much the more considerable as its electromotive force, measured by the electrometer, is more intense. Consequently it is not surprising that M. Berthelot has found, by means of Mascart's electrometer, that the zinc-carbon element has a greater electromotive force than a zinc-platinum element. Since it is known, according to my experiments, that the chemical work produced by the zinc-carbon element is much greater than that obtained with the zinc-platinum element, it would have been, indeed, strange and contrary to all known facts if the electrometric determinations executed by M. Berthelot had proved the contrary.

I had intended to complete my researches on the zinc-carbon element with electrometric determinations; but as M. Berthelot has anticipated me it only remains for me to observe that all the experiments which this *savant* has

described in no way tell against my researches, but, on the contrary, give them a greater degree of certitude. I have never said that a zinc-carbon element was equal to a zinc-platinum element, for the simple reason that I have proved quite the contrary. I have certainly not sought to show that the zinc-carbon element produced an electromotive force greater than the zinc-platinum element, in order to infer that these elements were mutually equivalent.

In my last note I have merely brought forward facts, and these facts are perfectly exact, as M. Berthelot has been able to convince himself when he repeated my experiments, in order to complete them by electrometric determinations. As to the interpretation of these facts I have not said a word, and consequently M. Berthelot ascribes to me things which I have never thought.—*Comptes Rendus.*

GARNIER'S COMBINATION RHEOSTAT.

THE combination rheostat of M. Garnier, which was exhibited at the Electrical Exhibition at Paris in 1881, has for its object the immediate combination of a number of resistances, so as to form a total equal to any required value. The resistance boxes usually employed contain bobbins which are multiples of an arbitrary unit, the ohm, for example, and are so selected, that they can be grouped together, so as to form any required total; by this arrangement any resistance whatever, from the unit upwards and varying by equal graduations, can be obtained. Thus, with the multiples which have been long employed, namely, 1, 2, 2, 5—10, 20, 20, 50—100, 200, 200, 500, any number from 1 to 10,000, each differing by one unit, can be formed, provided that one does not exceed twice the last term of the series. But if it is required to form rapidly any given resistance, it is difficult to avoid various changes of the plugs, in order to obtain the required combination; this operation is analogous to the operation of weighing, and one knows how much time is lost in the employment of a balance and marked weights.

With the cylindrical rheostat one can form immediately any arbitrary rsistance, and can also increase or diminish it regularly by degrees corresponding to any decimal unit. This apparatus consists of a certain number of dials, units, tens, and hundreds, for example, each having eleven divisions (0 to 10), over which a pointer moves. Each needle is mounted on the axis of a cylinder, which has for its object, in each of its positions, the introduction of such bobbins as will together form the exact resistance indicated by the pointer. The "unit" cylinder is connected to bobbins 1, 2, 2, 5; the "ten" cylinder is connected to bobbins 10, 20, 20, 50, and so on. It will be sufficient to explain the construction of one of these cylinders. Let us suppose the four bobbins to be connected, as indicated by fig. 1, to five metal plates, A, B, C, D, E; if these plates

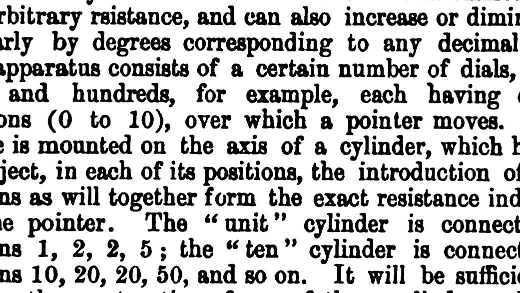

FIG. 1.

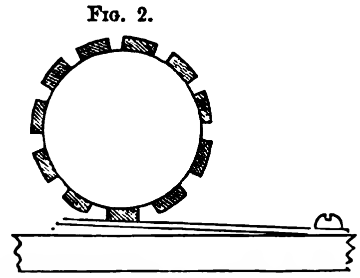
remain insulated from each other, the circuit M, N, contains the resistance of all the bobbins, that is to say, 10 ohms; if a combination is effected by metallic connections, of inappreciable resistance, of the three plates, C, B and E, for example, then the resistances, 5 and 2, become cut out of the circuit, and a resistance of 3 only remains in circuit; thus by a proper union of the plates any resistance from 0 to 10 can be obtained. The metallic connections are effected by bands of metal fixed around the circumference of the combining cylinder (fig. 2), the development of which is shown by fig. 3.

The five plates of fig. 1 are formed of five springs which press together on the connecting plates of the cylinder. It can easily be seen that the lengths and the positions of the metal strips are arranged so as to introduce in the circuit those bobbins the sum of whose resistances forms the series of numbers 0 to 10. The cylinder, it is evident, is made of

FIG. 2.



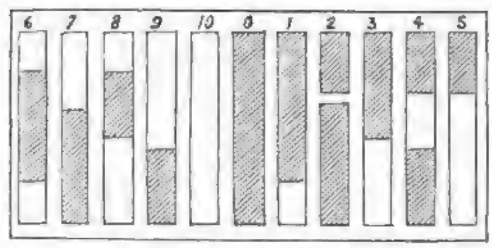


FIG. 3.

an insulating material, wood or ebonite. The plates, A, B, C, D, E, are fixed at one extremity and have sufficient elasticity at their free ends to allow of the rotation of the cylinder, and of the various strips of metal being brought into the eleven different positions which they can take up.

The "ten" and "hundred" cylinders are arranged in the same way as that for the "units," and the circuits, M, N, of the three cylinders are alike. The cylinders can be placed in a box arranged like a Wheatstone bridge, and furnished with proportional branches. The same arrangement of cylinders can be equally well applied to the grouping of condensers.—*Annales Télégraphiques.*

THE ELECTRIC LIGHTING BILL.

IN the House of Lords on Thursday, August 3rd,

Lord Sudeley moved the second reading of the Electric Lighting Bill. The public are by this time so familiar with this measure that it will not be necessary to repeat the noble lord's observations at any great length. He pointed out the rapid and extensive growth of electric lighting in recent years, and the necessity for legislating upon the subject in such a way as to prevent the creation of such monopolies as those of gas and water—not always to the benefit of the public. He recited the leading provisions of the bill as it left the other House, and related the proceedings both of the recent Committee and of that in 1879. In support of the licences provision, he argued that the necessity of companies going before Parliament and being prepared for an outlay at once of £10,000 or £12,000 would practically retard the development of electric lighting to a serious extent, whereas the proposed system of temporary licences would be both simple and cheap, and therefore of great advantage to the community at large. The objections of the gas companies he dismissed with the remark that they naturally did not like an innovation which threatened their interests, although they had no real legal monopoly in the supply of light; and in conclusion he promised that the Board of Trade, not desiring to hamper the operations of electric companies, would be ready to modify any terms that might be found too hard.

Lord Emly did not advance any obstacles to the bill, but he regretted that it had come up so late that it could hardly receive adequate consideration. He likewise regarded the case of the gas companies lightly, but he expressed a fear lest the clause (27) which would enable an early purchase by local authorities might deter people from entering upon undertakings, especially the system being still largely experimental, could hardly yield any return in less than fifteen years, when undertakings could be bought up without compensation.

The Earl of Crawford and Balcarres, who, as Lord Lindsay, sat on the Committee of 1879, also objected to the 27th clause, pointing out that although a fair price would be given for an undertaking, yet plant and machinery would be depreciated by something like 50 per cent., which would, of course, be so much loss to the original company. For that reason he feared the purchasing powers would be a serious hindrance.

[illegible]

THE ELECTRIC LIGHTING OF THE COMPTOIR D'ESCOMPTE BY BICHROMATE BATTERIES ON THE JARRIANT AND GRENET SYSTEM.

CAN batteries charged with liquids be employed for electric lighting on a considerable scale without the expense involved in their use being out of all proportion to the result obtained? All the experiments made up to the present have given a negative res[illegible] t this has not prevented inventors from continuing [illegible] ches in this direction, and in the ardour of [illegible] ions these *savants* have persuaded capitalis[illegible] s to make the necessary sacrifice in order t[illegible] a practical shape, and to bring them within [illegible] mplished facts. Considered entirely

[illegible] The solution of bichromate of soda is prepared beforehand in large quantities at the workshop and is pumped into large reservoirs at the top of the building. From there it is brought below to each battery by a special pipe service—very well arranged although rather complicated—provided with taps of ebonite and pipes of india-rubber.

The fresh liquid can be used three times over. The first time it flows at the rate of 20 litres per hour, and through the battery of 48 elements; the second time at the rate of 30 litres, and the third time at the rate of 40 litres. By adding a little of the fresh liquid it can be used over for a fourth time. When thus used it drains through at the rate of 60 litres per hour per battery; after which the liquid goes through a process of regeneration. MM. Jarriant and Grenet profess to be in possession of an economical process for the regeneration of the liquids, a process which allows of the separation of the chrome and the zincs from the alkaline sulphate, by a new method. This process, which is no longer a secret, being patented by MM. Jarriant and

Grenet, appears to us to be decidedly complicated. The following is a rapid enumeration of the manipulations necessary to effect the regeneration of the products :—

1st. The saturation of the excess of sulphuric acid by carbonate of lime ; the precipitation of the sulphate of lime, of the oxide of chrome, and of the carbonate of zinc. The liquor which remains contains alkaline sulphate.

2nd. The decantation, concentration, and crystallisation of the alkaline sulphate.

3rd. The separation of the carbonate of zinc from the oxide of chrome, and of the sulphate of lime, by a certain quantity of sulphuric acid, which is calculated exactly to transform the carbonate of zinc into sulphate of zinc. The liquor which remains contains sulphate of zinc, which is concentrated after decantation for crystallisation.

4th. The desiccation, pulverisation, and mixing of the sulphate of lime and oxide of chrome with quicklime and the alkaline carbonate.

5th. The calcination of the above mixture on the hearth of a reverberatory furnace and the extraction of the chromate by *known processes.*

We see that the generation of the products is by no means a simple operation, involving, as it does, five processes, not counting the *known processes,* and the carriage of the liquids from the Comptoir to the workshop, and from the workshop to the Comptoir.

Let us now return to the batteries. We can see that the overflow pipe serves to maintain the level constant in the elements in proportion as they are filled with fresh liquid ; this circulation of the liquid serves in a certain degree to keep the current constant, a constancy still more preserved by an aeration produced in each element by means of two tubes of ebonite, which plunge into the bottom of the liquid. In order to obtain the air necessary for the aeration without special expense, advantage is taken of the compressed air used for the pneumatic transmission of messages between the various offices of the Comptoir.

Under ordinary conditions, the volume of air furnished to each battery is about three cubic metres per hour, under a pressure equal to the height of the liquid in the elements, or about 15 to 20 centimetres of water.

The installation is completed by a supply of water for cleaning the elements, and a double sink for the discharge ; one of the sinks is employed for remixing the liquid for charging the batteries, the other holds the water for washing the elements and conducts it into the sewers.

The negative pole of each battery is connected to a common lead wire, the positive pole is joined to a commutator which has fifty bars. The feeding apparatus is also connected to a common negative lead wire, and the positive poles are attached to the same commutator ; the batteries occupy the horizontal bars and the lighting apparatus the vertical ones. We only require, therefore, to place a peg where two given bands meet in order to establish communication between a battery of a given number and a given series of lighting apparatus. Either the Swan incandescent lamps or the arc lamps of Siemens, Gravier, &c., are used as occasion requires. Each battery of 48 elements in series has an electromotive force of 82 volts, and can give as much as 24 ampères on a short circuit. We see by these figures that a single battery is sufficient to feed a number of incandescent lamps or a voltaic arc with 10 carbons of 10 millimetres, which works very well with 10 ampères. We can besides group several batteries in tension or in quantity as occasion may require, in order to supply more powerful arc light or a larger number of incandescent lamps ; it is with this object and also for the purpose of having a few reserve batteries that the commutator has only 50 positions, although the complete installation should have 60 batteries.

The employment of a distinct wire for each lamp, and of a wire for each battery, the negative being in common, constitutes rather a serious expense at the first installation, but it has the advantage of rendering the apparatus, lamps, and batteries absolutely independent of one another. In case of accident it is easy to localise it and repair it, and thus the accident is never very serious. An indicating table, arranged opposite the Swiss commutator, enables the lighting of any given hall to be regulated from a distance ; the workman charged with the superintendence of it knows which are the right batteries to work, and has only to place the pegs. Besides, the lamps can be lit or extinguished at will by commutators arranged in the hall, when communication is established between a battery and a given circuit by means of the Swiss commutator.

Such is the principle of MM. Jarriant and Grenet's installation of bichromate batteries for the lighting by electricity of the Comptoir.

The future will throw some light on the economic view of the question, concerning which we have as yet very vague ideas. This point will decide the future of the installation ; but whatever fate may be reserved for it, it was no less interesting to describe the general outline of an installation in which for the first time for industrial purposes and practical application an electrical energy of fifty horse-power has been produced by the employment of liquid batteries.

Correspondence should arrive not later than Tuesday morning if it is desired to appear in the following number.

A MAGNETOMETER FOR THE DETERMINATION OF THE POLE STRENGTH OF MAGNETS.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—While occupied in the study of magnetism I have devised a little instrument by which the pole strength of magnets may be determined in absolute units. As it is not difficult to arrange and gives good results I venture to send it to your Review, as it may possibly be of use to some who are engaged on the subject of magnetism.

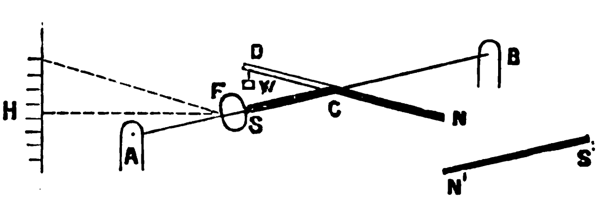
Yours faithfully,

FREDERICK JOHN SMITH.

Taunton, *July 28th*, 1882.

DESCRIPTION.

A magnet of rectangular shape, S C N, having a brass counter weight, D C, equal in length to C N, is attached to a torsion wire, A B, stretched between two pillars ; it is furnished with a mirror scale and lamp, F H. The magnet is made of rectangular form in order that the south pole may be placed in the axis of the wire, and thus out of the influence of side pull of the magnet, N′ S′. By a milled head at A different amounts of torsion can be given to the wire. To use the instrument the magnet, N′ S′, is removed, and the magnet is placed in a horizontal position, and the scale reading taken. A known weight, W, is now placed at D, and the new scale reading recorded. The weight is now removed, and the magnet, N′ S′, of equal pole strength is slowly raised under the N pole of the rectangular magnet until the same reading on the scale is obtained as when the weight was on, thus the repulsion of the two equal poles is equal to the effect of the weight, W. (No great difficulty is found in making magnets of equal pole strength by a peculiar process.)



Now, we know that the force, *f*, acting between magnetic poles it stated by the formula

$$f = \frac{s \times s'}{d^2}$$

where S S′ denote pole strength and *d* distance between them in this instrument, $s = s'$, so the formula may be written

$$f = \frac{s^2}{d^2}$$

and *w g* can be written for *f* where *w* denotes the numerical

value of the weight and g = gravity force ; from this s is at once known ; the weights are part of the gramme, and the distance, d, is measured in centimetres. The rectangular magnet has been used by me to construct a virtually one-pole magnet some years ago. When the strength of one-pole has been determined other magnets and solenoids can at once be compared with it, the magnet, N′ S′, is raised into position by a micrometer screw.

THE RIVAL TELEPHONE COMPANIES.

To the Editors of The Electrical Review.

Sirs,—The public has no doubt heard with no unmixed pleasure the announcement by "The London and Globe Telephone and Maintenance Company (Limited), that it intends to construct and maintain and provide telephone lines and exchanges on more advantageous terms than those of existing companies, so as to place the telephone within reach of all classes of society." The United Telephone Company has lost no time, however, in bringing to the notice of the public several judicial facts bearing upon certain of the patents advertised as part of the purchase to be made by the new company for the moderate sum of £130,000. The public, however, are too familiar with the preposterous claims heretofore set up by the United Telephone Company to give credence to all that company may publish. In this case, however, it would appear that Mr. Justice Fry did decide that the Hunnings' transmitter, "having the combination of a diaphragm with a tension regulator," was an infringement of Edison's patent, which patent, however, Mr. Justice Fry felt compelled by the evidence before him to declare to be void, because of a claim in it not justified by the provisional specification.

Now, however, the fiat of the Attorney-General has been granted, and the objectionable claim of Edison has been disclaimed—and his patent stands valid—and any transmitter combining a diaphragm with a tension regulator, be it Hunnings', Dolbear's, or Ander's, is clearly an infringement of Edison's patent, according to the decision of Mr. Justice Fry.

When schemes, for which the too easily gulled British public are asked to subscribe, embrace the development of scientific discussion, it might be advisable for it to consult scientific publications instead of the financial newspapers of the day.

JUSTICE.

10th August, 1882.

MULTIPLE TELEPHONE SIGNALLING.

To the Editors of The Electrical Review.

Sirs,—I beg to offer a few remarks on the article describing Mr. Kettell's individual telephone call and signal, in the number for July 15th. It is a difficult task to give a detailed description of such an instrument, and great credit is due for the lucid manner in which the working was explained.

"The proof of the pudding is the eating." I therefore speak with all deference to the statement that the system has been in practical use for over a year and a half, and has proved a perfect success, but it would appear to me that the following difficulties would seriously affect the prospect of its general introduction into this country :—

1. Each subscriber could interrupt and overhear the conversation of any other subscriber on the same line.

2. Any mischievous person might without fear of detection, ring up all the subscribers on the line by pressing his button when he observes the clockwork going.

3. The subscriber who first calls is kept waiting with his telephone to his ear until the exchange answers him, and after that until the attention of the person he wishes to speak to is gained. This is very wearisome compared to the separate line system, under which the subscriber simply rings up the exchange, and having given the number of the firm he requires, may leave the instrument until his bell is rung again as a warning that the person he asked for is in readiness to speak.

4. No. 1 rings up the exchange, and in doing so sets all the discs to "line occupied"; he says he wants to speak to No. 5 (who is on the same line). How is the attention of the last-named to be obtained ? Must not the exchange go through the process of clearing the line, and then ring him up by pressing the button, p, as in other cases ?

5. The amount of work thrown on the operators would appear to be very heavy ; they would not only have to wait until the clock ceased running before connecting two lines together, but would have to send clearing currents after each of them after the expiration of the three minutes allowed for speaking.

One man could not, I suppose, do the switching for more than thirty subscribers (six lines of five stations each).

6. In the event of the person who is being called not attending to the first ring of his bell, a clearing current would have to be sent from the exchange along the line, and the process of ringing him gone through again, during which time the subscriber who first called would be patiently waiting with his telephone to his ear.

Taking the difficulties above enumerated into consideration and the thousand and one peculiar incidents which occur in the use of exchange lines, I do not think that we have yet arrived at a satisfactory solution of the problem how to connect several subscribers up to an exchange on one wire, and at the same time give them an efficient service.

The best arrangement I have yet seen for the purpose was that designed by Messrs. Brown & Saunders, and shown at the recent Crystal Palace Exhibition. A description of it was given in one or two of the scientific papers. The following is an extract from one of these, from which it will be seen that very important results are obtained :—

"The object of this apparatus is to place a number (say 11) telephonic subscribers in series on one line, in such manner that either one may call up and speak to another without disturbing the remainder and without the possibility of any of the remaining subscribers either calling or overhearing the conversation or of interrupting by ringing until the caller clears the line.

"An automatic arrangement is also provided which ensures that the caller shall not neglect to so clear the line when he has finished speaking."

The telephone industries are now assuming very large proportions ; a great variety of opinion exists as to the best form of switch boards, subscribers, instruments, transmitters, line work, &c. It appears to me at once strange and regrettable that in this country telephonists have not before exchanged views and discussed these questions through the medium of a paper. I am, Sirs,

Yours faithfully,

WM. L. MADGE.

Belfast, *August 5th*, 1882.

ELECTRIC LIGHTING.

To the Editors of The Electrical Review.

Gentlemen,—In Mr. Humphreys' letter to your journal of the 5th inst., making, no doubt, allowable excuse for the Brush failures, he says, "In this the first attempt ever made at street lighting in this country." Now, "fair play is a jewel," and long before "Brush" was ever heard of the "Jablochkoff" system lit the greatest thoroughfare in Europe, and has done so for nearly four years, and never had an extinction, until for once lately, by the piston rod of the engine breaking.

Faithfully yours,

R. SPEAR BEGBIE.

August 5th, 1882.

THE CITY AND GUILDS OF LONDON INSTITUTE TECHNOLOGICAL EXAMINATION.

To the Editors of The Electrical Review.

Sirs,—In "Fareham's" interesting and suggestive article in your last issue, on the recent technological examination held under the auspices of the City and Guilds of London Institute, he mentions what appears to be an anomaly in the result of that examination. The particulars which he gives of this case tally exactly with those known to me, and if I am right in believing they refer to the same circumstances, perhaps, as one better acquainted with the facts, I may be permitted to correct the erroneous view he has formed of them, and which he may have led readers to share. Your correspondent is quite wr-

stating a clerk of only six months' study managed to secure an honours' "pass," while another of six years' theoretical and practical experience was plucked, and using this as an argument to show the weakness of the present examinational system. The truth is, the successful clerk has had a few years of study, and it has not been all theoretical, though he has never acted as a "test" officer. "Fareham" is not very successful in explaining the cause of the failure of one so deserving of honours. Is it conceivable that one who five years ago secured a first class certificate in electricity and magnetism could have failed to pass in honours through inability to express himself? But, whatever may be the true reason, it is scarcely fair to make use of the result to cast reflections on the quality of the knowledge possessed by a successful candidate, and to question (even though indirectly) his right to an honour which he has striven hard for.

"Fareham" assures us this "anomaly" is by no means an isolated one, but I am inclined to think that if the others were examined into they would admit of a more creditable explanation. I do not believe that any one, however excellently crammed or coached, could pass ordinary or honours in telegraphy without a considerable practical knowledge of the subject.

ABA.

August 7th, 1882.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—The keynote of the annual wail from disappointed teachers has been struck by your correspondent "Fareham," in a letter which is valuable, so far as the tabulation of the examination results and his remarks thereupon go, but which, in other respects, has not a very logical connection between its premises and conclusions.

A quotation is made from an address of Colonel Webber, in which instruction in the workshop and laboratory, and the hand-in-hand march of *theory* and *practice* is advocated; and your correspondent goes on to state, that such a course cannot be gone through at the City and Guilds classes so long as the present system of examination continues, so long as students gain prizes, and teachers grants, by mere "cram" knowledge. I venture to think this charge against the City and Guilds examinations is quite unfounded. The questions set at the May examination seem to have been specially directed against "cram," and no student who had not combined a practical, with a theoretical study of the subject, could have answered them satisfactorily.

To support his case, "Fareham" cites an instance where a student, who has devoted five years of his time to the study of technical telegraphy, and who discharges from time to time the duties of a testing officer, was plucked, while a six months' (?) student gained an honour's place. "There is but one explanation of such an anomaly," adds your correspondent, "and it is the failure of the five years' student to express himself on paper."

Practical examinations are, therefore, demanded. Without discussing whether a student who fails at a written examination would be more successful at an oral one, I would point out that this "anomaly" is singularly at variance with the position taken up by "Fareham," proving, as it does, that there may be too much *practice* and too little *theory*. There are many very good testing officers who carry out their duties with care and exactitude, and with a certain amount of "knowingness" to boot, whose real knowledge of the principles of testing never rises above the rule of thumb; and probably the five years' student's relationship to this class of technical officers may account for his inability to express himself on paper.

Undoubtedly a great cause of failure at these examinations is the temptation which first year's students have to compete in the honours grade. This is due to the practice of carrying on the teaching for both grades at the same time, there being no distinction between ordinary and honours subjects in the syllabus supplied to teachers. Were the City and Guilds Institute to take an example from the Science and Art Department in this respect, and issue a syllabus stating clearly and fully the ground to be covered in each grade, teachers and students would be alike benefited. The teaching would then be thorough and definite, the class being necessarily elementary or advanced. It would not then be needful to hurry over the entire subject in one short session as at present, and students would no longer have it in their option to bring discredit on themselves and their teachers by aspiring beyond their qualifications.

Yours truly,

MAGA.

THE UNITED TELEPHONE COMPANY.

To the Editors of THE ELECTRICAL REVIEW.

DEAR SIRS,—I venture to send to you a few comments on the reports made by the directors of the United Telephone Company (Limited) to the two general meetings of their shareholders, held respectively on August 9th, 1881, and on August 1st, 1882.

The nominal capital of this company is £500,000, of which it appears that £400,000 had been paid in for shares prior to August 9th, 1881, the date of the first general meeting. In that report it was stated by the chairman that in the months of May, June, and July, 1880, there were 609 subscribers; in August, September, and October, 707; and in December, January, and February, 820; and on August 9th, 1,052. The total receipts from all sources were £20,644, and the working expenses were £20,273, thus showing a surplus of £371 over and above working expenses, with which a dividend of one-twelfth of one per cent. might have been paid on the £400,000 paid-up capital—a result which could not have been very satisfactory to the 600 shareholders. But the Lancashire and Cheshire Telephone Company fortunately arrived in time to assuage their grief, and a bonus of 10s. per share upon the issued shares of the United Telephone Company was paid out of the sum of £50,000 cash received from the Lancashire and Cheshire Telephone Company, leaving a balance of £10,000 to be carried to the reserve fund, applicable to the general purposes of the company. The United Telephone Company received also from the Lancashire and Cheshire Telephone Company 50,000 of their fully paid-up shares of £1 each.

At that meeting the chairman said, "I don't want to bother you with figures, but here are some remarkable statistics compiled by our auditors, showing the increase in the number of our subscribers, and, above all, the decrease of the expenses." The few figures which the chairman did put forth must have bothered greatly the shareholders, as those figures gave to the shareholders the not welcome information that the company had earned only £371 during the year, notwithstanding the "remarkable statistics compiled by the auditors." The one great fact which stands forth conspicuously in that report is that the United Telephone Company, with 1,052 subscribers to their London exchange, earned only enough to cover their working expenses.

Now I turn to the report submitted on the 1st inst. to the general meeting of the shareholders.

The receipts from all sources for the year have been £42,624, and the working expenses £21,050; the balance net revenue, £21,945, from which a dividend of 5 per cent. was paid on £400,000 paid-up capital, leaving a balance of £1,945 to be carried forward.

It is no doubt gratifying to the shareholders that their telephone exchange has paid them a dividend of 5 per cent., less income-tax.

Is it possible that the 600 shareholders who have paid £400,000 into this company's coffers can be satisfied with a dividend of 5 per cent. when they consider that Bell's patent will expire in eight years, in December, 1890, and Edison's patent in July, 1891, for which the company have paid fabulous sums of money; to which must be added the money paid for Crossley and Blake's patents, making a total of nearly £300,000, which large sum of money will have entirely disappeared in nine years. No mention is made in either of the reports of any provision for a sinking fund to make good to the shareholders the capital sunk in patents. Perhaps they are satisfied with the *patent* sinking fund they have. The report announces the formation of two new companies affiliated to the parent company, viz., the Telephone Company of Ireland, nominal capital £200,000, of which the United Telephone Company receives 87,500 shares of £1, and a payment of annual royalties on each instrument used; the other company is the Western Counties and South Wales Telephone Company, nominal capital

£275,000, of which the United Telephone Company receives 125,000 shares of £1, and annual royalties on each instrument used. If these companies can earn dividends of course the United Telephone Company will receive its share of them. That the prospect is good may be doubted, when the prolific parent company's exchange in London, with its 4,000,000 population, could only pay its expenses during the first year, and only 5 per cent. for its second year.

The abnormal high price of the shares of this company is an enigma.

The statement made by the chairman at the first general meeting that the United Telephone Company had secured in its own hands "all the patents of value in this country, and that it has the *monopoly* of the telephone in the United Kingdom," no doubt has had its effect upon the general public, who, believing in those (I may say) preposterous claims, fancy they hold a monopoly of telephony in the United Kingdom. Even in the report submitted on the 1st inst. that illusion is attempted to be kept up by the remarks of the chairman, that "if any persons do obtain a licence from the Postmaster-General they will first have to obtain proper instruments to carry out the business, which I think at this moment is rather *a doubtful enterprise on their part.*"

It is possible—aye, probable—that the general public will sooner or later be convinced that this company's security in a monopoly is a myth, and will learn to its cost that the fancied security in a monopoly expressed by their chairman resembles closely the fancied security of the ostrich, which sapient bird hides its head and believes its pursuers cannot see it because it has concealed its own eyes.

The telephone is an useful instrument, and will become a necessary one so soon as instruments can be procured at a reasonable price, which desirable end cannot be obtained from a company which has paid hundreds of thousands of pounds for a fancied monopoly.

COMMON SENSE.

London, *August 9th*, 1882.

NOTES.

ERRATUM.—ELECTRICAL REVIEW.—In the letter of Prof. Silvanus Thompson, headed "The Telephone," in our issue of August 5, 1882, p. 87, col. 1, line 12, for "1863" read "1861."

DANGER FROM ELECTRIC LIGHTING.—We read in the daily press that an accident, attended with fatal results, occurred on Sunday evening, in the Tuileries Gardens, in Paris, during the display of fireworks. Two men, in attempting to climb over the railing, caught hold of the electric wire used for the illumination of the grounds, and were struck dead on the spot, all efforts to restore them to life proving ineffectual.

OPPOSITION TO A PATENT FOR IMPROVEMENTS IN DYNAMO-ELECTRIC MACHINES.—In the opposition to the application by Mr. W. H. Akester, of the Universal Electric Light Company, Limited, for letters-patent for improvements in dynamo-electric machines, the Attorney-General heard counsel for parties on Saturday last. On account of the allegations and counter-allegations in the declarations, while permitting the patent to proceed, he declined to allow the applicant costs. In reply to counsel on both sides, the Attorney-General stated that as his tribunal was one before which parties could not be cross-examined upon oath, he should for that reason allow the patent to proceed, leaving the applicant to his remedy in open court. Application for provisional protection was made and granted on 17th December, 1881 (No. 5525), and on notice to proceed being given, opposition was lodged against the patent being sealed by Mr. David Graham, electrical engineer to the Railway Appliances and Electric Company (Limited). The grounds of opposition were: (1) That the patent was an infringement of a patent which Mr. Graham had previously acquired—this ground was afterwards abandoned; and (2) that the invention was that of Mr. Rankin Kennedy, another *employé* of the company, and not the invention of Mr. Akester, while the latter maintained that the invention was exclusively his own. The application and opposition have been fought keenly for several months past, so great is the intrinsic value of the invention believed to be, many declarations and exhibits having been made on both sides. The matter is by no means finally disposed of, and Mr. Kennedy has upon the advice of his counsel instructed his agent to oppose the applications before the Lord Chancellor.

EXTINGUISHING THE ELECTRIC LIGHT.—For maliciously extinguishing the electric light in St. Enoch Station, Glasgow, Peter Smith, who had been an *employé* of the Glasgow and South Western Railway Company, was fined two guineas, with the alternative of twenty days' imprisonment, at the Central Police Court of Glasgow on Monday last.

THE ELECTRIC LIGHT AT EDINBURGH.—After the unfortunate failure of the electric light as an Edinburgh street illuminant, it is gratifying to learn that the installation made twelve months ago at the Waverley station of the North British Railway Company has been so successful that the company has decided that "the light of the future" shall shed its rays not only over the main portion of the station, but even unto its outermost platforms.

ELECTRIC LIGHTING IN THE ROYAL AQUARIUM.—We understand that a prize of 100 guineas is to be offered for the best and most durable system of incandescent electric lighting in the forthcoming exhibition, to be held at the Royal Aquarium. Each competitor is to be limited to 100 lamps, and these are to be kept in action during the whole time that the exhibition is open. Tests on each system will also be taken at intervals. We believe that it will be stipulated that when each installation is fairly started no part of it shall be subject to any additions or alterations unless duly reported.

THE WINTER ELECTRICAL EXHIBITION AT THE ROYAL AQUARIUM.—Doubtless most of our readers are already acquainted with the contents of the prospectus issued by the directors of the Royal Aquarium. The space at command being limited, the installations of individual exhibitors will be restricted, so that all may be placed upon an equal footing. Attention will be concentrated more particularly on electrical matters which have hitherto been imperfectly touched upon. Copies of the prospectus, together with a lithographed plan of the Aquarium building, may be obtained on application to Mr. Will. D. Gooch, the engineer to the exhibition.

ELECTRIC LIGHTING IN LIVERPOOL.—The Pilsen, Joel, and General Electric Light Company, Limited, on the evening of Wednesday, the 2nd inst., lighted the extensive music warehouse of Mr. W. Lea, in Church Street. Four Pilsen arc lamps, each giving a stated light of 2,000 candle-power were employed, the current being produced by a Schuckert 4-light dynamo-electric machine, driven by a five horse-power Ransome's engine. This and the machine were placed in School Lane, and the length of cable required was about 500 yards. We believe the installation is under the control of Messrs. Woodhouse and Rawson, electrical engineers and contractors, the work however being carried out under the direction of Mr. R. H. Newington. A large number of ladies and gentlemen (including the Lord Mayor, the Lady Mayoress, and several councillors), were present at the invitation of the chairman and directors of the company. These were received by Mr. Beattie, the company's London representative, and Mr. Rawson. We understand that the inauguration passed off in a most successful way, and great satisfaction was expressed by all present at the effect produced by the Pilsen light.

THE ELECTRIC LIGHT AT PAISLEY.—The mansion of Mr. Archibald Coats, at Woodside, Paisley, has now been fitted throughout by the Edison Electric Light Company with the electric light. The total number of lamps fitted up is 200.

THE ELECTRIC LIGHTING BILL.—Two letters in the *Times* of the 8th inst. on the above subject are worthy the

attention of all connected with the electric lighting interests. One is from Mr. Moulton, Q.C., and is written in a similar strain to that of Sir Frederick Bramwell, published in the same paper a short time previously. The second is from Mr. Arnold White, the Secretary to the Edison Electric Light Company.

ELECTRIC LIGHTING IN AMERICA.—The Hotel Vendome in Boston has within the last few days been provided with sixty of the Edison Company's incandescent lights, each having a power of sixteen candles. Mr. William W. Munroe, the Boston agent of the company, says the Edison Company now can fairly claim that it has passed its experimental age, and with its system perfect in all details is now really achieving high practical results. The incandescent light, he adds, as used by the Pemberton, Arlington, Merrimac, and Worrumbo mills, and by numerous prominent business houses throughout New England, is daily proving that it is superior to gas in all ways, while at the same time more economical. We read also that by September one thousand houses in New York will be supplied with the incandescent light in Edison's first district. Since June 1st, according to an American contemporary, Mr. Edison has filed fifty-one applications for electric lighting patents, and that he has now a grand total of 109 patents in this subject alone. Edison lamps have been used for some months in the offices of the Philadelphia *Ledger*, and the plant is now being doubled. The *Record* has also ordered an installation. The United States Illuminating Company is also apparently doing a considerable amount of business. Machines and lamps under the Maxim, Weston, and Farmer patents are manufactured for the company by the United States Electric Lighting Company, and not less than 160 miles of conducting wires for arc lights have been supplied.

OVER FIVE THOUSAND ELECTRIC LIGHTS IN ONE BUILDING.—The Mills Building, Wall and Broad Street, says the *Scientific American*, has been wired for 5,588 Edison lamps. As this is the largest enterprise of the kind ever undertaken the details may prove interesting. The conductors consists of 1,650 feet of Edison's patent electric tubes, 628 feet of lead pipe containing taped wires thoroughly insulated, 23,658 feet of zinc tubes, 75,909 feet of wire conductors, and 24,162 feet of wooded receptacles, placed between the floors, to hold the system of distributed wires. The total amount of wires used was 3,774 lb., besides 48 vertical main cut-outs, and 253 division cut-outs.

THE TELEGRAPH AND ELECTRIC LIGHT IN EGYPT.—The mounted portions of the telegraph troop Royal Engineers, consisting of about seven officers, 184 non-commissioned officers and men, and 65 horses, with two field telegraph equipments complete, and the field pack of the Royal Engineers, including one officer, 33 non-commissioned officers and men, and 26 horses, under the command of Major Sir A. Mackworth, marched from Aldershot on Saturday last, *en route* to the South-West India Docks, London, where they will embark to-morrow in the steamer *Oxenholme* for conveyance to the East.

The telegraph steamer *John Pender*, which arrived at Alexandria with a sufficient supply of cable on board for the projected line between Suez, Port Said, and Alexandria, was recently engaged in important work for the Eastern Telegraph Company between Lisbon and Land's End. Immediately on the decision of the Government, and from the urgency of the case, she was ordered to Alexandria.

A portable steam-engine has just come out for working an electric machine.

Izzet Effendi, Director of the Telegraphs, sent a staff of *employés* on the 3rd inst. to lay and open a cable between Jeddah and Souakim.

The *Superb* used her electric light on the night of the 9th inst. from where she lies, off Count Zizinia's house, but whether it was an advantage or otherwise is an open question. From the distance she had to throw the rays it was impossible for those on board to use the light so as to be of the greatest assistance to our sentries. The officer in charge of the picket said that several times the electric light was thrown on his own men, who thus were themselves exposed to view, and at the same time were unable to penetrate the darkness beyond. This is manifestly turning a valuable appliance into a source of danger, and it shows the inutility and even peril of using the electric light indiscriminately. Arrangements have been completed for throwing the electric light over the enemy's lines from Ramleh.

MOVEMENT FOR CHEAPER TELEGRAMS IN AUSTRALIA.—A number of gentlemen interested in the various industries of the Northern Territory of South Australia recently met to consider the best means for securing a reduction in the cost of telegrams between Adelaide and Port Darwin. After a brief discussion it was decided to bring the matter before the South Australian Government, and the better to attain this object a memorial was prepared to be presented by a deputation to the Minister for the Northern Territories as soon as representative signatures to it are obtained. The memorial suggests that the charge for the first ten words should be reduced from tenpence to threepence.

THE COST OF TELEGRAMS.—It has been suggested that, as a step in the direction of reducing the cost of telegrams, the Post-Office should allow a message of twenty words, the answer to which is prepaid, to be sent for 1s. 6d. The idea is likely to be brought under the notice of the Postmaster-General on an early day.

THE TELEPHONE.—From Birmingham we learn of a new and useful application of the telephone. Between the offices of the Health Department and the borough hospital, three miles distant, telephone communication has been established, in order to lessen the risk of the spread of infection by friends visiting the patients. This method of ascertaining the progress of the hospital inmates is extensively taken advantage of daily.

THE LONDON AND GLOBE TELEPHONE AND MAINTENANCE COMPANY.—This company has been promoted for the purpose of acquiring the telephonic inventions of Prof. Dolbear for a transmitter and receiver (the latter being already well known), and the microphone transmitter of Mr. Anders, together with switch boards, signal bells, and batteries. Included also in the purchase-money (£40,000 in cash, and £90,000 in fully paid shares of the company) is the celebrated "Hunnings" transmitter. No sooner is the prospectus issued than the United Telephone Company informs intending investors through the medium of the press that proceedings will be taken against the new company, the United Telephone Company being advised that the Dolbear, Anders, and Hunnings transmitters are all infringements of the Edison patents. The London and Globe Telephone Company, in response, invite the public to disregard the opposition of the monopolising company. We consider the new company ill advised in bringing forward the last-named transmitter (if they had others equally good), and we hope that the action taken by the United Telephone Company will not have the effect anticipated.

THE NEW ATLANTIC CABLE ENTERPRISES.—In the Senate of the United States, on June 26th, 1882, Mr. Gorman asked and, by unanimous consent, obtained leave to bring in the following bill, which was read twice and referred to the Committee on Foreign Relations. On June 27th, 1882, it was reported by Mr. Windom with amendments, viz., to insert the parts printed in *italics* :—

A BILL

To encourage and promote telegraphic communication between America and Europe.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That Robert Garrett, William F. Burns, and William F. Frick, of Maryland, their associates, successors, and assigns, shall have the right to construct, lay, land, and maintain a line or lines of telegraph or submarine cables on the Atlantic coast of the United States of America, to connect the American and European coasts by telegraphic lines, wires, or submarine cables: *Provided, That said company shall begin to lay said cable or cables within one year from the passage of this Act: And provided further*, That no amalgamation, union, or sale of cable interests established under this Act shall be made to any existing European or other cable companies.

SEC. 2. That any telegraphic line or cable laid be subject to the following conditions, stipulations, and reservations, to wit:

First. The Government of the United States shall be entitled to exercise and enjoy the same or similar privileges with regard to the

control and use of such line or lines, or cable or cables, as there may by law, agreement, or otherwise be exercised and enjoyed by any foreign government whatever.

Secondly. Citizens of the United States shall enjoy the same privileges as to the payment of rates for the transmission of messages as are enjoyed by the citizens of the most favoured nations.

Thirdly. The transmission of despatches shall be made in he following order; First, despatches of state, under such regulations as may be agreed upon by the governments interested, the rates not to exceed those charged to individuals; secondly, despatches on telegraphic service; and thirdly, private despatches.

Fourthly. The lines of any such cables shall be kept open to the public for the daily transmission of market and commercial reports and intelligence, and all messages, despatches, and communications shall be forwarded in the order in which they are received, except as hereinbefore provided.

Fifthly. Before extending and establishing any such line or lines, or cable or cables, in or over any waters, reefs, islands, shores, and lands within the jurisdiction of the United States, a written acceptance of the terms and conditions imposed by this Act shall be filed in the office of the Secretary of State by the parties above named, or a majority of them, their associates, successors, or assigns, or by the company or corporation which may be organised to construct and operate cables under this Act.

Sec. 3. *That nothing in this Act shall be construed to limit the United States in granting to other persons or companies similar privileges herein contained.*

Sec. 4. *That the right to alter, amend, or repeal this Act at any time is hereby reserved to Congress.*

The *Baltimore Sun*, of July 24th, in alluding to the company promoting the above bill gives a somewhat lengthy sketch of the Baltimore and Ohio telegraphs, and also has an article on the subject of the Baltimore and Ohio Telegraphic Cable Company, from which we extract the following :—

The Baltimore and Ohio Telegraph Company announces a list of 535 points in the United States and 33 in the Dominion of Canada which are reached by its own and connecting lines. The places thus reached are in Kansas, Missouri, Wisconsin, Minnesota, Michigan, Illinois, Indiana, Kentucky, Ohio, West Virginia, Virginia, Maryland, District of Columbia, Delaware, New Jersey, Pennsylvania, New York, New Hampshire, Rhode Island, Vermont, Massachusetts, Connecticut, Maine, and Canada. The States through or into which the Baltimore and Ohio Company's own lines extend are Missouri, Illinois, Indiana, Ohio, Kentucky, West Virginia, Virginia, District of Columbia, Maryland, Delaware, New Jersey, and Pennsylvania. The principal cities thus placed in communication with Baltimore are St. Louis, Chicago, Louisville, Cincinnati, Columbus, Sandusky, Pittsburg, and Washington, &c.

The announcement was made on Saturday that the Baltimore and Ohio was preparing to build its own line from Baltimore to New York, and it was stated in official circles that the company would have its own wires through to New York in a very few months. The line is being built through New Jersey this way, from the New York end, and operations will soon begin on the Baltimore end. The Baltimore and Ohio already controls the wire to New York, and when their own is finished will have a through wire from New York to St. Louis. . . . . . In the year 1879 a bill was introduced in Congress to permit railroad companies to do a general telegraph business, most of the railroads having erected their own lines and made contracts of various kinds with the telegraph companies.

This bill anticipated and provided a way for the designs of the railroad companies to form among themselves an opposition to the Western Union Telegraph Company. The Baltimore and Ohio lines formed a very important factor in the American Union system, but their value was only partially acknowledged by the Western Union management. When a new contract was prepared by the Western Union and Baltimore and Ohio for future harmonious operations, certain features of it were objectionable to the Baltimore and Ohio. The Western Union refused to modify it, and the Baltimore and Ohio declined to accept it, and from that time the Baltimore and Ohio has been pushing its own lines with the view of forming the only thorough opposition to the Western Union system.

Following this closely came the announcement that the Baltimore and Ohio was preparing to lay an independent cable between Europe and America, the western end of which will most likely be landed on the Maryland shore. But should the Chesapeake and Delaware canal project succeed it will most likely be landed at Lewes, Delaware, or whatever point is selected as the outlet of the canal. In telegraph circles, however, it is believed that the new cable will be landed in New York, in spite of the announcement that it would probably be landed in Maryland. It is stated that nothing definite will be done in the cable matter until the fall, upon the return of Mr. Robert Garrett from Europe, where he has gone to consult with the European capitalists interested in the undertaking. The cable can be manufactured either in England or in New York, and when completed it is claimed that a steamer like the *Faraday* can lay it in about a month, with favourable weather. When laid it will furnish the only opposition to the present consolidated cable company, whose rates were recently advanced from 25 to 50 cents a word.

Scott's Elevated Wireway.—According to the *Electrician* of New York, this invention consists of a system of housetop cupolas, one on each block, connected with each other by rigid or flexible waterproof tubes, through which common paraffined office wire (say number 18 or 20) can be drawn at will.

Each cupola has a tube connecting it with each of its four neighbouring cupolas. Every block is thus connected with the neighbouring blocks, and through them with every other block in the system, and a wire can be run from any cupola to any other without leaving the tubes.

The wires coming into the cupolas from the tubes are led to cheap connecting screws, where they are connected with those going out through the other tubes. Any wire can, therefore, be interchanged or "patched" if it is found faulty in any section. Wherever a tube crosses a street it is supported by a strong wire that will prevent it sagging. The tubes can be safely stowed away on the housetops without interfering with the comfort of the tenants, and will not be nearly so much in the way as the wires now are.

The paraffined wires may be drawn through the tubes from one cupola to another, either singly or in groups of ten or more at a time, as may be most convenient. Wires lying loosely in this way are affected less by induction than when they all run exactly parallel, as in a cable.

In establishing a new line in a system of this kind the wire is led from its starting point, through the various tubes and cupolas, in the most convenient direction, till it reaches the cupola of the block where it terminates; it is then led from its connecting screw, out at the top of the cupola, through an insulated block, and thence to the roof of the building it must enter.

High Electrical Science at the Academy of Sciences.—The *Comptes Rendus* of the Academy of Sciences of Paris for July 31st contain a somewhat interesting communication, the title of which is in itself a revelation. M. Yves Machai has contributed a note on "Some Theorems of Electricity Inaccurately Demonstrated in Works of Instruction." In this note the writer asserts that errors occur not only in the demonstration but also in the result of a theorem given by M. Mascart in his "Lessons on Electricity and Magnetism," a theorem which establishes a relation between the electric potential at a certain point and the surfaces on a level with it. M. Machai also discusses the demonstration of a theorem given by Clerk Maxwell and the accuracy of a theorem of Earnshaw considered correct by Clerk Maxwell and M. Mascart. M. Machai's conclusion is as follows :—"I could point out other similar instances, but I think I have shown sufficiently by the above examples what attention should be given to the reading of works by even eminent scientific men." The accusation made by M. Machai against the Academy of Sciences is a serious one, and it is not for us to decide upon its truth. It is probable that the question is not at an end, and that M. Mascart will reply. We shall not fail to follow it up.

Dangers from Lightning at Sea and on Land.—There is no reason whatever, says the *Colonies and India*, why every prominent building should not be supplied with one or more perfectly constructed lightning-conductors; and there does not seem to be any reason why ships at sea should not be similarly protected. An iron vessel, and particularly a steamer, which is practically a huge magnet, is especially liable to be struck by lightning, offering as it does a prominent "mark" on the waste of waters; and the accounts which we receive from time to time of ships being struck by lightning at sea suggest a very possible cause of those mysterious disappearances of ships which every now and then are reported. Possibly the cost of lightning-conductors is higher than the average risk of a house justifies the builder in incurring, but if the demand were larger the price would no doubt be reduced.

"The Bewildering Higgs."—This is the title of a smartly-written article in the *New York Times* of June 16th, concerning the peccadilloes of a gentleman formerly resident in London and in the employ of Messrs. Siemens Brothers. It will be remembered that this firm parted with him in consequence of very suspicious circumstances and after legal proceedings against him had been taken. We purpose dealing with this matter more fully in our next.

City and Guilds of London Technological Examinations.—We have received the following list of students

who were successful in the examination in electrical engineering at the above examinations. They were all educated at the College of Science and Arts, Glasgow. We may mention that the total number of successes for the kingdom in electric lighting was twenty-seven. (*See* ELECTRICAL REVIEW for 5th of August.)

(I certify that the following is correct.

JOHN M. M'CURRICH,
Hon. Sec. Science Classes, College of Science and Arts.)

Mr. James Livingston is one of the four taking 1st class in honours, and Mr. Crawford is third in the ordinary stage for electric lighting, and gains the bronze medal.

ON PERRY'S AND AYRTON'S METALLIC GALVANIC BATTERY.—By B. J. Goossens.—According to Perry and Ayrton, a galvanic combination may be obtained by plunging plates of platinum and magnesium into mercury. According to them, this is not the case if other metals, *e.g.*, zinc, are used, because the impurity and great conductivity of zinc, combined with the great liquidity of the amalgam, cause the energy available for the production of a current from the zinc to the non-amalgamable metal to be extremely small. The magnesium amalgam is solid, and the above-mentioned physicists obtained with this element a maximum electromotive force of 1·56 volts. = about 1·5 Daniell as measured with the electrometer.

The experiments of Obach (*Pogg. Ann.*, Ergänzungsband, 1876, p. 300) are in complete contradiction with this result; currents are, indeed, obtained also on the amalgamation of zinc, but these are true thermic currents, which owe their origin to the changes of temperature depending on amalgamation.

Obach, however, did not experiment with magnesium, and, as the subject is of great theoretical importance, the author resolved to repeat the experiments with this metal.

For measuring the current he employed a Thomson mirror-galvanometer, which, with an iron-copper element and slight resistance, gave an indication of 25° of its scale for a change of temperature of 0·1° C.

The mercury was purified with diluted nitric and concentrated sulphuric acid, and was afterwards repeatedly washed with distilled water and carefully dried.

This mercury was placed in a U tube fitted with an enlargement at the top on either side, for the reception of a small plate of platinum, and on the opposite side one of magnesium. The platinum was left permanently in the mercury, and the magnesium was fixed in a wooden slide, by which it could be let down into the mercury. Into the wide parts of the tube there were plunged near, respectively, to the platinum and the magnesium two soldered points of a thermo element, in order to permit the course of the changes of temperature to be observed. The thermo element consisted of an iron wire, to the end of which were soldered copper wires, and it was insulated from the mercury by a coating of lac-varnish.

In order to eliminate possible changes of temperature from external influences, the glass tube was folded round with cotton and placed in a wooden box, and all the points of contact were likewise wrapped in cotton. The experiments were performed in a room not artificially heated. The copper connection wires, coated with silk, were led to a mercury tilt, in order to convey the current of the magnesium-mercury-iron element and of the thermo element through the galvanometer in rapid succession.

As soon as the thermo-element indicated no current and the mercury in both limbs of the tube indicated, consequently, the same temperature, the magnesium was let down into the mercury.

The first deviation of the needle of the galvanometer was not always in the same direction, which may be due to a slight difference of temperature between the magnesium and the mercury. In a few minutes the deviation was always in the same direction, indicating a current from the mercury to the magnesium, consequently a heating current (Wiedemann's "Galvanismus," I. p. 810) increasing rapidly at first, then remaining for a length of time almost constant, and finally decreasing a little. The thermo-element indicated at the same time a heating of the mercury near the magnesium, and its current showed the same changes as the other.

The values obtained in the numerous experiments were not all of equal magnitude, but were all in the same direction. A single example will suffice to show the cause of the experiments:—

Galvanometer Deviations.

Magn. El.......	10	20	40	45	60	80	100
Therm. El.......	100	160	200	240	280	320	370

Half an hour later :—

Magn. El.......250. Therm. El.......700.

From the direction of the current and from the observed rise of temperature, it may be concluded that the current obtained on the amalgamation of magnesium as well as Obach's amalgamation currents is a true thermic current, and has its cause in the rise of temperature accompanying the formation of the magnesium amalgam.

If magnesium and platinum are placed in one vessel near each other a current is observed which at first quickly increases, but then again decreases in consequence of the progressive heating of the platinum, and because magnesium has a place intermediate between mercury and platinum in the thermo electric series.

The following deviations of the needle were obtained at successive intervals of a quarter of an hour : 10, 120, 120, 100, 80.—*Wiedemann's Annalen.*

ON LIGHTNING CONDUCTORS.—By M. Melsens.—I propose to reply on a future occasion in a complete manner to the various objections raised against my system of lightning conductors. I will, in particular, discuss the opinion which sees danger in the use of a sort of cage formed of multiple conductors, among which some persons seem to fear the production of sparks of electrostatic induction. I will merely for the present recall an experiment which seems to me decisive, and which has been thus regarded by many physicists. This experiment supports those of Faraday, which prove that no electric manifestation is possible in a cage with continuous metallic sides, or of metallic network placed in perfect communication with one common reservoir.

Any small animal, such as a rabbit, &c., is placed in a hollow globe of metallic network placed upon the coating, or suspended from a powerful Leyden battery. The attempt was then made to strike the animal by the discharge. But far from being struck down the animal did not experience any action from a spark which would have been dangerous or even mortal but for the protection of the metallic cage.

The cage represents my lightning conductor, and the animal enclosed represents a house with its inhabitants, and the combustible matter which it may contain. I remark, further, that my conductor is fitted with numerous points, which certainly have not the property of provoking electric manifestations in the interior of a metallic cage, especially if it is in perfect connection with the moist earth, or with large metallic surfaces, or in a town with the water and gas pipes.—*Comptes Rendus.*

"On Singing Condensers."—By W. Holtz.—In view of the attention which has been latterly given to the so-called singing condensers, I remark that as far back as 1875 (*Annalen*, 1875, p. 496), I made mention of a similar phenomenon, which, however, remained unnoticed. I observed it in hollow metallic discs, which I used as the electrodes of an influence machine, on bringing them so near that sparks struck across between them. I remarked then that on gradual approximation the tone did not become continually, higher but occasionally ceased entirely, because the dimension of the disc could not correspond to every height of tone, and that this is the best proof that the sound in question is not merely the sound of discharges, which may be also proved by transferring the latter to a distance. Whoever wishes to repeat the experiment, for which a single disc suffices, placed opposite a large globe, will proceed most correctly, in order to vary the approximation and the length of sparks independently of each other, if he allows the sparks to strike from one discharging rod to one of the sliding cylinders of the well-known intercalatory apparatus. With a certain succession of sparks and at a certain approximation the disc sings more distinctly, but it can sing at very different heights. Generally we hear simultaneously several and indeed disharmonic tones, such as may be heard in vibrating plates. Leyden jars must be first removed.—*Wiedemann's Annalen.*

On Double Refraction in Glass and Sulphuret of Carbon occasioned by Electric Influence.—By H. Brongersma.—The author has re-examined the phenomena first observed and described by Kerr in his memoirs on "A New Relation between Electricity and Light" (*Phil. Mag.*, 1875, p. 337), chiefly because certain physicists have failed to obtain the same phenomena as far as solid bodies are concerned. He found, however, that the doubts as to the correctness of Kerr's results are unfounded. If explanations based upon the supposition that electricity produces these phenomena in an indirect manner are not confirmed by an experimental examination, it becomes more and more probable that we have here to do with a hitherto unknown action of electricity upon the luminous vibrations.—*Wiedemann's Annalen.*

A Galvanic Element.—By Kuhlo.—The earthenware cylinder of a Daniell's element is replaced by a tube of parchment paper, which is fixed by means of india-rubber rings to a cylindrical frame of an insulating material consisting of a bottom plate and superimposed rods, connected above.—*Electrotechn. Zeitschrift.*

Chromic Acid Elements.—The zinc plate is laid on the bottom of the cell, or preferably zinc amalgam is put into a shallow beaker, as the solutions of chrome, alum, and sulphate of zinc, being heavier, sink to the bottom and do not attack the zinc.—*Wiedemann's Beiblätter.*

NEW COMPANY REGISTERED.

Patent Electric Gas Igniting Company (Limited).—Capital £100,000 in £5 shares. Objects:—To manufacture Clarke's patent electric lamp and apparatus and appliances for the lighting of gas by electricity or for the generation, accumulation, or transmission of electricity either as a motor, igniting or lighting power; also to acquire the properties and liabilities of the Electric Gas Lighting Company (Limited) and of the London and Provincial Electric Gas Lighting Company (Limited). Signatories (with one share each): Sir R. W. Rawson, 68, Cromwell Gardens; Francis Bennoch, F.S.A., 5, Tavistock Square; S. F. Porter, Putney; J. Leigh and William Milne, Alderley Edge, Cheshire; J. H. Stretton, 2, Dean Street, Park Lane; J. A. Hilliard, Grove Park, Kent. The signatories are to appoint the first directors. Remuneration: Chairman, £300 per annum; deputy chairman, £200 per annum; ordinary directors, £150 per annum each. The members of the board will also be entitled to a commission of 1 per cent. upon the amounts received from the sale of foreign patents, and after 2½ per cent. of the net profits remaining after payment of 10 per cent. to the shareholders. Registered 2nd inst. by Newman & Co., 75, Cornhill.

NEW PATENTS—1882.

3698. "Micro-telephonic apparatus." J. H. Johnson. (Communicated by A. D'Arsonval.) Dated August 3.

3700. "Secondary batteries." E. G. Brewer. (Communicated by O. Schulz.) Dated August 3.

3705. "An improved construction of electric lamp." J. L. Somoff. Dated August 4.

3710. "Improvements in electric lighting and in apparatus connected therewith." T. Parker and P. B. Elwell. Dated August 4.

3712. "Construction and arrangement of the cores and armatures and other parts of electro-magnets." S. C. C. Currie. Dated August 4.

3713. "Electric arc lamps." E. G. Brewer. (Communicated by Société Anonyme des Ateliers de Construction Mécanique et d'Appareils Electriques.) Dated August 4.

3751. "Electrical signalling apparatus for railway or other purposes." W. R. Lake. (Communicated by G. W. and A. D. Blodgett.) Dated August 5.

3752. "Means employed in or for transmitting electricity for light, power and other purposes." T. J. Handford. (Communicated by T. A. Edison.) Dated August 5.

3753. "An improved combined holder and switch for incandescent electric lamps." C. E. Sibley. Dated August 5.

3755. "Electrical meters." T. J. Handford. (Communicated by T. A. Edison.) Dated August 5.

3756. "Dynamo or magneto-electric machines." T. J. Handford. (Communicated by T. A. Edison.) Dated August 5.

3757. "Improvements in the manufacture of light emitting conductors for electric lighting purposes and in apparatus therefor, which apparatus is also applicable for other purposes." R. Werdermann. Dated August 5.

3762. "Apparatus for utilising the force of fluids, air, and water (producing electric currents)." E. E. H. Rousseau. Dated August 8. (*Complete.*)

3763. "Telephones." J. J. Barrier and F. F. de Laverrède. Dated August 8.

3770. "Preparation of lead for use in the cells of secondary batteries." L. Epstein. Dated August 8.

ABSTRACTS OF PUBLISHED SPECIFICATIONS, 1881.

5286. "Production of the electric light, &c." A. R. Sennett. Dated December 3. 6d. Has for its object improvements relating to the production of the electric light, more especially with reference to that system in which it is obtained by the incandescence of a continuous conductor enclosed in a vacuous receiver. Firstly, in the preparation and production of a conductor more uniform in its specific electrical resistance, and better adapted to withstand the very high temperature to which it must necessarily be subjected, and to the disintegrating action of the residual gas of the receiver. Secondly, in the method of compressing and compacting the same so as to render it extremely dense and imporous. Thirdly, in the method of carbonising the same. Fourthly, in the method of mounting the same. Fifthly, in the method of eliminating the atmospheric air from the receiver. Sixthly, in the method of making the joint between the material of the receiver and of the conductors. To obtain these objects the inventor reduces any material sufficiently pure, and containing a high percentage of cellulose, to a finely divided, jelly-like state or pulp (either fibrous or otherwise) by chemicals, or other means. In this condition the whole of the impurities so detrimental to the durability of the conductor can most conveniently be removed by the usual chemical means; from this are formed by moulding, or other operation, the required conductors. In order to produce the requisite hardness and compactness, the inventor moulds or forms the conductor under great pressure, whilst to insure its imporosity this operation is caused to take place (very slowly) in a vessel from which the air is being constantly exhausted.

5367. "Machine for coating insulated electrical conductors with lead." W. R. Lake. (A communication from abroad by Hiram Stevens Maxin, of Brooklyn, America.) Dated December 8. 6d. Relates to a machine for covering insulated wires with lead. (*Provisional only.*)

5396. "Electric lamps." C. F. Varley and F. H. Varley. Dated December 9. 6d. Consists mainly as follows:—A hollow cylinder of sufficient length to hold the carbon rod is provided with a spiral spring or propelling weight, for the purpose of feeding the carbons. At or near the feeding end or cap of the cylinder is a roller contact-clutch, which is made to be adaptable for varying diameters of carbon rod, and through which the current is conveyed to the carbons. In one arrangement an insulated swing arm is used, fixed into the cap, which carries a fixed opposite carbon pole. To charge this lamp the swing arm is moved on one side. The carbon rod or candle is inserted through the roller contact-clutch, and forced into the socket attached to the lower, or remote end, of the spiral spring, and this forces back the spring to the length of the carbon to be used. The roller clutch is provided with a magnetic regulator, for determining the length of the arc.

5524. "Electric lamps, &c." Rankin Kennedy. Dated December 17. 8d. Relates to both incandescent and arc electric lamps, and its objects are principally to facilitate the manufacture, to render

certain parts or connections more satisfactory and durable than as hitherto made, and to obtain an improved automatic regulation. Figs. 1 and 2 show the improvements in arc lamps in which the length of the arc and the movements of the carbons are regulated by means of the lamp current passing through the solenoid, *a*, as shown, thereby acting magnetically, as is well understood, upon the core, *c*, which is connected to the crossbar, *d*. This crossbar, *d*, carries at its ends the pawls, *e*, *e*, and is at the same place coupled to the pawl levers, *f*, *f*, by pins, *n*, *n*, which pass through holes in the crossbar, *d*, pawls, *e*, *e*, and pawl levers, *f*, *f*, the latter being mounted at their outer ends upon the axes, *g*, *g*, which also carry the ratchet pulleys, *h*, *h*. The upper carbon is attached to the core, *c*, of the solenoid, *a*; and the lower carbon, D, is attached to the carbon holder, B, which is suspended by cords, *i*, *i*, passing over the ratchet pulleys, *h*, *h*, and is kept in proper working position by the antifriction rollers, *k*, *k*,

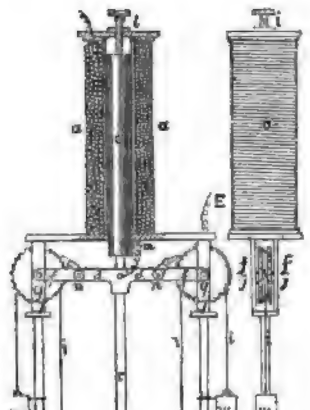

FIG. 1. FIG. 2.

bearing against the upright bars of the framing, *j*. When the lamp is put into circuit the current passes through the solenoid, *a*, thence through the wire, *m*, to the upper carbon, C, and from this the current passes across a space occupied by the arc to the lower carbon, D, which is not insulated from its carrier, thence to the return wire, E, through the metallic connections formed by the rollers, *k*, *k*, and the framing, *j*. When the current passing through the solenoid, *a*, is of less than the proper strength, the solenoid core, *c*, descends, and at the same time releases the pulleys, *h*, *h*, so that the carrier, B, and the lower carbon, D, rise, while at the same time the upper carbon descends. This shortens the arc, and allows a greater quantity of current to pass; the solenoid then draws up the core, *c*, and thus checks the pulleys, *h*, *h*. An adjustable screw stop, *l*, is fitted at the upper end of the solenoid, *a*, so that the raising action of the core is limited to give the precise length of the arc described.

5577. "Electric telegraphs." SIR JAMES ANDERSON and BENJAMIN SMITH. Dated December 20. 6d. Has for its object improvements in electric telegraphs, and relates more especially to the means of and apparatus for retransmitting or "translating" telegrams from one telegraph cable or telegraph line to another. The improvements render fewer the operators to be employed and expedite the transmission of telegrams.

According to this invention one set of instruments can be employed, one key and one recorder for the two cables, and for this purpose the inventors employ a novel switch having a lever handle which has three positions. In the central position of the handle both cables (or the condensers into which the cables work, if such be employed, as is usual) are connected through the recorder to earth, and in this position a call signal sent through either cable is received upon the paper of the recorder. When the handle is moved to either side one cable remains connected with the recorder, whilst the other becomes connected with the key and through the key with the battery. The operator then on receiving a call moves the handle over from the central position to that side which leaves the calling station connected with the recorder, and as the telegram comes in he reads it from the paper of the recorder and retransmits it by means of the key into the other cable. When the handle of the switch is moved over to the other side the connections are reversed and become suitable for working in the opposite direction through the cables. The same movement of the handle alters the battery from what is suitable for one cable to that which the other cable requires.

5601. "Electrical brushes and combs." J. N. ARONSON. Dated December 21. 6d. Relates to electrical brushes and combs for the application of currents of electricity to the skin of the head and roots of the hair, for promoting the growth of the hair and for curative and remedial purposes. The invention relates to the combination with a brush or comb constructed for the transmission of electric currents to the skin and roots of the hair, of an induction coil and battery for the generation of the currents, and to the peculiar construction of the brush and comb for the purposes above mentioned.

5618. "Holder for incandescent electric lights." DAVID GRAHAM. Dated December 22. 6d. Relates to a new or improved holder for incandescent electric lights, and consists of a piece of insulating material, in the one end of which a screw thread is cut, or a screwed bush may be placed thereon, in order to attach the holder on to the screw of an ordinary burner socket of a gas bracket or gasalier. This block or plate of insulating material has placed on it a spring, or elastic socket, for holding the parallel or tubular part of the glass chamber of an incandescent light. The spring, or elastic holder, is made in two portions, insulated from each other. Into each portion a pinching screw passes, which, when the lamp is placed in its socket, bear upon the two metallic tongues leading and joined to the platinum or other wires to which the carbon is joined. Thus these pinching screws form electrical connection between the outside metallic portions of the holder and the interior of the lamp, so that by their means when a current is passed through the holder it is transmitted by the pinching screws to the lamp conductors. The holder may be provided with a switch or an equivalent apparatus for making and breaking contact. Electrical connection with the light holder is made by passing the wires of a circuit by preference, for the sake of convenience and neatness, through the tube of a gas bracket or gasalier out through openings formed in the side of the nozzle or gas burner socket, these wires being insulated from the metal of the socket.

5639. "Electrical alarm apparatus for railway trains." DOTTORE SALVATORE GARAU. Dated December 23. 6d. Has for its object improvements in electrical alarm apparatus for railway trains, to enable passengers to give an alarm to the guard or driver in case of necessity. For this purpose the inventor provides at each end of each carriage of a railway train, in addition to its ordinary buffers, two other insulated metallic buffers pressed outwards by springs to a distance somewhat exceeding that to which the ordinary buffers are pressed out, so that when a train is made up the metallic insulated buffers are of necessity brought into contact with one another. The insulated buffer at one end of each carriage is coupled by an insulated wire with one of the buffers at the opposite end of the carriage, and similarly couple together the other two buffers. At any desired number of points at the sides and ends of the carriages are affixed a series of contact apparatus so constructed that by the pulling out or pushing in of a stop an electrical contact may be established between the two terminals of a contact apparatus to which the stop belongs. One of the terminals of each contact apparatus is connected by a wire with one of the wires connecting two of the insulated buffers, and the other terminal with the other wires connecting the two other buffers.

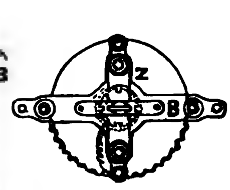
5651. "Electric current meters." ST. GEORGE LANE FOX. Dated December 24. 6d. Has reference to improvements in electric-current meters, and especially to that class of apparatus described in the specification of former letters patent granted and dated November 14, 1878, No. 4626, in which apparatus the position or motion of an armature due to the amount of current passing through a corresponding electro-magnet, controls the working of the clockwork or mechanism of a counting apparatus. One part of this invention consists in the employment of a magneto-electric motor to give a constant motion to a certain shaft in the meter—the inventor uses a horizontal shaft free to oscillate about a vertical axis passing through its centre; at the ends of this shaft are placed two armatures, each opposite an electro-magnet; or there may be only one armature and a corresponding electro-magnet. It is arranged that these magnets (when there are two) are put into action alternately by springs which make contact according to the position of the shaft, and by properly balancing and weighting the shaft perfectly regular oscillations are obtained. An auxiliary spring is employed in connection with the shaft so as to insure one of the connections being made when the instrument is at rest, so that it may start directly any current flows.

5656. "Apparatus for working electric clocks, &c." E. G. BREWER. (A communication from abroad by C. E. Buell, of America.) Dated December 24. 8d. The object of the first part of this invention is to dispense with the use of local batteries as ordinarily used at the sub-stations of a line used for controlling electric clocks, and to this end is devised a certain combination of a relay in a constantly closed main-line circuit with a secondary battery in a derived circuit, together with a clock to be operated by the battery in such circuit, the whole being combined with an electro-magnetic switch controlled by the relay in the main-line circuit in such a way that in one position of the switch the secondary battery is charged by the current flowing through the main-line, while in the other position of the switch the derived current from the main-line is broken, and the current of the secondary battery is closed locally through the operating or controlling electro-magnet of the electric clock. By this combination of apparatus the clock can be operated with certainty and at the same time dispense with the use of local galvanic batteries ordinarily employed in conjunction with relays in the main-line circuit. The object of the second part of this invention is to operate fire-alarm signal apparatus upon the same circuit with electric clock apparatus in such a way that the operation of signalling by the fire-alarm devices shall not interfere with the correct transmission of the impulses which control the clocks, while *vice versâ* the operation of controlling the clocks at sub-stations from the standard clock at a central or terminal station shall not at any time prevent the transmission of the fire-alarm signals. The object of the third part of the invention is to so combine the apparatus for sending the controlling impulses for electric clocks, and telephone indicating and signalling apparatus, that the two systems may be used upon the same line without interference with one another.

5660. "Electric lamps." L. S. POWELL. (A communication from abroad by J. M. A. Gérard-Lescuyer, of Paris.) Dated December

24. 6d. Relates to electric lamps and it consists in certain improvements in the construction and arrangement with the apparatus for automatically operating and regulating the feed of the carbons employed to produce the voltaic arc as hereinafter described. Figs. 1, 2, 3, and 4 represent a lamp worked by alternate currents to which the invention is applied, the said figures representing respectively a vertical section, a side elevation, a plan, and a horizontal section of the said lamp. This apparatus operates as follows:—Before lighting the lamp the carbons are separated, so that the current being unable to pass along the carbons is entirely diverted into the shunt or coil of the electro-magnet, which thus becomes excited and attracts the two armatures, O and T. The attraction exerted on the upper armature, T, has the effect of drawing down the short vertical rods, S, and thus opens the claws, U, causing them to release the upper carbon holder, which thereupon slips down very slowly, its descent being retarded by

Fig. 3.



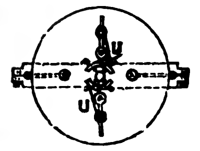


Fig. 4.

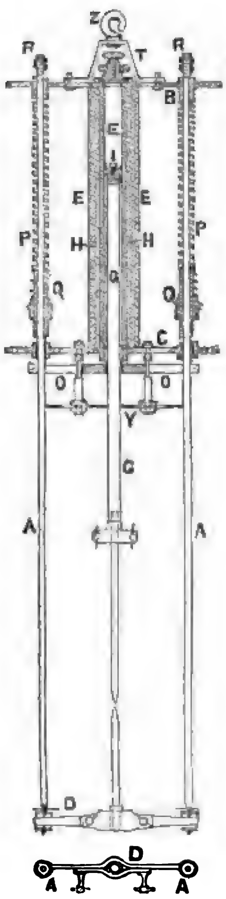

Fig. 1.

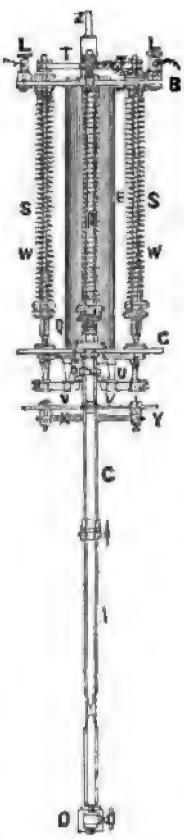

Fig. 2.

the partial vacuum produced behind the piston, I. The rate at which the carbon descends may thus be controlled by adjusting, by means of the valve, the rate at which air is allowed to pass into the tube, F, above the said piston, I. The lower armature, O, is also attracted by the electro-magnet at the same time that the upper armature is attracted and in such a manner as to draw up the rods, A, connected with the lower carbon holder, D. When the carbons are brought into contact the current passes through them almost exclusively, so that the electro-magnet, E, is demagnetised. The armature, T, connected by the rods, S, with the claws of the brake is then raised by the helical springs, W, around the said rods, and the claws, U, again clasp the upper carbon holder, whilst at the same time the lower carbon holder is also released and allowed to drop by its own weight for a distance regulated by the nuts or stops, B, on the rods, A, thus establishing the arc. When the resistance at the arc becomes excessive the power of the current in the coil of the electro-magnet, E, is increased, whereupon the armatures are again attracted and the carbons are brought together as hereinbefore described.

5661. "Pipes for containing electrical conductors." J. H. Johnson. (A communication from abroad by Clément Labye and Léon de Locht-Labye, both of Paris.) Dated December 24. 6d. Relates to pipes or conduits for containing electrical conductors or wires, and it consists of an improved method of arranging and enclosing the said conductors or wires in a conduit or chamber constructed with a removable cover. This conduit is first placed in position in the ground, after which the wires are arranged in its interior in layers being imbedded in asphalte or other suitable insulating material, are further protected from injury by a cover which is subsequently attached to the conduit. (*Provisional only.*)

5665. "Apparatus for producing and regulating electric light, &c." S. A. Varley. Dated December 24. 10d. Has for its object ents in apparatus for producing and regulating electric roducing electric light it is desirable the electricity pro- ld be as nearly as possible of uniform potential, and there- he light circuit should be of as nearly as practicable constant fault common to dynamo-electric machines is that the electricity developed by them even under favourable conditions is of a more or less undulating potential. Now by the present invention this defect is reduced and the electricity developed is made to automatically regulate its production and also to regulate the resistance of the light circuit. To this end the inventor constructs a number of wheels which he terms the "armature wheels;" the periphery of each of these wheels consists of an even number of iron blocks magnetically insulated from one another, which blocks are called the "bobbin armatures." These armatures are grooved out in the centre to receive the bobbin magnets and when completed present a nearly continuous surface of iron to the field magnets. B (fig. 1) represents one of the armature wheels; its periphery consists of an even number of blocks of iron, A, having notches or grooves, A×, cut in them. These blocks are magnetically insulated from one another by the teeth or projections, A^2, and are mounted on the wheel, B, which is constructed of a suitable non-magnetic metal, to which they (the blocks) are brazed, or soldered, or attached by other suitable means. These armature wheels are mounted, at equal distances from one another, on the axle, A××, of the machine, as shown in fig. 2. Soft iron bobbin magnets, C, wrapped with coils or bobbins of insulated wire, C, fit into the notches of the blocks of iron, A. The armature wheels are mounted on an axle at equal distances from one another, the recesses in the armature blocks being arranged in a line with the axle, the bobbin magnets fit into these recesses, and it is preferred to construct them of a number of thin plates of iron arranged side by side magnetically insulated from one another by pieces of paper or other suitable insulating material placed between the plates. Fig. 3 is a front view, and fig. 4 is an end view of one of the bobbin magnets, C, and one set of bobbins, C^1. The bobbin magnets are wrapped with insulated wire in the spaces between the armature wheels, which

FIG 1

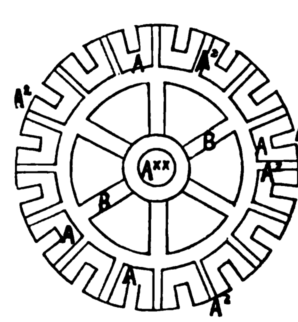

FIG 2

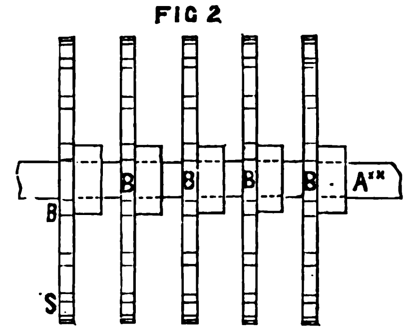

FIG 4 FIG 3

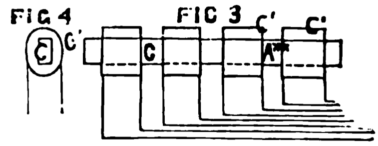

FIG 5

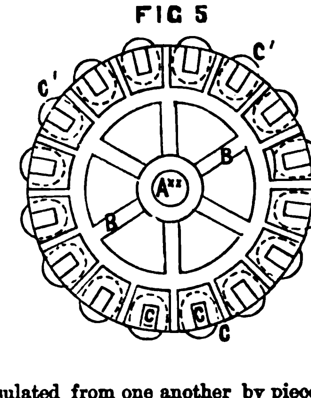

wheels divide them into sections. Fig. 5 is an end view of the armature wheels, with the armature blocks, bobbin magnets, and bobbins mounted in their places.

5667. "Collection and distribution of electric currents." S. A. VARLEY. Dated December 24. 6d. According to this invention the inventor causes the contact poles of the dynamo machines to move in contact with the insulated segments connected to the armature coils with a rolling friction and he imparts to the poles a motion of rotation equal to or slightly greater or slighly less in circumferential velocity than the motion of the insulated segments.

5674. "Transmitting and receiving apparatus for type-printing telegraphs." SYDNEY PITT. (A communication from abroad by Henry Van Hoevenbergh, of America.) Dated December 27. 10d. Relates to type-printing telegraphs in which the type wheels of the receiving instruments are impelled by a weight or spring acting through suitable intermediate wheel-work, and the progressive movements of said type-wheels are controlled by a series of electrical pulsations alternately of opposite polarity, which are transmitted over the main line from the sending station. These pulsations cause the rapid to-and-fro vibration between electro-magnets of an armature, suitably constructed to be actuated by such alternating currents and the vibrating in turn controls the type wheel, by means of a step-by-step escapement, of well-known construction. In the improved apparatus the printing is effected by increasing the strength of the electric current during some one of the pulsations, without reference to its polarity, at the instant the required division or character of the type wheel is opposite the platen, and this action takes place without retarding the progressive movement of the type wheel, or interrupting the regular succession of electric pulsations. The momentary stoppage of the type wheel shaft at the termination of each vibration of the step-by-step escapement affords sufficient time to permit an impression to be taken from the type wheel by means of proper mechanism.

5681. "Construction and arrangement of dynamo-electric machines." J. RICHARDSON. Dated December 27. 4d. Relates mainly to a particular construction and arrangement of armatures in couples or pairs capable of augmentation in connection with field magnets to produce a constant electrical current of uniform intensity. For the purposes of the invention the inventor arranges a series of two armatures at right angles to each other, and so fitted in connection with field magnets that one is at the point of maximum when the other is at the point of minimum intensity, and as one increases in intensity in the same ratio the other diminishes the sum of the two will produce a constant intensity of current. Six pairs of these armatures with their corresponding field magnets are preferably arranged in the same machine, and it is evident that any number from one pair upwards can be used with an augmentation in electricity according to the number used, and that all can be "coupled up" to two contact pieces on the commutator overlapping each other by one-fourth of its circumference, or, if necessary, two commutators could be used and three pairs of armatures coupled to one and three pairs to the other, their axes being at an angle of 45° with the others, if such an arrangement was necessary, to produce still greater uniformity of current. This system of construction and arrangement also possesses the advantage of simplicity of manufacture, a great variety of sizes of machine being possible to be made from the same patterns simply by lengthening the bed plate and coupling together greater numbers. All the winding can be done by machinery, thus economising labour, and the armatures can be coupled together for either quantity or intensity as may be required, also either one or all the pairs can be used to excite the field magnets according to the strength required in them.

5687. "Controlling and regulating the production and distribution of electricity." C. A. CARUS-WILSON. Dated December 27. 8d. Has reference to means or apparatus for controlling and regulating the production and distribution of electricity. One part of the invention consists in a method of acting upon the generating machine, water, steam, gas, or other engine in addition to the ordinary governor; the inventor permits the governor to regulate the motion of the engine in the usual way, but supplements its action so that it regulates the cut off with respect to the electromotive force produced. The manner in which this may be effected is as follows:—The inventor arranges that a force, preferably a weight, shall be brought to bear upon the governor as it rotates, and that this force shall be under the control of two electro-magnets, one to apply the force and another to take it off. These magnets are respectively brought into action by currents whose circuit is made and broken by a galvanometer needle. When the engine is producing the desired electromotive force, the galvanometer needle is stationary between two stops, a short way apart, the weight or other force meanwhile keeping the governor down a little, and when the electromotive force rises the needle is deflected against one of the stops, making circuit through one of the magnets, and this will alter the force on the governor, causing a decrease of speed and hence a decrease of electromotive force. On the other hand, if the electromotive force fall, the needle will touch the other stop, and thereby cause the other magnet to act and the weight or other force to be applied to the governor in the other direction, which will increase the electromotive force.

5702. "Sockets or holders for electric lamps." J. W. SWAN. Dated December 28. 6d. Relates to improvements in sockets or holders for electric lamps, whereby a lamp without any external fittings can be readily attached to the conducting wire and a good contact between them and the terminal hooks or eyes of the lamp can be effected and maintained. In carrying out the invention the holder is provided with two hooks or equivalent devices insulated from each other and terminating in binding screws or contact pieces on opposite sides of the holder or suitably arranged for making concentric contacts by the act of screwing the holder to the lamp bracket or other support for the lamp. In either case contact between the lamp and the lamp socket or holder is effected by engaging the two hooks or their equivalents belonging to the socket with the two eyes or other counterpart devices which constitute the terminal conductors of the lamp. Firm contact between the hooks and the eyes or their equivalents of the lamp and socket is produced by the action of a spring placed in compression or in tension by the act of making the connection between the lamp and its socket or by the act of screwing or sliding towards the lamp an external tube so that an outward pressure may be exerted upon the lamp tending to put the hooks and eyes or their equivalents into tension and thus effecting and maintaining a good electrical contact.

5738. "Electric lamps." J. G. LORRAIN. Dated December 31. 4d. Relates to improvements in incandescent and other electric lamps, and has for its object diffusing the light and economising the same by preventing its radiation in directions where its effects are not required and of concentrating the light in a required direction and also rendering it more pleasant to the eye, and the invention consists in silvering or coating with a reflecting material a portion or portions of the bulb or globe of the lamp in such a manner as to produce the effects before mentioned.

5743. "Electrical resistances." GUSTAV PFANNKUCHE and R. E. DUNSTON. Dated December 31. 6d. Relates to certain improvements in the construction of electrical resistances. On account of the heat developed in the resistance coils or boxes as at present existing these arrangements are exceedingly bulky, unhandy and expensive, and it is obvious that it is possible to use wires or other materials of very high resistance and at the same time make provision for uniformly distributing and carrying away the heat developed in these wires or other materials a very efficient and handy and cheap resistance apparatus can be produced. To effect this the inventors propose to use wires or other suitable materials of high resistance and of a size proportional to the required amount of resistance and to embed or envelop the same in a mass of a bad conductor of electricity, such as glass or plaster of Paris or asbestos, or any other non-conducting mass, shaping the same in such a manner as to get as large as possible a cooling surface and to rapidly take up the heat developed in the resistance wires or other material, and thus preventing the resistance material from being destroyed or fused when a strong current is made to pass through it. It will be seen that in this manner comparatively very small wires or other materials can be used as resistances for large currents, thereby materially reducing the size and expense of such resistance apparatus.

5751. "Operating or controlling railway brakes by electricity." W. R. LAKE. (A communication from abroad by Augustus L. Duwelius, Leonard W. Goss, Paget Higgs, Frank R. Merrell, Hiram D. Peck, and Hugo Walter, all of America.) Dated December 31. 6d. Relates to the application of electricity for operating the brakes of railway trains, and embodies various improvements designed to render the same practicable and efficient. These improvements comprise the following features, that is to say—combining in such a manner as to be under the control of the engine-driver one or more generators of electricity with storage batteries or other electric accumulators and suitable connections with the brake actuating mechanism. A method or system for circuiting the electro-brake mechanism of a train of railway vehicles, consisting in the employment of main conductors attached in separable sections to each vehicle and forming, when connected, substantially continuous electric mains, with permanent cross connections at each vehicle in which the electro mechanism of the brakes is interposed. The construction and arrangement of electro-brake mechanism by which the electro-magnetic force is applied.

CITY NOTES.

OLD BROAD STREET.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).

THE report of the directors ran as follows:—The total receipts from January 1st to June 30th, 1882, including a balance of £4,811 13s. brought over from the last account, amount to £208,750 1s. 7d. The traffic receipts show a decrease, as compared with the corresponding period of last year, of £94,349, consequent upon reduced rates.

The total expenses of the half-year, including income-tax and repair of cables, &c., as shown by the revenue account, amount to £58,166 1s. 10d.

The directors, under the powers conferred upon them by the articles of association, have, before declaring the net profits, set apart the sum of £75,000 to the renewal fund, leaving an available balance of £75,583 19s. 9d.

One quarterly interim dividend of 5s. per cent. on the ordinary stock, and of 10s. per cent. on the preferred stock, free of income-tax, was paid on May 1st, 1882, absorbing £17,500, leaving a balance of £58,083 19s. 9d., from which a second quarterly dividend of 15s. per cent. on the ordinary stock, and of 30s. per cent. on the preferred stock, free of income-tax, will be paid on August 1st, 1882, leaving a balance of £5,583 19s. 9d. to be carried forward to the next account.

The cable laid by this company in 1874 was broken off the coast of Ireland on November 22nd, 1881; it was successfully repaired on February 5th last, and has since worked well.

The Brest-St. Pierre cable, laid in 1869, was broken in mid-ocean on March 18th last. The repairs have been intrusted to the Telegraph Construction and Maintenance Company, and, from the progress already made, the directors hope soon to be able to announce the restoration of communication by that cable.

The company's repairing ss. *Minia* has been engaged during the half-year in repairing the St. Pierre-Duxbury cable, laid in 1869, the Placentia-St. Pierre cable, laid in 1872, and the South Placentia cable, laid in 1873. The company's system of cables and land lines on the other side the Atlantic is now in good working order and condition.

The ordinary general half-yearly meeting of the company was held in the City Terminus Hotel, on Friday, the 4th inst., the Right Hon. Viscount Monck, chairman of the board, presiding.

The Secretary, T. H. Wells, Esq., having read the notice convening the meeting, the minutes of the last ordinary and extraordinary meeting were read, approved, and signed.

The report was taken as read.

The Chairman said: Gentlemen, it will be in your recollection that at our last half-yearly meeting, we were engaged in a competition with a telegraph company, formed in America and known by the name of Mr. Jay-Gould's Company. You are also aware that at an extraordinary meeting, the minutes of which have just been read, held subsequently to that half-yearly meeting, we passed resolutions confirming an agreement with that company, which brings us into a state of harmony with them. Well, gentlemen, I merely allude to that fact, because it prevents us from doing what I generally do at this half-yearly meeting, institute a comparison between the receipts which have accrued to us during the past half-year, with the receipts of the previous half-year. It is obvious that no satisfactory comparison of that kind can be made at present, because the circumstances under which we were operating during the half-year to which I allude were of a nature which renders it impossible to institute any comparison between the receipts. The rate of tariff was entirely different, therefore any comparison between the aggregate receipts of two half-years would be entirely futile and misleading. However, on the 22nd May last, the agreement to which I have alluded having been concluded and ratified on all sides, we recurred to a tariff of two shillings a word, and our experience since our recurrence to the tariff is so far satisfactory. Now, gentlemen, the next topic to which I would draw your attention is as to the expenditure of the half-year. The real expenditure which we can control, of course, is only that of the offices in London and at the stations, and the money laid by to renewal fund. The payment of different expenses connected with the working, independent of the office expenses, are permanent charges, and cannot be very much diminished or increased, but the expenses at the offices admit either of reduction or of increase. It will be satisfactory to you to find that at the head office in London during the last year we have been able to make economies to the extent of £300 a year (laughter). I do not understand the meaning of the laughter. Perhaps you would have rather seen an increase of £300. The different items of expenditure at the central office show an increase of £150 12s. 3d. against a decrease of £474 8s. 3d., showing on the balance a reduced expenditure at the head office of about £325 a year. The expenditure at stations shows a very different result. There the increased expenditure has been about £4,400 a year. Out of this we must deduct a very large expenditure for the provision of new instruments which, of course, became necessary from time to time. We have been obliged to pay £1,000 for new instruments, and we have also been obliged to pay for the use of a patent for the Wheatstone instruments. With reference to this increase of the expenditure at stations, the last time I had the pleasure of addressing you here, I mentionod that, of course, the reduced tariff involves additional work. The only object of reducing the tariff was to increase the number of messages sent, and an increase in messages sent necessarily involves an increase of persons engaged to send them. You cannot do double the work with the same number of people, and that accounts for the increase of expenditure at the stations to which I have alluded. You will find an increase in every item of expenditure which involves the employment of increased number of persons to do your work. There is an increase under salaries and wages of £1,200; an increase in the maintenance of old lines, in stationery, and in lodgings, fuel, and provisions. That accounts for a large portion of the increase in expenditure during the past half-year. We may look for economies in this respect in the future, because as we have raised our tariff we shall not have—of course we are very glad to have it—additional traffic which would cost us more to carry. I am afraid the increased tariff must necessarily reduce the number of words sent and will enable us to make economies in the expenditure. So much for the receipts and the expenditure. I now wish to say one or two words on the subject of the condition of your plant. The lines are all working well. Within the last few months, as you are aware, the Brest-St. Pierre cable, which has been in the water for thirteen years, developed a fault which suspended its operation. During the last winter we have sent an expedition out to repair that cable, and I am happy to be able to tell you that we have been enabled to raise it in very nearly 2,000 fathoms of water. We are not all nautical people in the room, but I may say that 2,000 fathoms means something over 2¼ miles, and we have been enabled to get up that cable which has been thirteen years in the Atlantic, at a depth of 2¼ miles, and repair it. The repairs are not absolutely complete, that is, I cannot tell you that they are, because we have not received a telegram from the ship, though we expect one literally every moment, to say that it is thoroughly repaired and in good condition. In connection with these repairs we have performed a feat which I think is of some importance. We have laid down in the centre of the Atlantic, in connection with this cable about ninety miles of new telegraph cable. That cable is capable of being raised and added to at any moment. It is a matter of as much certainty as picking it up off the floor of this room, if it lay there, and if it were necessary to make further additions to that new cable; so that I apprehend the life of the 1869 cable will, by the operation we have performed lately, be very considerably prolonged (hear, hear). We have also in that same cable a considerable proportion of new cable within 300 miles of Brest, which we have put in. So that you see we are, so to speak, darning that cable as if it were an old stocking, and making it as good, and probably stronger, than it was before. Well, gentlemen, that is our condition. We have had a good deal of competition from time to time to contend against, and I understand that we are threatened with further competition. Well, perhaps if I were to offer advice to persons inclined to invest their money in new telegraph operations I might be considered as rather an interested counsellor, but I think you may have observed in the newspapers lately letters from my friend on my right here (Mr. Weaver), which appear to me to demolish any chance that this new cable might have had of earning a livelihood. I may tell you that we have gone carefully into the figures and facts connected with the laying of another cable, and I may say that if it comes to a question of hostile competition, we can live and pay our working expenses at a rate of tariff at which it is not possible that that cable could pay its own working expenses. Of course, when I say we can live, it would be a very miserable existence, because we should merely pay our working expenses, and give you no dividend, which I need not tell you is a state of things which I should not like to cultivate, but, on the other hand, our competitors would not be able to live at all—not be able to drag out even such a miserable existence as we should be doing. If men, under these circumstances, are so unwise as to put their money into these undertakings, all I can say is they deserve the fate which I believe they will receive. We are told that these additional telegraphs are required in the interests of the public. The public want to have telegraphing cheaper than they have got it already. Now, it is not necessary to go back to the history of our company in order to show you the enormous reductions made by the board before the question of competition arose at all, in their own interests and with a view of stimulating and increasing the traffic, and thereby bringing in a larger income to the shareholders; but, gentlemen, there is another consideration which I have mentioned before in this room, and that is when such a competition as that which I have attempted to describe arises in which we can make a subsistence, and in which our competitor cannot live, depend upon it the next step in the interest of the public will be a combination for which the public will have to pay. There is nothing in existence more true than that you cannot compel capital to work gratuitously any more than you can force manual labour to work gratuitously, and attempt to force down remuneration of capital below what it will bear, the result to the public will be that they will have a large price for their accommodation, and they will have to remunerate the capital which it is attempted to crush in this fashion. That is my deliberate opinion. I believe that where combination is possible competition is out of the question. The public are interested in increased facilities and cheaper telegraphing, but they will have to pay a larger amount for the accommodation they will derive from these numerous cables than if they were satisfied with a fair rate of tariff from the cables which already exist, and which are more than sufficient to do the business which the public supplies them. Gentlemen, I do not think that it is necessary for me to trouble you with any more observations. This, as you are aware, is the off half-year. We have no dividend to declare, nothing of that description to bring before you, and we merely meet you for the purpose of keeping you fully informed as to the state of your undertaking and as to the condition of the company, and I shall, therefore, merely conclude by moving that the report of the directors and accompanying statement of accounts to June 30th, 1882, submitted to this meeting be, and the same hereby are, received and adopted.

Sir James Anderson seconded the motion.

Mr. Trotter said that he was quite certain that the board had exercised its best judgment in the administration of the affairs of the company, but he did think it was open to discussion whether their policy, as it had been explained to them, was the wisest possible. Their policy had been combination, to endeavour to create a monopoly. That policy was one which was not favourable to their interests, and he ventured to think that if there was truth in the remark of the noble chairman that the public would have eventually to pay for competition, it would come to this, that in any enterprise whatever the public would have to pay for all capital invested, whether well or ill. He did not believe in that. Upon the last occasion on which he had been present at a meeting of the company, about five years ago, he had just returned from America, after travelling some 25,000 miles in the country, and he then ventured to state his belief that the true policy of their company was not in combination, but in treating the public in a liberal manner, in being content in the first instance to make smaller profits, and meet competition as it arose. The tariff of one shilling for twenty words was anticipated as fatal to the prosperity of the telegraph companies; but they all knew how Mr. Rowland Hill was scouted when he prophesied success for the penny postage, instead of rates of 1s. 6d. and 2s. 6d. Now, he did believe that every combination, every endeavour to create a monopoly, had resulted in a considerable fall in the value of their property (hear, hear). He was seriously concerned to see their property at 50 per cent. discount, which meant a depreciation of its market value to one-half of the whole value. He thought the policy had not been successful, and he ventured to believe that if they had been content with the low rate per word, and had left the traffic to increase, as he believed it would have done, by itself, they would not have stood there that day to receive such a small dividend as they now did, or to see their property depreciated one-half in market value.

Mr. Aston said that the question was, was the meeting in favour of combination or not? If it was, then let it go on; but if the feeling was against it let them consider whether it would be wise to pass the resolution submitted before they strengthened the constitution of the board. He must confess that there appeared to him a great

lack of backbone on the board. With regard to the effect of combination there had been a great falling off in their value. In August, 1873, after the first combination, their stock was at 90; in May, 1877, it was at 60; in February, 1881, it was at 59; in July, 1882, at 52; and it was now something under 50. These figures were not satisfactory to him. It struck him, too, much might be said besides upon the question of combination. They had now a considerable reserve fund. He did not see why they needed to add to that; they could make a cable with what they had, and if not they should borrow. He did not like to see their stock standing at 50, and he thought they wanted a stronger board, with more strength and more backbone in it. He believed that there was now a vacancy upon it. He objected to that very much. If there was a number fixed they ought to keep to it. He would move that a committee be appointed, and that this meeting be adjourned for the purpose of receiving a report from them. He had nothing to say against the board individually, but he did think their policy ought to be opposed.

Mr. Henry Rutson said he only rose to support what had fallen from the last two gentlemen. This policy of combination had gone on for a long time, and it appeared to him not very successful. He thought they would strangle all these new cables if this meeting declared itself against all further combination.

Mr. Newton said that this company would soon have to take steps to fight these new companies. He had always advocated the policy of fighting. He objected to combination, because it was disastrous to the interests of the company. He would like to refer to one or two points in regard to the position of the company. The chairman had told them that they took up their cable from the middle of the Atlantic from a depth of 2½ miles and put in a new cable, and that they could pick it up as if it were in this room. That fact was one of the most tremendous facts that had ever been announced at their meetings (laughter). It established their property in such a manner that they need have little regard even for their reserve fund. They had been always accustomed to hear that the life of a cable was ten years. It was very clear that they had now got a substantial property, that they were really now remaining in it as investors, although they were very little else than speculators at the present moment, considering what a very fluctuating property theirs had been, and how serious was their position as regards competition and dividends. With reference to competition, it struck him that in America it was prosperity which brought new schemes into existence. He had read in one of the evening papers this week that there was a new combination established in America simply because there were such wonderful dividends coming out of them. In this country it seemed to him that adversity brought new schemes into existence. The adversity of shareholders in these companies was always the forerunner of a new competing scheme. There might be some connection between the two as regarded operations on the Stock Exchange. He had heard it explained as being a great mystery, and that the only explanation was that investors were crops of fools that were continually being gathered in by promoters. He thought the Atlantic afforded to cable makers a great field for plunder. Cable contracts amounted to a sum of money something like 1½ millions, and in that there was a vast deal of plunder. The makers of cables found some people, who were not fools, to provide the means of getting a contract. Out of every £100 subscribed there was a percentage for insurance. Then the cable was underwritten, and in all probability, notwithstanding that this European cable scheme had been knocked on the head as far as investors were concerned, it might come into existence from the fact that the cable was already underwritten, and the gentlemen interested protected by a system of insurance. The way to fight that sort of thing was that of combination, which they had always adopted. He was not going to say anything personal, or make remarks against particular directors, but he did wish to make a few remarks against boards in general. It was not the adversity of shareholders that brought those new companies into existence, it was the tremendous prosperity of the directors (hear, hear). If they allowed that sort of thing to go on, they would become speculators, and he could prove it. It was one of the abominations of the City of London that shareholders are plundered by directors of the highest character and reputation (laughter). He held in his hand a list of fees paid to directors in cable companies—companies which were controlled by gentlemen whose names appeared on various boards. He trusted he was saying nothing offensive—he was simply speaking in the interests of the vast majority of investors in this company—those who put their money into it for interest only. The duty of directors was something beyond that of merely receiving fees (hear, hear). In that list which he held, it was shown that the directors of telegraphs were receiving £34,525 a year, and yet when they were attacked all round, the directors did not fight for them (name, name !). He had not made it up with names; he was not going to mention names. It was a question simply of policy and principle—it had nothing to do with names. If he were to begin naming names, there would be simply animosities all round. He had seen animosities enough raised by the way in which he had attacked principles, and he did not wish to increase these by attacking names. He held a list of the fees in the Anglo-Brazilian, the Direct, the Eastern, the Eastern Extension, the Globe, the West Indian, the River Plate, and the Telegraph Construction. But the directors of the Telegraph Construction earned their money beyond all others—he would not cast a single reflection on the Telegraph Construction. If ever a board of directors earned their fees, it was that one. He simply included it because it belonged to that charmed circle which they so often saw referred to in the newspapers. Well, in that number the fees paid amounted to £21,750. On these prospectuses they would find magnificent institutions—institutions which there was no equal to. The London and Westminster Bank actually figured there in a prospectus which was the concoction of a gang of speculators. Great dock companies were also represented on the board, who came forward with a subterfuge calling themselves trustees. These gentlemen were not fought as they ought to be. They should have fought the last French cable to the death not only of the shareholders but of the directors as well (hear, hear). But what did they do when they came to the point of destruction of the property? They left the men who were responsible for it untouched; the trustees, who were always trustees before they became directors, in the comfortable possession of some thousands a year. Some of these gentlemen earned more as directors than they would ever have done had they been twenty years in the business they "directed." That was the point to which this company should direct itself, and to which a committee should direct itself, that the question should be fought not merely as against the proposed new schemes, but against those who were behind the schemes, and names never mentioned except at meetings of the shareholders. The French scheme was fought so far, but they did not fight the directors on that occasion. They allowed one whose name should never have been allowed to remain on any board to remain at that board (oh, and name). It was not for him to mention names. Those who knew these things as he did should look for themselves. That statement of his could not be disputed, and they must sooner or later fight them to the complete death, and not to the half death, in the interests of their shareholders. Punish the shareholders, but punish the directors too, and let the latter have the most of it. Don't let directors sink into splendid positions—sinecures—where they barricaded themselves with proxies, and got an annuity for the rest of their days whether they worked or not. With reference to the European, American, Canadian and Asiatic Cable Company he found that it was now on its very last legs. He might tell them that, for he had seen a circular sent out in the usual way, which was an announcement that if any of their stock was disposed of there would be a large commission given for doing so. That only bore out what he had said of the margin which lay between the capital of the real money received spent in these commissions, and in sums for insuring.

Mr. Griffiths thought that the application of the word *combination* to the company was not a fortunate one. The company had started with a moderate capital, and the stock had been watered. Mr. Newton had made some very able remarks, and certainly it was not wise that they should continually combine with other companies if the combination was merely for their advantage; but he hardly agreed with all that he had said as to the question of policy. He thought they might gain much more by the development of telegraphy and by allowing affairs to take their own course. Nine-tenths of the commerce of the world was carried on through the agency of the telegraph, and as commerce increased so must telegraphy; but whether they combined for peace or war he could not say that he thought the policy pursued during the past twelve months had been altogether satisfactory. They had lowered their rate to one shilling, and for nearly ten months they had carried messages at a price which was hardly remunerative. What wonder was it if the dividends fell off? They were fortunate in having on their board gentlemen of great ability; but on the other hand, they should remember the remarks of Mr. Newton, that there were gentlemen of great ability who were not on the board (laughter). He should certainly be in favour of combination or of getting a few of such directors on their board. An increase in the number of their counsellors would take away from the enemy the chance of so well managing their schemes. He thought by that means that they would be more likely to retain their dividends than by lowering their rate and anticipating warfare. The present position of their company was somewhat critical. He was sorry to hear Viscount Monck remark that they could not compel capital to work gratuitously, at least, if so, that the public would ultimately have to pay for it. That was somewhat ambiguous. It was true the public might have to pay by subscribing additional capital; but he was afraid they would also have to pay for it by losing their dividend. He thought, therefore, it would be wise to follow the plan already suggested, that they should rather look to the increased development of trade, and seek to gain their fair proportion of the trade than go to war and lower their dividend to so great an extent. They would also by that means avoid the necessity of having such large renewal funds.

The Chairman: I am very unwilling at a meeting of this kind to appear to intervene before full discussion has taken place, and I have therefore abstained from stating my views at an earlier period of the resolution which has just been placed in my hand by the gentleman at the other end of the room. Now, gentlemen, you are all aware that this meeting is not one which has been called for the purpose of discussing the action of the directors or the constitution of the board, or anything of that sort. No notice has been given of this amendment, which has been sprung as a surprise upon us in the room without our knowing that there was any intention of anything of the kind. It is not an amendment of the resolution which I had the honour to propose at the opening of the meeting, because that resolution merely referred to the report and accounts which have been laid before you, and according to the established rules of order which guide all meetings, it is therefore entirely out of order, and I should be acting exceedingly improperly if I allowed it to be put to the meeting. But, gentlemen, there is another reason which I wish to lay before the meeting quite independent of the question of order. It is this: There are in this company upwards of 5,000 shareholders. No action of the board attacking the interests of the company has ever been taken—I mean any considerable action—without these shareholders having been called together, consulted, and allowed the opportunity of expressing their opinion upon it (hear, hear). On no occasion of this description has there ever been any opposition to the action of the board. I might almost say that literally; but, at least, if there has been any partial opposition it has been of such a character as ought to bring out into stronger light the unanimous support which the board receives from the great bulk of the shareholders. I have no personal feeling in the matter, and Mr. Newton may be perfectly certain that I entertain no opposition to his discussing my position in any way that he likes, but I do not think it is fair to the board, or fair to th

shareholders of the company, to allow a meeting such as I see before me, however respectable the individual gentlemen may be, a meeting which numerically bears no proportion whatever to the shareholders of the company, I do not think it would be right for me in such a meeting, even if the amendment were quite in order, to allow it to be put. If any dissatisfaction of the action of the board is felt, let notice be given fairly at a half-yearly meeting. If it is considered to be of such an urgent character as to require to be discussed before the next half-yearly meeting, the articles of association provide means by which, within a very few days, we can get the shareholders together, and get their opinion honestly and fairly upon any proposition which might be made to them; but, gentlemen, I cannot stand here, if even this amendment were in order, and allow it to be put to a meeting numerically composed as this is, in the absence of the majority of the shareholders. It is no disparagement to the gentlemen present to say that they are a mere drop in the ocean compared to the number of shareholders in the aggregate. On both these grounds I, as chairman, decline to put the amendment to the meeting. The articles of association provide that an extraordinary meeting may be called if the requisition, by any number of shareholders not fewer than five, and holding in the aggregate not less than 5,000 shares, with a full statement of the object of the meeting, be delivered to the secretary or left at the office. That is the course provided by your articles of association for considering such a proposition as this. I challenge those who have brought forward this proposition to take the constitutional course provided by these articles, and I shall be ready to meet them foot to foot and hand to hand whenever they take that course and propound their resolution before a meeting of shareholders properly called for the purpose of considering that resolution.

Mr. Aston submitted that the resolution was entirely in order. He felt very much flattered by the objections taken by the chairman, because they seemed to imply that if the amendment were put the meeting would endorse and pass it (no, no). One part of the amendment was certainly in order, for the meeting had surely the power to adjourn. He would suggest an adjournment to the 3rd November, whether they appointed a committee or not. He did not see the use of calling shareholders together on every point that arose, and spending £18 or £20 in doing so. It was no new point that had been sprung on the board. All the world was full of the combination question. Had they not found themselves face to face with combination after combination and company after company? He did not wish to press this against the feeling of the meeting, but he was certainly in order in moving an adjournment. He did not come with a formal resolution prepared, but simply to express his feelings, formed with some deliberation, that there was not enough backbone in their board, and that they wanted new blood.

Mr. Newton thought it a misfortune and a mistake that the amendment was not allowed to be put. Those who came there did so at considerable trouble; those who stopped away did so for their pleasure, and he objected to a meeting of shareholders being prevented from an expression of opinion. The board unquestionably had the confidence of that meeting. He objected to resolutions being brought forward without intimation; but he did not object to a gentleman who felt aggrieved bringing the policy of the board before the meeting. If it was put it would only show who supported him, and so assist the board in forming an opinion in regard to the popularity or otherwise of their course of action.

Mr. Humphreys said that one objection taken by the chairman was founded on a perfect fallacy. All the shareholders had the same privilege of coming to a meeting of this kind as they who had come, and, therefore, if anything were done in the absence of those, they ought to suffer and not they who were present. To say that they should not entertain the question because the meeting was numerically small was a fallacy he must protest against as contrary to English law. In a parish vestry, for instance, the old parish could be taxed if only three parishioners were present; and in all meetings of this kind, those who were present could act as they pleased without considering those who were absent. In regard to combination, it was true that no sooner had they come to peace with a competing company than some other company rose up and they were again in hot water. But the question was, how could they stop it? He thought fighting was the best way to stop these new companies rising continually and claiming a share in their profits; and no doubt companies were formed simply in expectation of their coming to terms with them, and for nothing else. He did not think, however, that the laying of these new cables was injurious to this company, it was rather beneficial (laughter). Decidedly he did. If they could buy new cable at half the money they were made for where was the disadvantage? As to this new cable company it was not likely that anybody would give £100 for shares, while their own shares were at £50. The English people were not such silly folk as to give £100 when they could buy the same identical thing for £50. Therefore that new company was not altogether opposed to them, because cables naturally wore out, and it was something to get a new cable at half its cost.

The Chairman said that he thought his position had been rather misapprehended. The last speaker had told them that a meeting of shareholders had a right to do what they liked; but if they meant to conduct business in a business-like way, they must conform to the rules which regulated all meetings whatever, and to the constitution of the company to which they belonged. He, as their chairman, deliberately announced his decision that that amendment was out of order. If they were dissatisfied with that, he presumed that the theory of English law would apply, that there was no grievance without a remedy; but standing there as their chairman, it was his right to say what was out of order, and he deliberately pronounced that amendment to be so. The reference to the numerical character of the meeting was merely to show that he had not been actuated solely by a technical question of order, but that there was a substantial reason why they should not allow a small number of gentlemen to pronounce on the interests of the 5,000 shareholders of that company. He would now put the resolution to the meeting.

The vote having been taken, the Chairman said: I pronounce the resolution carried, with four dissentients.

Mr. Aston: The amendment clearly might be put.

The Chairman: The resolution is carried; I decline to put the amendment.

Mr. Burt, solicitor to the company, said that he had had considerable experience of such meetings, and he thought Mr. Aston must be well aware that it was irregular to put such an amendment to the meeting, and he begged to say that the chairman was perfectly warranted in the decision come to, not only by the ordinary rules of conducting public meetings, but by the particular regulations of the company. He should be exceedingly sorry if such a thing had been done without any notice whatever, which would have been a great injustice to all the shareholders.

Mr. Aston said they were perfectly within their right in adjourning the meeting. (Mr. Aston then left the room, making use of a strong expression against Mr. Burt.)

On the motion of Mr. Newton, seconded by Mr. Smith, a vote of thanks to the chairman was then unanimously adopted. The chairman briefly responded, and the proceedings terminated.

SOUTH EASTERN (BRUSH) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary meeting, followed by a statutory meeting, of the above company was held on Wednesday last in the City Terminus Hotel, Cannon Street, General Sir Michael Kennedy, R.E., chairman of the company, presiding. The Secretary having read the notice convening the meeting,

The Chairman said: Gentlemen, this is a special meeting convened for the purpose of making certain alterations in our articles of association. These alterations have been dictated to us by the Council of the Stock Exchange, and it is necessary that they should be made before the Stock Exchange will grant us a quotation. They have already granted us a settlement, but we are not in a condition to apply for a quotation, inasmuch as we have not sufficient capital paid up, that is, under a recent rule of the Stock Exchange a quotation is not granted except in cases where capital is paid up to the amount of £50,000. The alterations we have met to consider are not very numerous or very important in their scope, and in no way affect the interests of the shareholders, and no doubt you will approve of them without any difficulty. The first is in article 4, and the object of it is to prevent the directors, without the assent of a general meeting, issuing any shares at a discount; that is, to prevent the directors from watering the capital. The next alterations are in articles 81 and 89, and they have for their object the reduction of the term of office of the first directors from the year 1886 to 1884. The next is the omission altogether of article 85; and this the Stock Exchange require to be expunged apparently for the reason that it would enable important considerations to be decided by correspondence, instead of being thrashed out in a general meeting. The alteration in article 100 is similar in its scope, but it has application to the directors; that is, to prevent in the same way the matters which properly ought to come before a meeting of the directors being settled by correspondence. That is all, gentlemen. With these remarks I beg to move "That the articles of association be, and the same hereby are, altered as followed:—

"(I.) By the insertion of the following words at the end of article 4, 'Provided always that no share shall be issued at a discount without the sanction of a general meeting.'

"(II.) By the alterations in articles 81 and 89 of '1886,' therein mentioned, to '1884.'

"(III.) By the omission of articles 85 and 100."

Mr. F. Fesser seconded the motion, which was then put to the meeting and carried unanimously.

The Secretary then read the notice convening the statutory meeting, and

The Chairman said: Gentlemen, this is our first statutory meeting. As usual on such occasions we have not very much to communicate to you. Electric undertakings, like all other enterprises of a similar character, require after their commencement to work on gradually to development. Up to the present time our work has been chiefly with preparation and organisation for the business which is no doubt before us as time goes on, and with the decline of the year, when the demand for electricity will no doubt become greater than we can expect it to be during the long days and short nights of the summer. The company was incorporated on May 2nd with a capital of £100,000 in 20,000 shares. 104,730, or more than five times the number offered, were applied for, and, including 400 paid-up vendors' shares, all these were allotted. As soon as we were in a position to do so we applied for a settlement, and the date of our application was June 3rd. A settlement was obtained on the 29th of that month, but under a recent rule we could not obtain an official quotation till capital has been paid up to the extent of £50,000. We did not consider it advisable to make a call of £1 per share due on June 1st, because we had no immediate prospect of utilising the money advantageously and we thought it would be more in the interests of the shareholders that we should not call up additional capital until we were in a position to employ it advantageously. We engaged offices at 110, Cannon Street, and we made arrangements by which we shared those offices with the Provincial Brush Company, and of which you are aware your directors are also the directors. Mr. Offor, our first secretary, we appointed our manager, as we thought his great experience in electric business in general, and of the Brush in particular, would be more advantageous than if we continued to employ him in the purely ministerial office of secretary. You are also fortunate

enough to have the services of Mr. Beeman, as electric engineer. This gentleman was Electrical Inspecting Engineer of the Anglo-American Brush Corporation, and had had charge of the City lighting. He is an officer of experience and of talent, and has patented several useful inventions in reference to electric lighting and appliances. Under our engagement with him we are entitled to share in all his future discoveries, and I may say we see the dawn of great advantages in that respect to us. I cannot, at present, enter into details. It would not be right or proper to do so; but I may say I see the dawn of the near approach of results which I think will be very advantageous to this company. Mr. Offor, Mr. Beeman, and our secretary, Mr. Jermyn, also act in similar capacities for the Provincial Brush Company, an arrangement which is beneficial and economical to both companies. As soon as our organisation had been completed we took plans to lay the foundation for the important business which is, I have no doubt, eventually before us. We advertised in the local papers in our three counties, and we circulated widely a pamphlet drawn up by our manager, which gives full information regarding our system—the Brush system, and with details of prices and cost of installations and other useful information. Our manager, our travellers, and some of our directors also visited some of our chief towns, and I may say they were everywhere well and favourably received, and I am bound to add in every case the answer was that however well disposed to us, they could not take any steps until the bill now before Parliament had become law. In addition to other business, we have carried out successfully a very large installation at Parkeston Bay, near Harwich, for the Great Eastern Railway Company. This I believe to be only the forerunner of a very much more extensive business in that direction. Generally, I may say, we have had numerous applications from firms and individuals in reference to installations in the use of our system, but we have been met by two difficulties; one is that which I have already alluded to, the want of legal powers, for getting down our mains, and means of supplying electricity; and the other with reference to a secondary battery or accumulator; which we find to be most important, and, indeed, an essential component part of every large system of incandescent electric lighting. Both these difficulties, I may say, are now in process of being removed, and will, I believe, shortly disappear. We have taken part in a very important movement, and have joined with the other Brush companies in forming a Brush council or conference, which will take into its consideration subjects of common interest, and will concert common action and protect common interests. Delegates from each of the companies concerned have already met, and have considered and arranged their future mode of procedure, and have already passed some important resolutions in reference to the quality and price of the machinery and plant which under our licences we obtained from the Anglo-American Brush Corporation. I think you will see that as all the Brush companies work under the same licence, but on totally distinct and separate ground and localities, that their united action must be very powerful and cannot but be very beneficial to the common Brush interest. I will now say a few words as regards the Electric Light Bill. All those concerned in electric lighting must have followed the course of this bill with a great deal of interest, probably not unmixed with a little apprehension. I was prepared to address you on this subject in a somewhat different strain, but I am happy to say that the bill in committee was yesterday amended in a very important particular, and the period for which licences may now be granted with the assent of the local authorities, was altered from five, as originally drafted, to seven years, and the period for which provisional orders can be procured, with the assent of the local bodies, has been altered from fifteen years to twenty-one years. This concession, taken in connection with the compulsory sale clause, is very important; but I think, gentlemen, that as far as lies in us, we should not stop here, but should endeavour by agitation and such means as may be within our power, to obtain a revision also of the compulsory purchase clause. That clause seems to me to be extremely inequitable, for it provides that electric undertakings should be compelled to sell their works at the close of the period named for the mere value of the plant and the material, without any allowance whatever for the goodwill of the concern. I do not think, gentlemen, that this clause can stand, but at present we must do the best we can as it has been amended. It is very encouraging to find that there is a general and growing opinion that there is a great and immediate future for electric lighting, and wherever this subject is discussed, whether it be in Parliament or out of Parliament, or in the columns of the public press, that view appears to be strongly held, and I for one am entirely in accord with the remarks made in a leading article in the *Times*, on the 7th July last, to the following effect: "that there was a vast field for electric work, and so far from having to educate the public to the use of electricity, as some would seem to think it required, those concerned in its distribution will be speedily applied to by more customers than they can deal with." Our own experience, I may say, already tends that way. As regards our action in connection with the Electric Light Bill, I may state that for some time past we have had under careful consideration how we should act. I cannot enter into details now. It would not be advisable to do so, but I can assure you our arrangements are such that we can take necessary action as soon as the bill is passed.

Mr. Robinson asked whether any operations were at present being carried on by the company, or whether any contracts were made.

Mr. Stewart asked whether they had carried through any negotiations for the sale of sub-concessions in their district.

The Chairman said that, besides the work at Harwich, they had negotiations a-foot in a great many places which would, he believed, be successful when the difficulties were removed which at present were interfered with by the state of the law, as to the opening up of streets, and getting in their mains and wires. As to the sale of concessions, the same difficulty was before them, and as soon as they had legal powers he had no doubt they should obtain applications for concessions in various quarters, but that was not likely as long as the matter remained uncertain.

A Shareholder asked whether it was intended to make a call.

The Chairman said that he had already explained that they did not call up any money because they did not require it at the moment, and they thought it was preferable to leave it in the shareholders' hands than keep it unemployed at their bank.

Mr. Stewart asked in what securities they had placed the money in hand, so as to be yielding the company a fair return.

The Chairman replied that the greater part of it was in their bank on deposit, yielding a small amount of interest.

A Shareholder asked whether the prospects of the company were as good now as they were at first. He thought that gentlemen there were very well aware that a great stimulus had been given to the gas companies by the bringing out of electricity, and it would be interesting to know whether gas was going to carry the day, or whether the electric light was likely to get into favour. There had been a very interesting statement made in Parliament lately, namely that upwards of 90 applications had been made for the introduction of electricity, and he thought they would like to know if this company was one of those that had made that application to the Board of Trade.

The Chairman said their prospects were certainly as bright now as they were when they first commenced; he thought considerably brighter, because they were now approaching a time when they could really take, as he hoped, effective action. Up to the present they had not been able to take any action for want of legislative powers, and, until they had these powers, they could not commence to compete with the gas companies, as he hoped they should be able to compete successfully.

In reply to another question, in regard to the obtaining of some accumulator,

The Chairman said that they had hopes and prospects of settling that very question soon. He could not say more at present, but he hoped they would be content for the time being with what he had said. He would add that this company was not one of the number which the Lord Chancellor had stated would make application. He had no knowledge whatever of who had made them.

Mr. F. Fesser (vice-chairman) said he should like to say a few words in reply to some inquiries made by gentlemen opposite him as to whether their prospects were now as bright as they were. When they issued their prospectus there was a mania raging, and a very great deal more was expected of the electric light and of the capital invested in it than ought to have been. At the present moment it seemed that they had rushed into the opposite extreme and fallen into a condition of despondence, and many of those who had thought the electric was the light of the future had begun to think that there was no hope of competing successfully with gas. Some remarks made had echoed that same feeling which seemed to be undermining the public sentiment. In his own opinion their prospects were very considerably brighter now, because the science of electric lighting, although new, was making such gigantic strides, and they were hearing every day of such enormous advances that they had not the slightest doubt it would supersede every other method of lighting. A great deal had been said of the result of the tenders for public lighting in the City, and he was sorry to say that most remarks that he had seen in the public papers seemed to show that the result of these tenders was incontestably that the electric light had proved five or six times as dear as gas, and it was quite impossible to compete, and that there was an end of the whole matter. Now, if they took any gas company in England, except that which happened to have mains laid down in those particular streets for which the City Commissioners had invited them to supply one year's lighting, and were to ask that company to tender for lighting it for one year, they would find that the gas would not be four or five, but twenty, and perhaps even fifty times more than the privileged gas company was at present charging. The terms of the electric light contract were that they were to supply the lighting for one year, that was, erect their plant and machinery, and remove it at the end of the year; on these terms it was impossible to compete with gas; but wherever electric lighting was allowed fair play, it was not only infinitely a more brilliant and wholesome and pure light, but very much cheaper. If any railway company were to erect any gaswork to do what they were doing at Parkeston Bay with the electric light, it would be quite too terrible, and they must act under the same conditions as those which the gas company acted—on the same footing; then they should then be able to compete with gas, but not before. He hoped that before many days they would have the law in their favour, and be able to lay down their wires on a fair footing. Then they must remember that the gas companies did an immensity of private lighting, and that enabled them to supply the public lamps more cheaply. The electric companies must have the same privileges. As soon as that bill became law he felt sure that they would be able to beat gas.

Mr. Hesse asked if they had a quotation.

The Chairman replied that they had not, as they had not yet £50,000 paid up capital.

Another Shareholder asked whether any formidable competition was likely to arise in their districts with other companies.

The Chairman remarked that they did not anticipate competition, but their Manager, Mr. Offor, would perhaps give them his experience on that point.

Mr. Offor said that the obvious answer to that question was that the survival of the fittest would be the rule that governed their success. They believed that the Brush system was the only practicable one at the present time, and therefore they felt confident that no competition could ultimately oppose them to any serious extent. The public mind was to a certain extent confused by the recent Crystal Palace Exhibition. A large number of lights were burning there connected with different systems, but without the slightest evidence of the cost of producing these lights. He might mention that the Brush system had been carried on in the City at a very small cost indeed compared with the lighting of similarly extended districts by Messrs. Siemens Brothers, whose light had now disappeared from

the City, owing to its great cost. The Brush light, in a circuit of 3½ miles, had been wrought from one dynamo machine running in their works at Lambeth; whereas the Siemens light required for a somewhat smaller circuit, he believed, 12 or 14 dynamo machines. He might mention also, that in the case of the installation at the Great Eastern Railway Company's station at Parkeston Bay, their contract was based upon their supplying the light within one week from the date of it. They had undertaken that, and done it within the week. That showed that the skill now at the disposal of the company was sufficiently efficient to enable them to carry out any work of that kind. He had visited many of the towns in their district, and had had a great deal of correspondence with officials connected with councils and local boards, and he found in all these towns that there was a gas interest opposing the electric light interest. In one town the people had determined that next November representatives should be returned who would support the introduction of the electric light, as opportunity offered. In addition to the installations there had been also many smaller installations for the purpose of making their light known without expense to the company, and they had done that by means of a portable apparatus which they could readily send from one part of the country to another, and with the aid of this apparatus in a few hours they could give the light of 12,000 candle-power. During the present week they had carried out installations of that kind at Richmond. On Monday they lighted an enormous fête attended by fifteen or twenty thousand persons. There in a few hours they had their lights installed and running, and it created a great deal of public interest, and would be followed, no doubt, by some arrangement being very speedily carried out by the local authorities of Richmond, who had now had an opportunity of seeing the light. Last night they lighted up a Blue Ribbon Army meeting, and considerable interest was manifested in the light. All this they had been doing in different parts of their district, and with the believed, very satisfactory results.

Mr. Robinson inquired whether the company had the power to light private houses?

Mr. Offor replied in the affirmative. The company possessed not only the arc lamp, which was suitable for the larger spaces, but also the incandescent light, which was suitable for smaller sized rooms. This company had a contract from one gentleman at Eltham, who was going to pay the company three times the price he had hitherto paid for gas, for the privilege of having the incandescent light in his house.

Mr. R. Cunningham (a director) said he might add that he had been to nearly the whole of the towns in their district. He had seen no competition, and their company had been first in the field.

No further questions being asked,

The Chairman said they had given the shareholders all the information in their power, which he hoped had been satisfactory to them as far as it had gone.

On the motion of Mr. Briers, seconded by Mr. Comberbatch, a vote of thanks to the chairman was unanimously adopted, and the proceedings terminated.

PROVINCIAL (BRUSH) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

On Wednesday, at the City Terminus Hotel, Cannon Street, under the presidency of Sir Michael Kennedy, an extraordinary general meeting of the members of this company was held for the purpose of considering and, if thought advisable, of passing as a special resolution certain alterations in the Articles of Association, which were to precisely the same effect as those set forth in our report of the South Eastern (Brush) Company, reported in another column.

The notice convening the meeting having been duly read by the Secretary, Mr. Alfred Jermyn, a resolution for alteration was moved by the Chairman, seconded by Mr. F. Fesser, and carried unanimously.

The first statutory general meeting was then held, in opening which the chairman repeated in substance the remarks he addressed to the sister company, the South Eastern Brush Company, and reviewed the prospect of more work for this company during the winter. The company, he added, was incorporated on May 8th with a capital of £200,000 in 40,000 shares. 134,376, or more than six times the number offered, were applied for, and the whole available number—20,000 shares—were in the first instance allotted. Owing to certain withdrawals, which the board considered had legal force, the total number now allotted was 19,841. As soon as they were in a position they applied for a settlement, and their application was dated the 13th of June. As, however, it took some time to settle such matters, they had not yet obtained a settlement, but they expected to do so daily. They shared offices with the South Eastern Brush Company, and the same officials acted for both companies. In addition to other business, the company had installed lighting at Bedford, High Wycombe, Sudbury, and Stowmarket, and they had had numerous other applications. Having alluded to the Electric Lighting Bill, to the Brush council or conference, and spoken of the position of the company in reference to them, he remarked that the company had matured their plans, and were prepared to put them into force as soon as the Electric Lighting Bill became law.

In the meantime, he might say, as regarded competition, that they had a good and well-tried system, and also an efficient and energetic manager (Mr. Offor). Frankly, he might say that as regarded ultimate results, he did not think there was much to choose between any of the principal electric systems; but it was not in that direction that they looked for their benefit. It was in the details by which those ultimate results were attained; and these were matters which would stand them in good stead. They believed their Brush system [illegible]n all respects, as regards the mode of producing the light, and of it, the fittest; and they had confidence that in the struggle for existence which was about to take place it would survive. If any gentleman had any question to ask he should be glad to give him an answer.

After a considerable pause, and no question being put, the chairman declared the meeting at an end.

A vote of thanks to the chairman and directors concluded the proceedings.

THE Stock Exchange Committee appointed Friday, the 11th inst., a special settling day in the following securities:—British Insulite Company, Limited, shares; Swan United Electric Light Company, Limited, shares; Australasian Electric Light, Power, and Storage Company, Limited, shares; all the above to be marked; Metropolitan (Brush) Electric Light and Power Company, Limited, shares; Railway Electric and Appliances Company, Limited, shares. The committee have granted a quotation in the following security:—Electric Light and Power Generator Company, Limited, 22,500 vendors' shares.

APPLICATION has been made for a special settling day in the Gulcher Electric Light and Power Company, Limited, shares.

TRAFFIC RECEIPTS.

The Cuba Submarine Telegraph Company, Limited. The number of messages passing over the lines of this company during the month of July was 2,948, estimated to produce £2,800, against 2,494 messages, producing £2,397, in the corresponding month of last year. The traffic receipts for the months of May, estimated at £3,300, realised £3,544.

The Direct Spanish Telegraph Company, Limited. The estimated traffic receipts for the month of July, 1882, are £1,846, as against £1,448 in the corresponding period of last year.

The Eastern Extension Telegraph Company. The receipts for the month of July were £30,070, against £31,751 in the corresponding month of last year.

The Great Northern Telegraph Company. The traffic receipts in July, 1882, were £21,640 from the 1st January to 31st July, 1882, £137,200, in the correspon[illegible] months of 1881, £137,166, and in the corresponding months of 1880, £131[illegible]

The West Coast of America Telegraph Company, Limited. The receipts [illegible] two weeks ended the 14th July were £1,825, against £1,675 in 1881. [illegible]

THE TELEGRAPHIC JOURNAL AND

Electrical Review.

Vol. XI.—No. 247.

THE RESISTANCE OF CARBON AND THE TELEPHONE.

It is a little curious that all through the telephone controversy during the past four or five years, and also in the recent lawsuits of Edinburgh and London, no mention has been made, as far as we are aware, of the experiments made as long since as 1866 by Mr. S. Alfred Varley with carbon lightning guards. It is well known that this gentleman has claims jointly with Sir Charles Wheatstone and Dr. Siemens to the discovery of the reaction principle upon which the dynamo-electric machines of the present day are constructed. In 1870 Mr. Varley read an important paper before Section A of the British Association meeting at Liverpool on "Lightning and Telegraph Wires," and this was published in our contemporary *Engineering* on the 7th of October in that year.

Mr. Varley, when experimenting with electric currents of varying degrees of tension, had observed the very great resistance which a loose mass of dust composed even of conducting matter will oppose to electric currents of moderate tension.

With a tension of, say, fifty Daniell cells, no appreciable quantity will pass across the dust of blacklead or fine charcoal powder loosely arranged, even when the battery poles are approached very near to one another.

If the tension be increased to, say, two or three hundred cells, the particles arrange themselves by electrical attraction close to one another, making good electrical contact, and forming a channel or bridge through which the electric current freely passes.

When the tension was still further increased to six or seven hundred cells the author found the electricity would pass from one pole to the other through a considerable interval of the ordinary dust which we get in our rooms, and which is chiefly composed of minute particles of silica and alumina mixed with more or less carbonaceous and earthy matters. Incandescent matter offers a very free passage to electrical discharge, as is indicated by the following experiments. The author placed masses of powdered blacklead and powdered wood charcoal into two small crucibles; no current would pass through these masses of powder whilst they were cold, however close the poles were approached, without actually touching. The battery employed in this experiment was only twelve cells.

The crucibles were then heated to a red heat, and electricity freely passed through the heated powder, and on testing the resistance opposed by the heated particles, placing the poles 1 in. apart, and employing only six cells, the average resistance opposed by the blacklead was only four British Association units, and that opposed by the wood charcoal five units.

These observations go to show that an interval of dust separating two metallic conductors opposes practically a decreasing resistance to an increasing electrical tension. Reasoning upon these data the author was led to construct what he terms a "lightning bridge," which he constructs in the following way:—

Two thick metal conductors, terminating in points, are inserted usually in a piece of wood. These points approach one another within about 1-18th of an inch in a chamber cut in the middle of the wood.

This bridge is placed in the electric circuit in the most direct course which the lightning can take, and the space separating the two points is filled loosely with powder, which is placed in the chamber, and surrounds and covers the extremities of the pointed conductors.

The powder employed consists of carbon (a conductor), and a non-conducting substance in a minute state of division.

We have now to consider the behaviour of the lightning bridge in a circuit struck by lightning.

The lightning finds in its direct path, not a space of air, but a bridge of powder, consisting of particles of conducting matter in close proximity to one another; it connects these under the influence of the discharge, and throws the particles into a highly incandescent state. Incandescent matter offers a very free passage to electricity, and the secondary current developed by the demagnetisation finds an easier passage across the heated matter than through the coils of a telegraph instrument.

The reason a powder consisting entirely or chiefly of conducting matter cannot be safely employed, is that, although in the ordinary conditions of things it would be found to oppose a practically infinite resistance to the passage of electricity of the tension of ordinary working currents when a high tension discharge occurs, the particles under the influence of the discharge will generally be found to arrange themselves so closely as to make a conducting connection between the two points of the lightning bridge. This can be experimentally demonstrated by allowing the secondary currents developed by a Rhumkorff's coil to spark through a loose mass of blacklead.

Mr. Varley made the following experiments to test the resistance opposed to the passage of electricity by powdered conducting matter:—

Two crucibles were filled with blacklead powder (the best commercial blacklead used for domestic purposes). Two crucibles were filled with powdered charcoal, obtained from a charcoal dealer. The battery poles of a 12-cell sulphate battery were placed half an inch apart in the powders, a horizontal galvanometer being included in the circuit, and no deflection was obtained either with the blacklead or the charcoal powder; the galvanometer employed gave a deflection of 50 deg. with 12 cells through a resistance of 65,000 ohms. The crucibles were then heated to a full red heat, and the poles of the 12-cell battery placed in the heated powder, and the resistance opposed by the heated powder in each crucible measured. The wood charcoal gave a resistance never exceeding 7 ohms. The blacklead gave a resistance never exceeding 6 ohms. The crucibles were then removed from the fire and allowed to cool, and tested again some days afterwards; the powders were now found to conduct when cold. The wood charcoal powder gave a resistance continually varying and ranging between 2,000 and 500

ohms. The blacklead gave a more constant resistance, ranging between 400 and 100 ohms.

Mr. Varley concluded from this that the effect of highly heating charcoal and blacklead appears to be to make the particles more dense and to bring them closer together, so that they conduct.

It seems highly probable that had Mr. Varley been engaged as a scientific witness in the late trials, some very interesting information concerning the behaviour of carbon in different forms under various conditions might have been elicited, as it is hardly probable that his experiments did not lead him to think of it in connection with matters other than that of his lightning bridge.

A great deal has been said about Clerac's tube of carbon for obtaining variable resistance, and we believe that it was in use before Mr. Varley's invention; still, we think that in justice to the researches of the latter, we should not allow the matter to be unheralded because at the time it formed the subject of no particular praise or called for much remark in scientific journals.

THE TELEPHONE INDUSTRY.

Mr. Fawcett, speaking in the House of Commons last Saturday, said :—"It was desirable also that he should remove all doubt as to the relations of the Government to the telephone companies, as there had been a great deal of speculation on the chance that the Government would purchase them. It was as well that the truth should be known, for he believed that it was altogether improbable that the Government would do so. Their policy was to encourage free competition. If the thing could be done best by private companies he could only say he should be delighted to see the whole telephone business of the country conducted by private enterprise. If, on the other hand, it was proved that the business was better done by the Government, the Government would have beaten the companies in the open field of competition, and could occupy the ground without being subject to claims for compensation."

We are pleased at the attitude taken by the Postmaster-General in this most important matter, and if the private companies can only have fair play, we may shortly hope to see an immense development of such a necessary adjunct to our business relations as the telephone. There are, however, several obstacles to be overcome, the chief one being the monopoly at present possessed by the United Telephone Company—at least in their own ideas. Even here the stumbling-block appears to be not so much in the receiving instrument as in the transmitter. A great difference of opinion still exists as to the amount of ground covered by Mr. Edison's single claim, and yet another battle must be fought over this subject. As far as we understand this Edison patent for a transmitter or tension regulator, it is limited in its character; but we believe that the United Telephone Company think it covers any semi-conductor placed in between any two points of a circuit, no matter how connected, or how constructed, as long as the impulses of the voice are directly employed to change the positions of the atoms composing the semi-conductor, and thus to vary the resistance of the circuit. This unsatisfactory state of affairs will, however, it is to be hoped, shortly be placed on a proper footing; for until such is the case, it is almost hopeless to suppose that the telephonic industry can make any great advance, even on the strength of the licences recently granted by the Postal authorities.

The telephone is no longer a novelty, yet we think our readers will be somewhat surprised at the table we now place before them.

We extract from the New York *Review of the Telegraph* [illegible] *Telephone* of July 15th, the following statistics of the [illegible]ss made in seven countries of Europe. Number of [illegible] subscribers in actual operation in Europe :—

IN FRANCE.

As the above statistics stand it would appear that private companies, and not the government, should have the telephone business; but as yet so little has been done in Europe that the data we have at command is scarcely sufficient to allow of the deduction of any decided opinions.

We will now leave our readers to compare the respective telephonic industries of these countries, and we shall look forward to the time when we are able to state that England holds the leading position in this branch of electrical work, which she does at the present moment in regard to the telegraph.

---

* Price of each subscription is same in every town, viz.: 200 marks (50 dollars), up to 2 kilometres and 50 marks (10 dols.) for each additional kilometre from the Central Bureau. To have a second or additional instrument in the same house and on the second line, the price is an extra 50 marks (10 dols.).

An income of 403,853,474 dols. during the year ending with June, 1882, was more than the government has received during any previous year since 1867, and the cost of the government, including pensions, was but 187,630,093 dols., leaving a surplus of 144,966,937 dols. after the payment of 75,258,439 dols. interest on the national debt. Unfortunately, the pension payment will be very heavy this year; but the interest on the debt will be 13,896,329 dols. less than it was last year. The customs receipts, the greatest [illegible] last year in all the history of the nation, 219,986,223 dols., [illegible] would be sufficient to maintain the government and slowly reduce the [illegible] national debt, were the internal revenue and income from [illegible] miscellaneous sources wholly to cease.

THE EDISON ELECTRICAL ESTABLISHMENT AT IVRY.

[We are again indebted to the courtesy of M. le Comte du Moncel for advanced proofs of the above interesting article, which appears in our contemporary *La Lumière Electrique*. Unfortunately it arrived too late for insertion in our last week's issue.]

The finest electrical establishment at present in existence in France, both as regards the size of the building and the plant, is that which has just been started at Ivry, near Paris, by the Edison Light Company. It belonged formerly to M. Alexandre, and was used for the construction of organs and pianos, and it is built in a part of the old park of Ivry. Besides the principal part of this establishment, which forms a large courtyard built in on every side, there are several wings of four storeys placed parallel and perpendicularly all round, which give to the whole the appearance of an admirably planned manufacturing city on a small scale. It is in these wings that the various machines are placed which are required for the manufacture of the apparatus which enters into Edison's system of electric lighting.

In one wing we find the lathes and tools necessary for the construction of the dynamo-electric machines of the Edison system. Several models are constructed which can individually maintain series of 17, 60, 100, 125, 150, 250, 500, and 1,200 lamps. Each part of these machines is manufactured in a certain workshop, and the coiling of the wires which necessitated special arrangements is performed in separate rooms.

In several other wings are the workshops devoted to the manufacture of the lamps. In one we see little blades of bamboo which come from Japan in boxes, and then pass through several hands to be reduced gradually to the required thickness, which is that of a sheet of paper, and at last cut so as to present the appearance of a slender filament, perfectly formed and terminated at the two extremities by a sort of expansion, by means of which it is fixed to the wires of the circuit. These different operations necessitate several workmen, who pass to each other in succession the blades of bamboo as they are fashioned, and the work is performed with machines admirably constructed and convenient to manage. In another part of the establishment the carbonisation of the filaments is performed. They are first put into little flat moulds, hermetically closed, which bend them into the shape of a horseshoe; and these moulds are so arranged, that during the carbonisation, which necessarily reduces the length and thickness of the filament, the horseshoe shape is constantly maintained. These moulds are then placed in graphite cases, hermetically closed, and these cases are in their turn put into furnaces heated to a high temperature. An entire building is set apart for this process, and the furnaces are constructed on an excellent model and simplify the work considerably.

The glass bulbs of these kinds of lamps are made in another part of the establishment, and their manufacture is effected in two different workshops. In one are constructed the glass tubes through which the platinum wires are fuzed, to which the extremities of the carbon filaments are to be attached; in the other are manufactured the bulbs into which these tubes are to be introduced with their carbon, and which are to be exhausted of air. It is curious to see with what promptitude these various operations are effected; and one can now easily understand that 500 of these lamps can be made in a day.

But what especially excited my curiosity is the manner in which the vacuum is obtained; it is quite an installation of a physical laboratory. Imagine in a large hall a sort of long enclosure, closed by three partitions about 2 metres high, and on the walls of which are externally placed in series 500 mercury barometer tubes, of a construction somewhat analogous to that employed by Sprengel; imagine adjusted to each of these tubes a lamp with its bulb not yet closed, and in the middle of the space enclosed by the partitions two large tubes of cast-iron, about 20 centimetres in diameter, communicating with the 500 tubes and connected with an enormous vacuum pump of Sprengel, and you will be able to form an idea of the importance which has been given to this process. The process of exhausting these lamps is, as has been often said, extremely important and very delicate; for not only should the vacuum prevent the combustion of the carbon filament, but it should also increase its tenacity. This is why it is necessary to proceed by several successive operations effected after longer or shorter intervals of time, during which the filament is rendered incandescent under the influence of a more or less powerful current. Thus the gases contained in the pores of the carbon are set free, its density increases, and its tenacity becomes sufficiently great to be comparable to that of a metallic wire.

Under these conditions filaments of carbon of the thinness of a hair can resist powerful jerks communicated to the lamp, and are not appreciably changed by incandescence. It is by this means that the lamps now used in the Edison system are warranted by the company to last 800 hours. There are besides many which have lasted nearly double that time, and it is even asserted that the mean duration is 1,200 hours.

One of the most important conditions of the Edison system is the complete uniformity of resistance of the carbonised filaments; therefore an entire testing apparatus has been arranged for the measurement of this resistance by the Wheatstone bridge and the Thomson mirror galvanometer. A dark room is used for this purpose, and as the filaments are manufactured, they are sent to the operator and classified according to their resistance. The carbons of the 16 candle-power lamps have a resistance of about 140 and those of the 8-candle lamps a resistance of 70 ohms. However, some are now constructed which have a resistance of 280 ohms, and which are made to give a light of 10 candles.

These carbons have the advantage of allowing of a greater division of the light from the same dynamo-electric machine, and this can be easily understood if we reflect that the total resistance of the outer circuit, which should be about equal to that of the machine, would become much less than the latter, if the number of derivations became too great, and in order then to obtain the equality of the two resistances, the resistance of each derivation must be increased. The measurement of the resistance of the carbons is not all that is done in the hall of which we are now speaking; the photometric measurement of each lamp, under the influence of a given and constant current, is also taken. For this purpose the Bunsen photometer is used, and for a standard light, a Carcel lamp, arranged on a balance, is employed, so that the quantity of oil consumed per hour can be measured. All these measurements are noted, and the lamps are grouped into different divisions, according to their resistance and intended luminous intensity.

Other workshops are also set apart for the joining of the carbon filaments to the platinum conductors, and for mounting the lamps on their supports. We know that the platinum wires are terminated where they meet the carbon by two little plates, arranged like the jaws of a vice, and between these plates are introduced the appendages which terminate the filament. In order to insure good contact, they are electro-coppered, and the joint becomes permanent. For this purpose several baths are placed separately in a room, and in each bath a great number of these joints can be coppered simultaneously. The plaster mounting of the bulbs on to their support is also done quickly and very simply, so that all the elements which enter into the construction of the Edison lamps are manufactured in the establishment. Only the fittings, suspensions, brackets, and candelabra of bronze, are left to Parisian industry, but they are constructed according to the models sent from America.

Besides the workshops of which we have just spoken, there are others set apart for the manufacture of the conductors, of different diameters, intended to supply electricity to the lamps through streets and houses. This department has only just started, and has not as yet the importance that it will have in the future; but it has necessitated a vast amount of space, and several buildings adjacent to the establishment will be employed for this work. We must also mention among the various departments of this industry, the rooms for designs of machines and of installations, rooms for packing, saw-mills, forges, and experimenting rooms, in which are placed steam-engines of great power.

The whole installation has been effected in six months, under the able direction of Mr. Batchelor, Mr. Edison's collaborateur, who is the engineering electrician to the com-

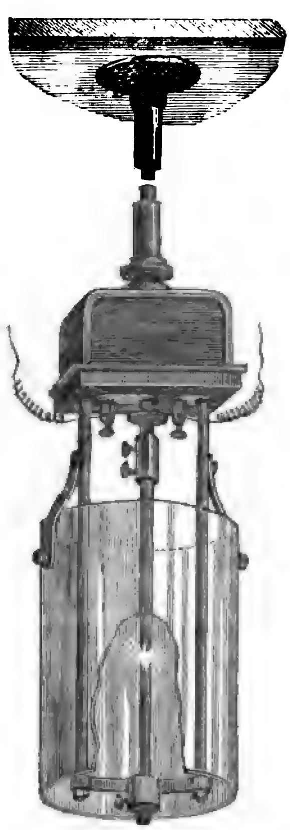
pany. It will not, however, be completed until the latter end of the year. We see that, unlike what has been done by many electric lighting companies, the one of which we speak is more interested in the practical side of the question than the financial, which is a safe guarantee of the reliability of the enterprise. Besides, it is known that already several installations have been established in various European towns, and we know that the company is receiving every day orders for France. As they are now in a position to carry them out, it is probable that we shall very shortly be able to judge for ourselves of the advantages of this system of lighting.

TH. DU MONCEL.

ELECTRIC LAMP.

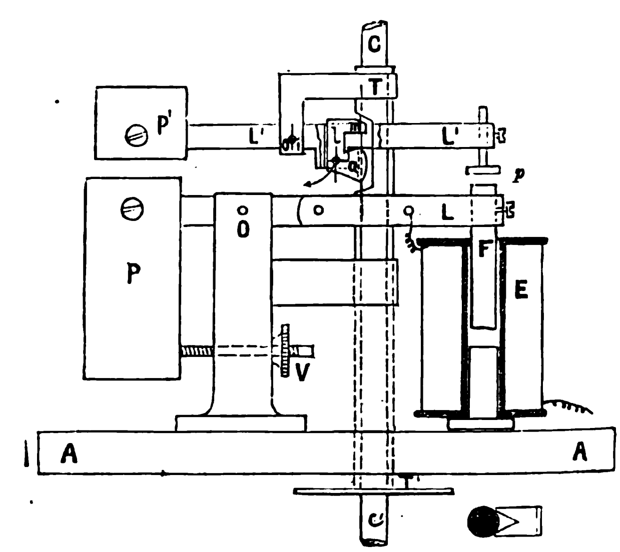
ROBERT MONDOS' SYSTEM.

This electric lamp has lighted the concert-hall of the Champs Elysées since the 1st May last, and an indefinite number of burners can be placed in one circuit, according to the electromotive force of the generating machine. The regulation is founded on the principle of derivation, the inventor having determined to dispense with all clockwork and all antagonistic springs, and has so arranged his apparatus that a single electro-magnet performs the two distinct functions of making and regulating the arc. The lower carbon is fixed on a strap suspended to the box containing the mechanism, the displacements of the movable upper carbon effect the lighting and maintain the fixity of



the arc. The mechanism represented in the diagram comprises an electro-magnet, E, the cores of which only occupy part of its length, about one-third; inside the coils, two rods of soft iron, F, suspended to a horizontal lever, L, turning at O and balanced by a weight, P, move freely. The screw, V, serves to limit the movement of the lever, L, to which is suspended a tube, T T′, traversed by a solid rod, C C′, which supports the movable carbon suspended to its lower extremity. The carbon holding rod, C C′, can slide freely into the tube, T T′, but it is prevented from doing so by a brake, *m*, *l*, *a*, the two extremities of which, *m* and *a*, in the form of a V, grip the rod, C C′, and hold it by friction in the tube, T T′. For this purpose, the tube, T T′, has an indentation opposite the brake. This brake is fixed on a lever, L′, L′, turning at the point, O′. The movements of the centre, O′, are distinct from those of the tube, T T′, on account of the square, T O′; the lever, L′, has an armature of soft iron, *p*, placed opposite the cores, F, and the action which the cores tend to exercise on this armature is counter-balanced by the weight, P′. When the apparatus is at rest the carbons are separated and the brake, *l*, *m*, *a*, maintains the rod, C C′, firmly held in the tube, T T′.

At the time when the current is sent into the apparatus, the carbons being separated, the current passes entirely into the coils, E, the rods, F, are powerfully attracted, the lever, L, swings and makes the entire system descend, whereas the armature, *p*, being powerfully attracted, loosens the brake and enables the rod, C C′, to descend freely until the two carbons come in contact. At this moment, the carbons being in contact, the current passes almost entirely through the main circuit, the power of the electro-magnet diminishes considerably; the levers, L and L′, then swing in an opposite direction under the action of the weights, P and P′, the entire system is raised and the arc is formed. As the arc lengthens in consequence of the consumption of the carbons, the current which passes through E increases in power, the cores, F, are more powerfully attracted, they attract the armature, *p*, with more force; the lever, L′, then tends to swing in the direction of the hands of a watch, the point of attachment of the brake, *l*, *m*, *a*, tends to recede from the rod, C C′, and consequently to loosen the brake which allows the rod to slide, and so shortens the arc. Practically the movement of L′ is inappreciable, and the rod, C C, slides by its own weight slowly and continuously. During this process of regulation the part, L, is immovable on account of the heaviness of the weight, P, and it only swings at the moment of lighting, when the arc is broken and the carbons separated. The regulator we have just described works with continuous or alternating currents as occasion may require. At the concert-hall at the Champs Elysées the burners are worked by an alternating current Siemens' machine; there are sixteen of them arranged in four distinct circuits.



The little vibrations produced in the mechanism by the alternating currents are very favourable to the working of this system, in which the carbon-holder is maintained by the friction of the rod between the tube and the brake. The apparatus can work with currents of very different intensities without changing any part of its mechanism.

In order that this object may be effected, the distance of the counterweights, P and P′, from the centres of the levers, L, L′, is adjustable; and, moreover, the relative position of the movable bar, F, and the armature, *p*, can be altered so as to obtain a very delicate adjustment.

At the concert-hall of the Champs Elysées [illegible] the lamps work normally with carbons 10 mm. in diam[illegible], a current of 10 ampères, and a difference of potenti[illegible] of 60 volts at the terminals of each lamp. The light pre[illegible]sents very great steadiness, and the mechanism is so simple [illegible] that the system has worked up to the present without any [illegible]itch.

TELEGRAPHS IN CHINA.

[We find the following article in the *Shanghai Courier*, and as we also receive private information that the facts are authentic, it may be of interest to many of our readers, and to all it will form a relief to the ever-recurring topic of electric lighting.]

Now that a land line of some 900 miles in length, connecting Tientsin with Shanghai, is erected and open for the transmission of public messages, it may be worth while to examine the future prospects of telegraphic enterprise in this country, and to view the probabilities of further extensions. This line, with a line from Tientsin to Taku and Peh Tang, is, we believe, the property of the Chinese Government, and is managed exclusively by Chinese officials, and worked by some six or seven operators of the Great Northern Telegraph Company. The erection of the line was entirely due to the scare induced by the anticipated war between Russia and China in 1880-81, and the money granted for the cost of construction was voted by the "Imperial Defence Bureau."

It is somewhat curious to speculate as to the reason why the long-shown antipathy of the Chinese Government to telegraphs was gradually swept away from the celestial mind. Up to the year 1876 the most violent dislike to anything telegraphic, necessitating posts and wires, or any visible obstruction to the beneficent influences of Fung Shui, was always manifested—witness the prolonged but abortive attempt of the Great Northern Company to erect a land line from Foochow to Amoy. But in 1877 a distinct change in their policy took place. As soon as the Chinese Government found it possible that native clerks could be taught to work the Morse telegraph instrument, and native workmen could erect land lines, permission was given to build a line, and a line was accordingly built from the Viceroy Li Hung Chang's Yamen to the Torpedo College, by Mr. Betts, the torpedo engineer to the Chinese Government. This was speedily followed by a line from Tientsin to the numerous forts at Taku and Peh Tang. The great convenience of this line was at once apparent to the Viceroy, for military orders could be transmitted and a reply received immediately. The first official message sent over the line was an order from the Viceroy to the Commander of the forts, to "dress" the forts and men-of-war, and fire a salute of twenty-one guns on the arrival of the U.S.S. *Ashuelot*, with General Grant on board; and to report the vessel on being sighted at Taku.

In 1880 it was decided to connect Shanghai with Tientsin for the purpose of enabling Li Hung Chang to receive news from the outer world and to confer with his colleague at Nankin, with a view of devising measures for the defence of the Yangtse from Russian attack. The Great Northern Telegraph Company obtained the contract to build the line, and at once commenced work. Without the slightest opposition from the people the line was built and opened for traffic in December, 1881; a marked contrast to the attempt at Foochow in 1874-5, where, after two years of futile efforts, the line was abandoned.

An extension from Chinkiang to Nankin has been determined upon, and further extensions are projected. If these extensions are carried out they will have a very important bearing upon the value of foreign cable property in the Far East. The next line which is proposed is from Nankin to Hankow, and if this line is built it will no doubt act as a very valuable feeder to the cables in the tea season; but should the contemplated extensions to the South of China be carried out, and the lines remain in the hands of the Chinese Government, it will inflict a very serious blow to the prosperity of the Great Northern cables.

The Great Northern Telegraph Company at present have cables from Hongkong to Shanghai (looped into Amoy), thence to Nagasaki, thence to Wladivostock, where the cables join the Siberian land lines. These cables were laid in 1870, are technically known as "Hooper's" core, and vary from 1½ tons to 18 tons per knot. The insulation of the cables is said to be in a very bad state, so bad that heavy battery power is employed on some sections, and break downs, as we all know, are of frequent occurrence. In January of the present year the cable was broken in three places at the same time, viz,, south of Gutzlaff, north of Gutzlaff, and between Shanghai and Gutzlaff. These faults had not been repaired more than a week or two when, on February 12th, the cable was again broken near Amoy. Before the cable ship could return to Shanghai after repairing the fault, the cable was again broken between Shanghai and Nagasaki. This two months' state of affairs may be considered but a fair sample of the condition of these cables, and in no way exceptional. Naturally much dissatisfaction is felt by the Shanghai public at these constant interruptions, and coupled with the angry feeling caused by the excessively high word-rate, would lead it gladly to use any alternative route if open to it. Should the Chinese extend their land lines to Canton and thence to Hongkong, such a route would be opened, and the European traffic would undoubtedly pass over the cables of the Eastern Extension Company; while of the local coast traffic, at least the greater portion would be diverted from the Great Northern cables (even when working to the Chinese land lines).

It is no doubt a consideration of these facts which is so strenuously urging the Great Northern Company to attempt to obtain from the Chinese a concession for the construction of land lines in China.

A land line from Shanghai to Canton, thence to Hongkong, in their own hands would practically duplicate 1,000 miles of cable, south of Shanghai; while a line from Tientsin to Pekin and thence to Kiachtka on the Siberian frontier, would duplicate about 1,000 miles of cable and some 1,200 miles of land lines, as far as European traffic is concerned. As these cables must sooner or later be renewed, at an expenditure of some £300,000 sterling, unless the control of the land lines can be obtained, the importance of the question to the Great Northern Telegraph Company cannot be overlooked, and it is certainly to be hoped that in the interests of the world at large, and Shanghai in particular, the land lines may be built, whether by the Chinese Government or the Great Northern Company is a matter of small importance to the public, so long as the residents in Shanghai have some reliable means of getting a message through to Europe.

THE MAGNETO-SOUNDER.

FIELD TELEGRAPH WITHOUT BATTERY.

In certain special cases, under favourable conditions, the telegraph lines can be extended to battle-fields. However, notwithstanding their lightness, they cannot be moved easily enough to follow up the manœuvres, and very frequently their fragility would render their preservation a matter of great difficulty in the midst of military operations.*

On the other hand, it must be admitted that it would be useless and impossible to use the telegraph at a distance less than six kilometres from the front of an army in action; useless, because, it would be quicker to send messengers; impossible, because it could not be worked under fire. However, for communication between the main guard and the sentinels, or between the batteries and the posts of observation, endeavours have been made to fit-up light telegraphs, capable of being conveyed by a few men; these may be called advanced post telegraphs. Each installation generally contains one kilometre of cable, which enables lines two kilometres in extent to be filled up between two stations.

At the time of the discovery of the telephone it was thought that this new instrument was destined to take the place of these telegraphs. But the experiments during the Russo-Turkish war soon showed that the noise of an army almost always, except in the silence of the night, prevents the voice from being heard. The most perfect telephones were however known at that time, those constructed by Siemens at Berlin and by Gower at Paris.

The microphone even does not amplify the sounds sufficiently to render them perceptible under all conditions. It requires a battery, which is cumbersome and necessitates a certain regulation of position in relation to the vertical,

* "La Télégraphie Electrique de Campagne." By Van den Bogaert, officer of the Belgian Engineers.

which is inconvenient. Finally, it must be placed on a fixed stand, for it produces deep sounds when vibrations are communicated to its support. It has therefore been rejected altogether; as to the telephone, it has been admitted that under certain conditions, it can be of service, and in the greater number of armies, it has been added to the light telegraphs already in use. The following are some of the different systems.

(A.)—Systems with Permanent Signals.

I.—*The Prussian Telegraph of Bückoltz*, employed by the Company of Belgian Campaigning Telegraph Operators. This apparatus has a return wire and is worked by a continuous current, *i.e.*, when there is no transmission, the current passes through the line and gears the clockwork mechanism: the signals are then produced by the interruption of the current, which throws the mechanism out of gear. Consequently, directly the cable is cut, the operators become aware of it.

The instruments work together, *i.e.*, the despatch is recorded simultaneously at the two stations. A recent improvement enables us to pass from the continuous current to the ordinary current by means of a commutator.

A complete installation comprises:

(1.) A case $0^{m.}\ 15 \times 0^{m.}\ 14 \times 0^{m.}\ 15$, containing the galvanometer and the manipulator. The last model is somewhat larger.

(2.) The battery, consisting of 12 Siemens elements with sulphate of copper. It weighs 12 kilogrammes.

(3.) Two coils of 500 metres of cable with two wires, one carried in a sort of infantry bag, the other in a case.

II.—*The Russian System of Dereviankine* is very similar to the above; the earth is employed as return conductor.*

Remarks.—The field telegraphs of Bückoltz and Dereviankine are the only ones that give permanent signals. They are excellently arranged; we think it would be impossible to condense any further the component parts, which are essential if we wish to keep copies of the despatches; but this does not seem to be altogether necessary. In America, on almost all the permanent lines, the despatches are sent by sound alone, and in campaign telegraphy it is very seldom that important orders are transmitted of which it is necessary to keep a copy.

(B.)—Systems with Momentary Signals.

(*a.*) *Optical Telegraphs.*

I.—*Trouvé System.*—This is only a miniature, about the size of a large watch, of an ordinary dial telegraph, with simplified mechanism. The receiver is worked by clockwork; the manipulator is worked by a button similar to that in keyless watches. The wet battery and a kilometre of cable are placed on a yoke to be carried on a man's back.†

II.—*Wheatstone One Needle System* (in use in the Spanish army).—It comprises as a receiver a vertical galvanometer, the needle of which deviates to the right or to the left, according to the direction of the current transmitted. The deviations to the left form the dots, and those to the right the dashes of the Morse alphabet. The manipulator, which resembles all those of the Morse type, is worked by reversals of the current; it is placed above the galvanometer, which is only 8 or 9 centimetres in height.‡

III.—*Prussian Needle Telegraph with Earth Battery.*—This system is similar to the preceding one; the current is supplied by two pieces of zinc and copper, which are buried in the damp earth. It was used during the war of 1870.§

Remarks.—The Trouvé system is very delicate; the two others are more solid and better suited to military operations. But it is very difficult to read the Morse signals indicated by a needle, and it cannot be used at night. As a sound can be heard at any time, sounders are preferred to the above instruments.

(B.)—Sounders.

I.—*The Caton Sounder* (employed exclusively in the military telegraph of the United States).—It is simply an electro-magnet, the armature of which forms the sounder. It is contained together with the manipulator in a little case, $0^{m.}\ 15 \times 0^{m.}\ 06 \times 0^{m.}\ 04$.

The battery employed contains several elements with sulphate of copper.

II.—*The Sounder of the French army*, smaller in size but similar to the preceding one, employs a wet battery or a reversible one.

III.—*Dereviankine's Russian Sounder*, also similar to the Caton sounder, is only $0^{m.}\ 10 \times 0^{m.}\ 08 \times 0^{m.}\ 05$.

IV.—*The Spanish Sounder*, with dimensions similar to those of the French sounder.

V.—*The Trouvé Sounder* has the appearance of a large watch. The accessories are the same as those of the portable telegraph by the same inventor.

Remarks.—All these sounders have the inconvenience of requiring a somewhat powerful, and consequently cumberous, battery. The Trouvé battery is the lightest, but the apparatus worked by it has rather a limited value. At the time when it was shown by experiment that the telephone was of little use to reproduce speech at the vanguard of an army, it was found that under the influence of battery currents, and especially of the high tension currents of induction coils, this apparatus gave sounds of great intensity. When a current is sent into the circuit of a telephone the magnetism of the magnet which constitutes it varies, and the result is a variation in the action of this magnet on its diaphragm of soft iron. Two different sounds are then heard, one when the current is established, the other when it ceases, and thus long emissions can be distinguished from short ones, as in the Morse sounder.

In order to produce a sound of greater intensity, serving to warn the correspondent that the transmission is about to commence, the interrupted current of a little Ruhmkorff coil is employed; a continuous current can also be sent into the line, the interruptions being produced by the plate of the telephone itself, by arranging it like the armature of a trembling bell. (Captain Ferrodon's alarm.)

The instruments constructed according to the above principles are:—

(C.)—Telephonic Sounders with Battery.

I.—*The Racagni-Guglielmini System.**—These inventors arrange their induction coil either in the handle of one of the telephones, which also contains the manipulator, or on the reversible battery, which has the form of a cartridge-box. They employ an electro-chemical receiver with paper band, which seems to have the drawbacks of the Morse system without possessing its advantages.

II.—*The Mangenot System* is identical in principle with the preceding one. The battery is also in the form of a cartridge-box, and contains the manipulator and the induction coil. The inventor, acknowledging the inconvenience of his battery, which is never hermetic, and which becomes polarised, proposes to substitute for it a Clarke machine, weighing $2^{kg.}\ 500$. In the event of it being impossible to hear sounds, he proposes to receive by the sense of touch, by placing the lips on the terminal of connection of the telephone. It will be remembered that a very skilful telegraph operator in 1870 received a message in this manner across a cable submerged under the Seine; but this was really a feat which would require no common degree of skill to perform.

Remarks.—All these instruments have the drawback of requiring cumbrous batteries, which the slightest accident would render useless, and which require great care. M. Mangenot proposes to substitute for them an induction machine, which is too heavy and which presents the great disadvantage of requiring a man to turn the handle. The solution of the problem must evidently be sought for among the following instruments:—

(D.)—Telephonic Sounders without Battery.

I.—*Colonel Jacobi's Télékal.*—The complete installation comprises a long-distance telephone, and a case $0^{m.}\ 21 \times 0^{m.}$

* Electrical Exhibition of 1881, Italian section, No. 1,605.

$11 \times 0^{m\cdot}33$, weighing from five to seven kilos., and called the *Télékal.** It is furnished with a Morse manipulator, worked in the ordinary manner; by means of a little handle the manipulator can be made to ring so as to call the correspondent.

We can also employ for this purpose the trumpet call with which long-distance telephones are supplied, whether constructed by Siemens or by Gower.

The advantages of the télékal are, according to the inventor, that it can be worked without battery to considerable distances, far beyond the limit at which the voice can be heard without being affected by the telegraphic transmissions of neighbouring wires or external noises. It requires no regulation of position like the microphone, and is of great solidity.

We have in vain sought for information on the principle of this apparatus; its inventor preserves absolute silence on this subject.

II.—*The Magneto-Sounder.*—It seems to us that the télékal was still very heavy and very bulky. We have therefore sought after an apparatus which should offer the same advantages, but have less weight and less bulk. Fig. 1

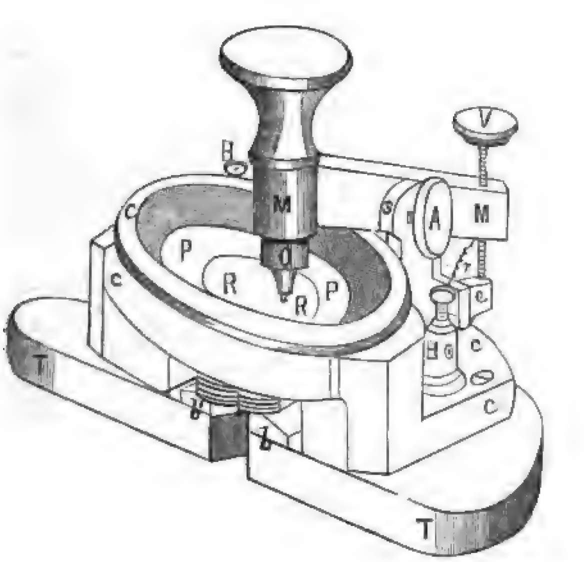

Fig. 1.

represents the arrangement at which we have arrived. A plate of soft iron, P P, is firmly fixed into a frame of copper, c c c, facing the poles of a flat horse-shoe magnet, T T, similar to those of the Gower telephones (*see* fig. 2). These

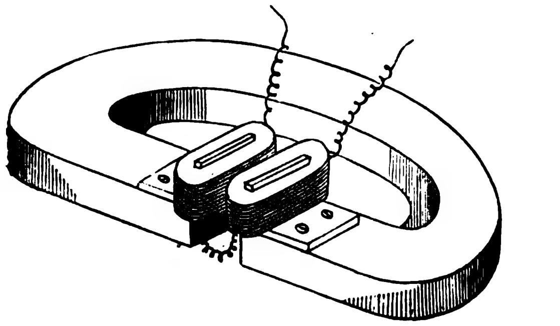

Fig. 2.

poles are, as we know, placed opposite one another, and very close together; on each of them is screwed a little square of soft iron, enveloped in a coil of very fine insulated wire. This wire is coiled in such a manner that the current passes in a contrary direction in the two coils.

The two free extremities of the wire are soldered on to the terminals, B B, the plate, P P, has a projection, *i.e.*, it bulges out in the centre so as to be elastic under pressure like metallic castanets. This pressure is produced by a small Morse lever, M M, supported by the projection, S, of the frame of copper, c c c, by means of the axle-screw, A; V is a regulating screw which serves to limit its play, and r, an opposing spring.

The apparatus thus constructed only weighs 250 grammes more than the magnet which forms part of it, or 750 grammes in all. It can be contained in a box, $12^{c\cdot}5 \times 9^{c\cdot} \times 5^{c\cdot}$, only the button of the manipulator, and the two terminal screws, B and B′, being left out.

In order to use it the terminal, B′, is connected to the line, and B to one of the poles of a Bell telephone, the other pole being connected to earth, as is shown in fig. 3.

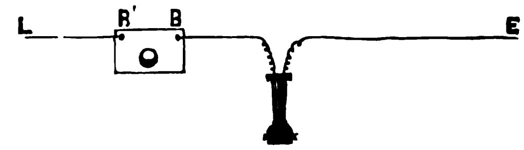

Fig. 3.

When used in active service, the magnetic sounder is suspended on the breast by a strap, and the hilt of a sword stuck into slightly damp soil forms an earth. The operator then works with his right hand as with the Morse manipulator, and applies the telephone to his ear with his left hand. In order to make the working of the apparatus clearly understood, we must first explain that of an ordinary telegraphic sounder.

In the written Morse alphabet, the different letters are represented by combinations of dots and dashes. The telegraphic receiver reproduces these dots and dashes on a slip of paper by the pressure, more or less prolonged, of the armature of an electro-magnet, which is lowered every time the current passes through, and is raised by means of a counteracting spring. In this system ·— represents *a*.

It does not work in this manner when the signal is received by the ear. The movement of the armature is limited by two stops, when it falls it strikes one of them and produces a sound, when it rises it strikes the other and produces another sound. We can therefore note the duration of the time it is lowered; if very short the two different sounds interfere with one another. Thus *a* is represented by (●×) ● × if we represent by ● and × respectively the sounds of the falling and rising of the armature.

In the *magneto-sounder* the transmitting mechanism is identical with what we have just described. When the plate is brought towards or drawn away from the coils a current is produced in them arising from the increase or decrease of the magnetic action on this plate acting as an armature. Currents are thus sent into the line and produce sounds in the receiving telephone.

The apparatus constructed by Richez & Cie., at Brussels, has fulfilled all our expectations. We have tried it on a telephonic line and were able to correspond freely. We introduced 6,000 Siemens units, *i.e.*, about 600 kilometres of telegraphic iron wire 4 millimetres in diameter into the circuit without producing any appreciable effect on the clearness of the sounds received; we had no further resistances at our disposal, but everything led us to believe that experiments made on long lines would be crowned with success. The new apparatus can, therefore, be substituted for the Morse sounder in all its applications. It has the advantage of being very light, of not requiring any battery, and of being extremely sensitive. Finally, it comprises a telephone which can be used in the ordinary manner.

The above description of the magneto-sounder for field telegraphs is an extract from the *Revue belge d'Art, de Sciences, et de Technologie Militaires, septième année* (1882), *tome* II., and is written by Lieutenant L. Weissenbruch.

* See the original description by the inventor in *La Lumière Electrique*, 3rd year, No. 35.

Danger from Electric Lighting.—We are informed that an inquest is to be held on the victims of the accident which we noticed in our "Notes" of last week as having recently occurred in the gardens of the Tuilleries in Paris. M. C. M. Gariel is charged with the technical part of the inquiry, and Dr. Bronardel with the autopsy of both bodies.

THE PRINCIPLE OF CARBON TELEPHONES.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—In reference to the principle of carbon telephones I have made the following experiment, which, I think, will interest your readers. On one side of a block of gas carbon, 155 mm. long and about 30 mm. diameter, I bored two holes, 7 mm. deep and 110 mm. from each other. They were then filled with mercury, and the arrangement placed in circuit with a battery and telephone by means of *amalgamated* copper wires dipping into them. On striking the block with a ruler the blows were loudly heard in the telephone. The block was then placed on a piano, every note of which was distinctly audible; and even speech was faintly heard.

Yours faithfully,

F. DE WOLFFERS, FILS.

56, Portland Place, Clapham, S.W.

August 11th.

THE TELEPHONE.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—It seems evident to me that Mr. S. Thompson, in his reply inserted in the last number of your journal, has not kept to the subject. He will allow me, in the first place, to tell him that I have for several years been well acquainted with the effects of imperfect contacts, even between metallic substances, and have studied them at various times since the year 1856. I sent you the analysis of these researches, which you were good enough to publish in your journal for the 10th of June; and it is because I have carefully studied these effects that I know that electrical variations, resulting from a more or less close adherence of the contacts, are more limited with metallic conductors than with imperfect ones. Therefore when I say that Reis's receiver with needles cannot reproduce speech loudly, I suppose the original transmitter of Reis to be used, and not any improved apparatus, such as those of Hunnings and Ader. It is certain that with good transmitters and a powerful battery articulate sounds can be obtained from a similar kind of receiver, and M. Ader's *speaking table*, which I have described in the two last editions of my work on the telephone (*see* p. 380 of the fourth edition, and p. 317 of the third) is a proof of this. I had even asserted this in the year 1878, at the time of my discussion with Colonel Navez, but what seems to me difficult to believe, is that this effect can be obtained with the metallic contacts employed by Reis. The question is not what can be done at the present day, but what could be done in 1863. Besides, experiment has shown M. Ader that his speaking table could only reproduce sounds at a very short distance—from one room to another, for instance.

On the other hand, while asserting that speech can scarcely be reproduced in Reis's needle receiver with his metallic contact transmitter, I will readily admit that it can be effected with this transmitter, if an improved Bell receiver be used, and if the receiver alluded to by Mr. S. Thompson, with which I am not acquainted, is under analogous conditions, I can agree with him. It would, however, still be very extraordinary that such an important discovery should not have had more publicity, and that our attention should have been called to it from America.

As to the principle of the variability of the intensity of currents with imperfect contacts when submitted to various pressures, Mr. S. Thompson will allow me to tell him that in the year 1874 I had asserted and *proved* that the actuating cause was the *variation in the closeness of the adherence* of the two contacts, and this hypothesis has been maintained lately by Mr. Thompson himself, and also demonstrated in 1879 by Mr. Barrett. But the field of electrical variations is more extended with bodies of moderate conductivity, as the effects are then due to several causes:—first, the more or less close adherence of the contacts; secondly, the amount of surface of the two conductors in contact, which is equivalent to a sectional variation; thirdly, the degree of subsidence of the molecules of the conductors in contact; fourthly, the different conditions in the gaseous medium interposed between the surfaces of contact, and, perhaps, even the various conditions of a *disruptive* discharge of the current, inappreciable to the observer, but perhaps producing an effect on the telephone. Recently experiments on these points have been undertaken by English *savants*, and I believe they help to elucidate this question, which is still obscure. But in my opinion it is certain that all these causes manifest themselves simultaneously, and to a greater or less degree according to the nature of the conductors, and the effects are more or less forcible according to whether the conductors are favourable to them or not; and this is why carbon transmitters, or those constituted of metallic ores or agglomerations of metallic filings, are the best for telephonic purposes.

TH. DU MONCEL.

Lebisey, *August 8th*, 1882.

THE POST OFFICE AND THE TELEPHONE.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—The public have read with extreme gratification that our Liberal Postmaster-General has relieved the telephone industry of the one difficulty which attended its extension, by promising to license the operations of all telephone companies.

Last winter I addressed a crowded meeting in the Theatre of the Society of Arts, under the presidentship of the Right Honourable E. P. Bouverie, on the subject of this industry and the great public benefits which would accrue from the wide extension of telephone exchanges throughout the land, at rates of subscription which would bring it within the reach of every one for social as well as commercial purposes, and still return a handsome profit to the undertakers.

In noticing the slow progress the use of the telephone exchange has made in the United Kingdom, in comparison with other countries, I showed the audience how the construction, maintenance, and working of the systems should be adapted to the wants and prejudices of the public at large, and how necessary it was to commence operations, so as to avoid the natural dislike of the community to the unsightliness and inconvenience of the ordinary poles and wires of our telegraphs, and, that the true way to overcome these obstacles was to enlist the public of each locality in the establishment of telephony for the use and convenience of the majority.

The application of this simple and naturally cheap help to the daily transactions of life is an infinitely easier matter than that of electric lighting, and yet we see the public investing deeply in those industries and almost neglecting the telephone industry altogether.

It can be easily shown that the establishment of a telephone exchange of one hundred subscribers, within a square mile, and costing each subscriber not more than 6d. a day, will safely pay an interest of more than 15 per cent. to the capitalist, after providing 65 per cent. for working, maintenance, and renewal expenses, and that every further extension in the same area will largely increase that return.

It is to be reaped in any part of the kingdom in which 100 persons, able and willing to subscribe 6d. a day for the convenience, can be found within a square mile. All experience in other countries shows that once introduced it spreads rapidly, and once established, it becomes a necessity, like water, light, &c.

The money value of the saving in labour to the community is far in excess in proportion to the value of the plant, in comparison with the saving arising for like reasons out of the use of the State telegraphs, because the average traffic is far more and the cost of manipulators is saved, as the public speaks its own messages.

A bill somewhat on the same lines as that for electric lighting would smooth any difficulties which are still encountered in the extension of the telephone systems, and

by cheapening the first cost to the companies undertaking the work, would also cheapen the service to the public. Bills of this kind have generally to be promoted by industries. The public cannot do better than support by their adhesion the companies which now appear to be springing up, with the object of extending true, cheap telephony. The ultimate reward to good work and good management is so secure, if the companies are established and worked on sound financial principles, that there is no industry which can offer fewer risks to the investor.

The objection to the public use of the fundamental principles of the invention, raised by the owners of patents, can never stand before the fair test of a scientific investigation.

All monopolies must fall immediately the public becomes aware that they are standing in the way of a great social necessity.

C. E. WEBBER,
President Society Telegraph Engineers
and of Electricians.

August 11th, 1882.

IMPROVEMENTS IN ACCUMULATORS.

To the Editors of THE ELECTRICAL REVIEW.

DEAR SIRS,—In the number of your interesting Review for July 29th you have described some experiments made with modified Faure accumulators, the results of which have been published in the *Annales de l'Electricité*.

In reproducing the general results alone, you accompany them with guarded remarks based on an inexact and incomplete understanding of acquired facts, which I can only explain by a bad translation.

You will allow me therefore, I trust, for the edification of your readers, to put the matter in its true light.

The following, to begin with, are the results of two published experiments.

A. An accumulator containing 3·145 kilogrammes of *minium* and 4 kilogrammes of lead was taken.

During	15 m.	a current of	10 amp.,	that is	2·5	amp. hrs.
,, the next	2 hrs.	,,	9½ ,,	,,	19·	,,
,, ,,	8 hrs. 15 m.	,,	9 ,,	,,	74·25	,,
,, ,,	15 m.	,,	6 ,,	,,	1·50	,,
	10 hrs. 45 m.		Total ...	...	97·25	

Or a current of 9 ampères during 10 hours.

In explaining the formula $\text{Tr} = \frac{\text{E I}}{\text{g}}$ we have

$$\text{Tr} = \frac{2{\cdot}15 \times 9}{10} = 1{\cdot}935$$ kilogrammètres per second, from which 1·935 × 36,000 = 69,660 kilogrammètres, which makes 22,149 kilogrammètres per kilogramme of active matter (3·145 k. of minium).

B. An accumulator containing 8·100 k. of minium and 8·800 k. of lead was taken.

During	6 h. 30 m.,	a current of	13·33	amp.,	that is	86·64	amp. h.
,, next	9 h. 30 m.	,,	13·	,,	,,	123·50	,,
,, ,,	45 m.	,,	12·	,,	,,	9·	,,
,, ,,	15 m.	,,	11·	,,	,,	2·75	,,
,, ,,	45 m.	,,	10·	,,	,,	7·50	,,
,, ,,	15 m.	,,	9·	,,	,,	2·25	,,
,, ,,	30 m.	,,	8·	,,	,,	4·	,,
	19 h. 10 m.*			Total ...	...	235·64	

Or a current of 13 ampères during nineteen hours.

We have by the following formula :—

$$\text{Tr} = \frac{2{\cdot}15 \times 13}{10} = 2{\cdot}795$$ kilogrammètres per second, from which 2·795 × 68,400 = 191·178 kilogrammètres, or 11,371 kilogrammètres per kilogramme of minium and of lead, or 23,600 kilogrammètres per kilogramme of active matter (8·100 k. of minium).

Such are the figures.

I will add that the measures of the intensity of the current were taken every 15 minutes by the help of a Marcel Deprez galvanometer.

You say that in the preceding calculations no account is taken of the weights of the liquid nor of the holder, and you leave it to be believed that I compare figures thus obtained with those given by other experiments calculated on the total weights of the apparatus, that is, 4,000 kilogrammètres per *kilogramme of the accumulator*. Now I have explained that the results of the experiments of Sir William Thomson show that 5,000 *kilogrammètres per kilogramme of lead and of plumbic matter* can be stored.

This figure of 5,000 kilogrammètres is not an exaggeration, it is even below the truth if you accept the published results of Sir William Thomson in the *Times* of June 9th, 1881. Sir William Thomson states in effect that he had obtained from an accumulator weighing 8·500 k. a quantity of work equal to 260,000 foot pounds, or 35,900 kilogrammètres. I have tried an apparatus of the same pattern and of the same formation, containing 5·700 k. of plumbic matter, that is to say, of lead forming the supporting plates, and the minium; the weight of this last was about 3·500 k. after its transformation into *spongy lead* on one of the plates and peroxyde of lead on the other, this constitutes the *active matter*.

From these figures it results that Sir William Thomson has extracted 6,300 kilogrammètres per kilogramme from the plumbic matter, or 10,250 *kilogrammètres per kilogramme of active matter*, or 4,220 kilogrammètres per kilogramme of dead weight.

This method of giving the results offers the advantage of showing that some progress has resulted other than in the capacity of storage of active matter, in seeking to diminish dead weight.

Sir William Thomson does not give any details of his experiments, which must be accepted with a certain amount of reserve. Up to the present his figures have not been contested; interpreted as I take them they will certainly make those which result from my experiments appear to you less fantastic.

Further still, you make me say that "the discharge operates with a constant electromotive force of 2·15 volts," which is not exactly the case. You add, "The intensity of the current through an unknown resistance at the commencement of the discharge is 13·33 ampères, whilst it is no more than 8 ampères at the conclusion." What is not quite correct is your way of making me say that the electromotive force 2·15 volts is constant. You have made me to say, with as much truth, that the intensity of the current was *constant*, and that the action of the *pesanteur* at Paris is equal to 10. The truth is that I have simply sought to approximate the mean figures, which is not exactly the same thing. It is true, however, that the current varied from 13·33 to 8 ampères; but the duration of the discharge having been 19 hours 10 minutes, and the intensity of the current having taken only 3 hours to fall from 13 to 8 ampères, by neglecting this quantity and keeping 2·15 as the electromotive force for the remainder, the amount of energy stored is still more than 20,300 kilogrammètres per kilogramme of active matter.

In order to measure the electromotive force I had only at my disposal a fine wire Marcel Deprez galvanometer, which was insufficient for exact measurements; I was obliged, therefore, to have recourse to the figures resulting from previous experiments. Now, I read in the same number of the *Annales de l'Electricité*, in the column next to those where are the figures under discussion, that the constant relative electromotive force of the Faure battery is 2·15 volts for the 6·50 k. size. The value is that of M. E. Reynier.

In the number for May, 1881, of *L'Electricien*, page 75, M. Niaudet says that the result of *careful* measurements of the electromotive force of the Faure accumulator shows the value to be 2·25 volts; and he gives figures for evaluating the work in kilogrammètres by the formula—

$$\text{Tr} = \frac{\text{E I}}{\text{g}}$$

M. G. Planté, in his "Recherches sur l'Electricité," page 75, says that when a single secondary Planté couple, well formed, is worked with, the greater part of the numbers found for the electromotive force are between 1·45 and 1·50, the Bunsen being taken as the unit. Now, as the electromotive force of a Bunsen is between 1·89 and 1·96 volts—(Niaudet gives 1·734)—therefore if we take the value of the Planté to be 1·45 of the Bunsen, and the latter to be 1·80 volts, then this gives 2·61 volts as the electromotive force of the Planté (2·51 according to M. Niaudet).

In the same number of the ELECTRICAL REVIEW for 29th

---

* Our Correspondent's figures only make 18¼ hours.

July, page 64, there is an article extracted from *Nature*, and entitled "The Chemistry of the Planté and Faure Cell," in which it is stated that the initial electromotive force of a battery freshly charged varies from 2·21 to 2·31 volts, the mean value being taken as 2·25; but after thirty minutes' rest, or of discharge it becomes reduced to 2 volts. This fall is attributed to the liberation of the gas accumulated on the electrodes. In another experiment the electromotive force fell from 2·25 to 1·92 in forty-five minutes, and recovered to 1·96 after thirty minutes' rest, and to 1·98 after eight hours' rest, but the internal resistance was in this case ·58 ohms. Is this resistance that of the whole battery or of a single element? In this last case it is important to know in what condition was the element in question, since the resistance of the accumulator in good condition has been found to vary from ·006 to ·040 ohms during the discharge.

Finally, the experiments of MM. Allard, Le Blanc, Joubert, Potier, and Tresca, have proved a diminution of electromotive force from 2·165 to 2·057 volts, whilst the current falls from 16·37 to 11·49 ampères. In these experiments a sufficient time elapses between the end of the charge and the commencement of the discharge.

In these figures it appears to follow that the constants of the Faure battery are not the same for all the elements, and that they differ according to the state of each. Well, do you not think that it is possible to make these constants much more uniform by regulating the chemical reactions and to increase the storage capacity by facilitating and rendering these reactions more complete?

Why cannot the accumulators be improved as regards the minium? Is it extraordinary to expect to see double the power in the active material in these elements? M. Faure has written somewhere that it is scarcely possible to obtain the tenth part of what the minium can give; there is still, therefore, some margin, and since the accumulator is perfectible, why cannot it be perfected like the steam-engine, for example? The consumption of fuel in the latter has been reduced from 8 or 10 kilogrammes per horse-power per hour down to less than 1 kilogramme. If, now, you wish to be astonished by the reality of the progress already accomplished in the construction of the Faure battery, then, according to ordinary principles, before the application of the active matter on the plates, simply intimately mix with it a very porous and finely divided substance, and you will certainly be less incredulous when you see it work.

I venture to hope that you will not find this letter, foreign to all industrial speculation, too long to be inserted in your next number.

I am, dear Sirs, yours faithfully,

C. BLANCHART.

THE CITY AND GUILDS OF LONDON INSTITUTE TECHNOLOGICAL EXAMINATIONS, 1882.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Your readers are, no doubt, much indebted to your correspondent, "Fareham," for having, in a recent issue of your paper, brought under their notice the decisions of the examiners in the electrical subjects of these examinations. But while they will also certainly join with him in acknowledging the desirability of having theoretical excellency supported by practical ability, I am confident they will lend no approval to his eminently Quixotic tilt against the scope of the work of this useful organisation. The machinery and work of the City and Guilds of London Institute are subject to the two considerations which rule as regards material appliances, viz., practicability in the first place, and then financial economy. Let "Fareham" give a little careful thought to the matter, as others have done, and he will find that the elaboration and consequent expense required to conduct these examinations on the lines laid down by him would altogether fail to yield a commensurate advantage.

But, after all, it may be that "Fareham" is afflicting himself with needless concern. I may be mistaken, but I understand those only are eligible for examination in any industry who are practically engaged in that special industry. [Mo]reover, the examiner in telegraphy has said in effect (I [quot]e from recollection,) that he had no difficulty in esti[mating] from the papers the extent of the respective students' practical acquaintance with the subject. And in all likelihood the same will hold with the other examiners.

In support of his somewhat vehemently expressed dictum that paper examinations are utterly useless, "Fareham" instances a circumstance, but the inexactness of the narrated details makes impossible the formation of any opinion from them. A is a telegraph testing clerk, we are told; B, a young operator. Five years ago A obtained in magnetism and electricity a "first-class certificate"—whether elementary, or advanced, or honours, "Fareham" leaves to speculating theorists to discover. However, A devotes the greater portion of his time during the five years following to the study of technical telegraphy, and in so doing must, your readers will presume, pay close and enthusiastic regard to the results of invention and research chronicled periodically in the scientific press throughout that period. Yet "Fareham" asserts of this devoted student, who is taken to be typical of practical men, that being so destitute of ability to express himself upon paper, in a recent technological examination in telegraphy, he is signally out-distanced by B, who has attended some class for only six months. The statements in the previous sentence are remarkably strange, in fact, scarcely credible, and since "Fareham" has built his entire argument upon this case, possibly he will not object to make a second and exhaustive inquiry into the facts, and communicate the result to your paper. According to "Fareham," B obtains an honours place, a position understood to be attainable only by those who have at least *some* knowledge of dynamics, chemistry, and mathematics, in addition to a creditable acquaintance with electrical phenomena and laws, and with practical telegraphy.

As regards A's discomfiture, many will in the meantime, like myself, draw the inference that his capacity and his industry are alike microscopic, and that as for the practical testing duties devolving upon him they are likely to be of an exceedingly common and simple order.

A. C. S.

College of Science and Arts,
Glasgow, *August 14th*, 1882.

THE TELEPHONE.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—The suggestion made by your correspondent, "Justice," that "the too easily gulled British public should consult scientific publications instead of financial newspapers when it is asked to subscribe to schemes which embrace the development of scientific inventions," seems to be good common-sense advice, and, for the benefit of the too oft self-deluded public, I send you a few remarks and official statistics in regard to the numerous British patents for telephones and transmitters.

The first British patent for a speaking telephone was that issued to A. G. Bell, No. 4765, December 9, 1876, which, however, was greatly modified by a disclaimer on February 13, 1878.

This patent has undergone critical examination in two courts, viz., at Edinburgh before Lord M'Laren in February last, and at London before Mr. Justice Fry in May last. To those two decisions we are indebted for a clear and concise judicial description of Bell's patent, based upon the evidence given by the most eminent electricians in Great Britain. This decision is of the highest importance to investors in telephone property, whether it be in telephone companies or in telephone patents, because it is so clear and simple that any one possessed of common sense can judge for himself as to what constitutes Bell's patent and what constitutes an infringement of Bell's patent.

Bell's original patent contained eighteen claims, the disclaimer reduced them to eight; of these, the 6th, 7th, and 8th, contain the soul of the patent, which is the same in those three claims.

The 6th claim is, "The combination in the manner described in the fourth and fifth plans, but subject always to the disclaiming notes, of an electro-magnet, with a plate of iron or steel or other material capable of inductive action, which can be thrown into vibration by the movement of surrounding air, or by the attraction of a magnet."

In the suit of the United Telephone Company against Harrison, Cox-Walker, the latter set up for defence the prior publication of a description of Reis's instrument of 1862. In the Reis instrument there was, "facing the poles of the electro-magnet, an armature attached to a broad, thin, but light plate."

As Bell's claim was for a plate of any material capable of inductive action in combination with an electro-magnet, the eminent counsel for the United Telephone Company (Mr. Aston, Q.C.,) said, "The whole case turned on the question of whether or not there was a publication of a receiver having a plate armature prior to December, 1876." He contended that the broad, thin, light plate of Reis, which counsel called a "bar" or "tongue," "was in no sense a plate armature; and as the plate armature was essential in Bell, and the 'bar' used in Reis was in no sense a plate armature, and therefore no anticipation of Bell's."

The plate armature in Bell's is described by Sir William Thomson as an iron or steel disc fixed all around its edges. Mr. Aston insisted "particularly in the fundamental distinction between the 'bar' in Reis and the plate armature in the Bell."

Mr. Justice Fry describes the plate armature of Bell as "a metal disc resting, as regards its circumference, on the wooden case;" and he further says that "the armature in Reis was not a disc at all, it was not a plate at all, but it was a beam or solid bar;" and he decided that the "Reis receiver was not in anticipation of Bell's receiver."

It is, then, clearly established that in a telephone receiver the use of a disc of a material capable of inductive action fixed all around its edges is secured to Bell; and it is further established that a "tongue" or "bar," as in the Reis instrument, is outside of Bell's patent.

I submit two complete lists of British patents for telephone receivers. The first contains those patents in which a disc capable of inductive action is used in combination with a magnet or electro-magnet. The second list contains those in which there is not used a disc capable of inductive action. Let inventors judge for themselves.

List of British patents for telephone receivers in which a disc capable of inductive action is used in combination with a magnet:—

If the above be acceptable I shall continue the report of patents of telephone receivers for 1880-81, and for transmitters from Bell's of 1876.

Yours, &c.,

COMMON SENSE.

[We shall be glad to publish the further communication promised by our correspondent.—EDS. ELEC. REV.]

THE ELECTRIC LIGHTING BILL.

HOUSE OF COMMONS, Monday, *August 14th.*

ON the motion to consider the House of Lords' amendments to the Electric Lighting Bill,

Sir John Jenkins protested against the amendment extending from 15 to 21 years the duration of a licence before a local authority could compulsorily acquire an installation without compensation for retrospective or prospective profits.

Mr. Dillwyn thought 21 years a very long period, and hoped the President of the Board of Trade would adhere to the compromise he had introduced into the Bill.

Mr. Chamberlain said the hon. member for Swansea was correct in his statement of the circumstances under which the compromise of 15 years was arrived at. When he recommended 15 years to the Select Committee, and when the question was last discussed in the House, he was of opinion that that compromise was a fair one, but since then further information had been put before him which had made a difference in his opinion, and which he thought might perhaps also alter the opinion of his hon. friend. When the matter was discussed before the select committee it was certainly believed by that committee that in the present experimental stage of electric lighting there would be no great expenditure of capital, and that if it was intended to make an experiment by lighting a few houses, a street, or some small district, a monopoly of 15 years would be quite sufficient to remunerate the promoters for their outlay. But already, in the short time during which the matter had been under consideration, very great advancement had been made in electric lighting, and now it seemed probable that large instalments would in some cases be made, involving an outlay of hundreds of thousands of pounds, and it did not seem to him that 14 or 15 years would in all cases be long enough to justify a great outlay of capital. If companies were restricted to the shorter period they would not be inclined to invest their capital, and so that development would not be given to electric lighting which was so desirable. For these reasons he had been willing to reconsider his first opinion. An amendment had been proposed in the other House suggesting that the period during which companies should be empowered to supply electric light before being subject to be bought up under the purchase clause should be extended to 21 years. He had objected to that because it would involve the granting of 21 years in the case of small installations as well as large ones, and so he had secured an amendment to that amendment; and in the Bill now came before them the period was a maximum of 21 years, giving the local authorities, in all cases where applications were made to them for permission to experiment, the power of coming to an agreement with the applicants whereby a shorter term might be consented to. Under these circumstances he hoped no grievance would result; and he believed the clause would be found to work satisfactorily, and at the same time prevent a monopoly being set up which would be dangerous to public interests.

Sir John Lubbock said the power which the local authorities would have of purchasing an installation was a very different thing from a monopoly. When the term had been fixed at 15 years, the chairmen of the Edison and the Swan companies protested against it, saying they were not satisfied. He agreed with the right hon. gentleman, that in a case where a quarter or half a million of money came to be invested, and the company was liable to be bought up in 15 years, the term was too short and should be extended. No doubt the hon. member for Swansea was right in saying that the electric lighting was still in an experimental stage, but the fact that it could be carried on successfully and generally had been established by the experience attained at Holborn Viaduct and other places; and the only question now to be decided was, Which was the best system? He hoped the House would agree to the amendment.

The amendments suggested by the House of Lords were then agreed to. Among them were the following:—

In p. 2, l. 29, after "given," insert as a new sub-section:—"A licence may, subject to the provisions of this Act, be granted to a local authority, authorising them to supply electricity within any area, although the same, or some part thereof, may not be included within their own district."

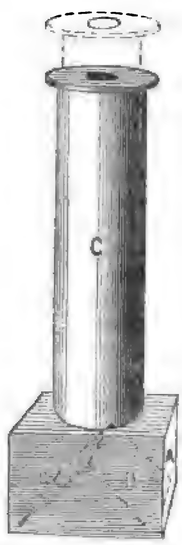
In p. 3, l. 17, after "provisions," insert as a new sub-section:—"No provisional order shall authorise the supply of any electricity by any undertakers within the district of any local authority (not being themselves the undertakers) unless notice that such provisional order has been, or is intended to be, applied for has been given to such local authority, in such manner as the Board of Trade may direct or approve, on or before the 1st day of July in the year in which such application is made; provided that, in the case of any application made during the present year, such notice shall be deemed to have been given in due time if the same is given within one month after the passing of this Act."

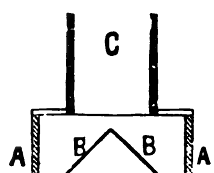
ELECTRIC LIGHT IN THE EDGWARE ROAD.—An installation of 50 incandescent lamps on the Swan system has just been completed for lighting the premises of Mr. Bouron, provision merchant, at 279, Edgware Road. The lights, which are in use every evening, are a great success and are worked by a small gas-engine on the premises. A great saving is expected in the quantity of provisions usually spoiled owing to the absence of heat in using these lights, the shop therefore being kept cool. The work has been carried out by Messrs. Edmundson & Co., of 19, Great George Street, Westminster, agents for the Swan system, who are engaged also in some much larger installations.

NOTES.

Errata.—In the article on the lighting of the Comptoir d'Escompte in our last issue, for "Corrozer" read "Corroyer"; for "each cubic metre" of solution read "for two cubic metres"; and for "ten carbons of ten millimetres" read "with carbons of ten millimetres."

A Pocket Photometer.—This little instrument, which will doubtless be of service to all who are engaged in electric or other kinds of lighting, has been devised by Mr. Robert Sabine for the purpose of being conveniently carried about in the pocket, so as to be at all times accessible for approximately measuring the respective illuminating power of different lights. Its construction is based on the plan proposed by Ritchie, which we illustrated and described in an article on Photometers in the Electrical Review of April 8th. In the rectangular base of this little instrument—the





two ends of which are closed by squares of opal glass, A, A, cut from the same sheet—is a prism, B, B, made up of two plane mirrors fixed at right angles. The draw-tube containing the eye piece, in which is inserted a small lens, is movable in the outside tube, C, attached to the base, and a correct focus may therefore be obtained and the mirrors clearly seen from a very short distance,—about 4 inches. Were it not for the introduction of this lens, the tube down which the observer looks would have to be considerably longer in order to obtain a clear view of the plane mirrors. As the operation of using distance photometers is so well known, it is needless to refer to it. Any one could construct such an instrument for his own use at the expense of 2s. 6d. or 3s. The sketch sufficiently explains all the details of its construction. We may add that we believe Messrs. Elliott Bros., the well-known electrical instrument makers, will shortly be able to supply these little photometers to those desirous of becoming possessed of such a useful and handy means of measuring any kind of light.

The Bewildering Higgs.—In our brief notice of this matter last week we omitted to state that which is, however, already well known in electrical circles, viz., that the legal action taken by Messrs. Siemens Brothers against the subject of our note was dismissed. The *New York Times* of June 16th, after devoting some space to the attainments of Dr. Paget Higgs, says:

He came here under the auspices of S. F. Van Choate, of Boston, Mass., to do some work for the American Cable Company of that city, which required the highest mathematical and electrical knowledge. He was very highly recommended (?) by Siemens the famous English electrician, and the work he was engaged to do was performed in a satisfactory manner. . . . . In the intervals between his work for the cable people he unfolded, slowly and cleverly, the details of a wonderful contrivance he had invented for the transmission of power by electricity, which was stated to be in successful operation in Wales. . . . . . A fortune seemed to be within his grasp, and yet he did not seem anxious to reach out and take it. Mr. Van Choate was fascinated with the brilliant future that seemed to be open to any one who could induce Higgs to remain on this side of the Atlantic and develop his plans here. He forgot in his enthusiasm what he well knew, that Higgs' coming to this country was under suspicious circumstances. . . . A company was organised in Boston through the efforts of Mr. Van Choate and Russell A. Ballou. The capital, on paper, was 5,000,000 dols.; the object, to develop Mr. Higgs' plan for an economic electric light, for the electrical transmission of power, and the construction of storage batteries. Mr. Higgs began the development of his theories and ideas, made applications for patents, and frequently reported progress in the most glowing terms. He is said to have received 10,000 dols. for his alleged services in that city. A date was finally fixed for the exhibition of one of his inventions, and the promise was made that if his machine for the transmission of power was successful he should receive 50,000 dols. in cash, and 1,300,000 dols. in stock of the proposed company for his patents and services. He made over all his applications for patents, and, after the manner of Keely, boasted of the probabilities and possibilities of his inventions. The day before the date fixed for the exhibition, Dr. Paget Higgs left Boston, leaving behind him a message that he had left the city because of his father's sudden death. Then he came to New York City, and those Bostonians who invested in his promises have not seen him since, though at intervals he wrote to his friends there informing them of the progress he was making. They trusted him, and so far as can be ascertained sunk more money in the doctor's abysmal pocket. When Dr. Paget Higgs came to New York City he established himself on the parlour floor of a house on Twenty-third Street, facing Madison Square, and threw out his lines for a new lot of fish, so to speak. . . . A company, known as the Higgs Electric Light and Power Company was organised, but as a quarrel ensued between Mr. Higgs and the other projectors of the company, which was to have a capital of 500,000 dols., Mr. Higgs refused to go ahead and perfect his inventions; the company found no further reason for their existence on paper, and went out of business without having done any business. . . . . The inadaptibility of Dr. Higgs to manage the business of the proposed company was known, and one of the gentlemen interested in the doctor and his plans induced a friend, Frederick W. Harne, then superintendent of a slate quarry at Bangor, Penn., to accept the business management of the proposed new company. . . . . He went to Chicago to prepare the way for the organisation and work of the new company. After some trouble he succeeded in securing a plant for the proposed electric light in the Tremont House in that city, and made a contract to light the hotel with Higgs' light. Dr. Higgs was established in a laboratory at No. 63, Kent Street, Greenpoint, Long Island, and began work on the development of his electric light. . . . . All this was about the 1st of January last. About that time, or just before it, he had sold and shipped two electric lights to Montreal, Canada, neither of which would work, a fact not known until comparatively recently, however. About the middle of January he exhibited at Greenpoint, to Mr. Harne and others, a light which he claimed as his own, but which, it has been since proved, was a Wood's lamp run by a Wood's dynamo-machine. . . . . But to return to the Chicago enterprise. Mr. Harne went to that city, established his plant, bought his engines, and on the 15th of February, having paid to Dr. Higgs 700 dols. for dynamo-machines, lamps, &c., after a delay of a week a couple of dynamo-machines arrived in Chicago; but, as Mr. Harne was a novice in the electric lighting business, he did not discover the fact that they were of the Wood make. . . . The complete failure of the scheme induced Mr. Harne to make an investigation into Higgs' antecedents, and he accidentally heard of Mr. Van Choate, in Boston, as having a knowledge of Higgs and his antecedents. In response to a letter of inquiry Mr. Van Choate wrote from Boston, under date of April 2nd, as follows:—

"I imported him into this country a little over two years ago, and for which I am very sorry. . . . . So far as my dealings with him go, I have found him to be the greatest liar, scamp, and fraud of all the men I ever heard of during my thirty years' business with people. He has no capability for inventing anything but lies." . . . . Higgs shipped his wife to England on an Inman steamer as soon as the disclosures of his true character seemed imminent, and he followed her on the *Alaska*, which left this port on May 31st. The various investors were badly left, and the mystery of his inventions departed with him. . . . . The case of Dr. Higgs is a very peculiar one, there seeming to be wholly unnecessary prostitution of undoubted talents. Why this was done does not wholly appear, for he does not seem to have obtained money from his dupes for his personal benefit, and such money as he did obtain was expended in the prosecution of electrical experiments. . . . . It has recently been ascertained that for some unprofessional practices Dr. Higgs was expelled from the Institute of Civil Engineers in England. During his stay here it has been ascertained that the only storage battery that he invented was the previously invented Sellon and Volckmar storage battery; the only dynamo-machine that has worked, the Wood machine; and the only electric lamp, one that will not burn in series and is not a remarkable success as a single light. So far as can be ascertained, the money he has been able to [illegible] from Americans will not aggregate more than 20,000 dols., unless [illegible] losses of the Philadelphians are larger than the 5,000 dols. at which they are estimated. That amount also represents the sum he obtaine[illegible] in this city.

The Central Laboratory of Electricity in Pari[illegible] —The French Minister of Posts and Telegraphs has a[illegible] pointed a special commission to study the organisation [illegible] the working of the Central Laboratory of Electricity. [illegible] commission is composed of the following gentlemen:—

Songeon, president du conseil municipal de Paris; D[illegible] member de l'Institut, secrétaire perpétuel de l'Acadé[illegible] Sciences; Alphand, directeur des travaux de Paris [illegible] member de l'Institut; Le Colonel Perrier, m[illegible]

l'Institut et du Bureau des Longitudes; Bréguet, membre de l'Institut et du Bureau des Longitudes; Tisserand, conseiller d'Etat, directeur au Ministère de l'Agriculture; Mascart, professor au Collège de France, directeur du Bureau Central Météorologique; Becquerel, ingénieur ordinaire des ponts et chaussées, répétiteur de physique à l'Ecole Polytechnique; Fournier, capitaine de frégate, attaché à l'état-major du Ministère de la Marine et des Colonies; Penel, commandant du génie, attaché à l'état-major général du Ministre de la Guerre; Mercadier, ingénieur-electricien, directeur des études à l'Ecole Polytechnique; Bergon, directeur du matériel et de la construction au Ministère des Postes et des Télégraphes; Blavier, directeur de l'Ecole Supérieure de Télégraphie au Ministère des Postes et des Télégraphes; Boussac, inspecteur-général chargé des services du contrôle au Ministère des Postes et des Télégraphes; Caël, directeur-ingénieur des Télégraphes; Georges Cochéry, directeur du cabinet et du service général au Ministère des Postes et des Télégraphes; Fribourg, directeur du personnel au Ministère des Postes et des Télégraphes; Raynaud, ingénieur des Télégraphes; Trotin, ingénieur des Télégraphes.

Tenders for the Supply of Telegraph Material.—We read in the *Moniteur des Adjudications de l'Etat*, that the French Telegraph Administration invites tenders for the supply of the following instruments, stores, &c., the adjudication of which will take place on the 22nd inst., viz.:—

1. The supply of sending and receiving telegraph instruments divided in 16 lots, composed of 60 Hughes' instruments, 1,800 Morse receivers, 8 transmitters, 8 receivers, and 80 Wheatstone perforators, 1,400 sounders, 1,500 electric bells, 2,200 detectors.

2. The supply of additional apparatus for telegraph offices, divided in 10 lots, and composed of 1,700 Morse keys, 3,700 commutators, 800 bell pushes, 4,400 lightning protectors of various systems, 1,200 paper-wheels, 15,000 brass-screw terminal, 25,000 brass strips for table connections, 6,000 battery terminals, 10,000 ebonite case pieces (socles), 20,000 ebonite washers, and 400 oak boxes.

3. The supply of materials and chemical productions for batteries, divided in nine lots, and composed of 46,000 glass jars of various models, 60,000 porous pots, 172,000 various zinc pieces for batteries, 10,000 kilogs. of bi-oxide of manganese, 10,000 kilogs. of chlorhydrate of ammoniac, 90,000 kilogs. of sulphate of copper, 8,000 kilogs. of pounded retort carbon, 4,000 kilogs. of dextrine, 70,000 prisms of retort carbon, and 3,000 kilogs. of copper wire of ·08 diameter.

Further particulars may be obtained from the Administration, 103, Rue de Grenelle, Saint Germain, Paris.

The Maxim Incandescent Electric Lamp.—We believe that this light has been withdrawn from the General Post-office at Glasgow, amid universal grumbling on the part of the men. We hear various rumours to account for this, and from what we can understand the matter is apparently a personal one. The blame however will doubtless be cast upon the electric light in some form or other.

The Electric Lighting of Theatres at Paris.—After the recent experiments of electric lighting made at the Théâtre des Variétés, M. Bertrand has determined to light his house for a whole season, from September, 1882, until June, 1883, by incandescent lamps. After this long trial, electric lighting will be used permanently or discontinued. The other directors of the theatre await the results of this innovation before making a decision. Meanwhile, the manager of the Eden Theatre, at present in course of construction, has determined to adopt electricity for the complete illumination of the theatre, making use of the voltaic arc and incandescence, by means of Maxim lamps and Kabath accumulators, charged from the necessary apparatus placed in the basement of the Eden. The experiments in preparation are, therefore, very interesting, and we will follow their development carefully.

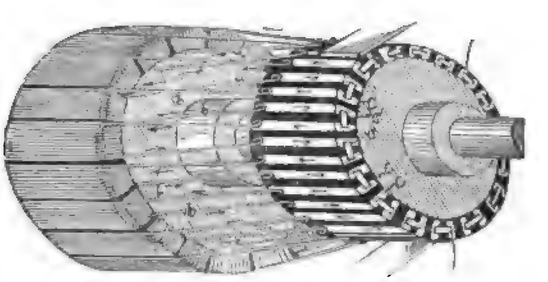
The Electric Light at Liverpool.—We hear that the Edison electric light, to which we alluded last week, has been used with great success at the Adelphi Hotel. Three large burners in the great ball-room, and another in the hall, have shed a brilliant radiance on the illustrious guests who have been in the city recently in connection with the International Law Conference.

The Brush Midland Electric Light and Power Company, Limited.—This Company has received an order to light up the factory of Messrs. Birkin Brothers, the well-known lace manufacturers of Nottingham, with Brush arc and Lane-Fox incandescent lamps.

At Gainsborough the same company, in compliance with the request of a number of the leading inhabitants of that town, who undertook to defray all expenses, has during the past fortnight very successfully illuminated the market-place with Brush arc lamps, and also exhibited Lane-Fox incandescent lamps in the shop of one of the principal tradesmen. Both the arc and incandescent lamps were run on a single circuit from the same machine, and were proved to be under perfect control. Numerous applications for electric lights—especially for the Lane-Fox lamps—have, we understand, been received by the company.

The Cost of the Electric Light at Edinburgh.—The abstract of the Edinburgh Police accounts, just issued, shows that for the "experimental electric lighting" of the North Bridge, Waverley Bridge, and Princes Street, on the "Brush" system, from the 25th August, 1881, to the 2nd January, 1882, the city paid the sum of £1,181 4s. 8d.; and for a trial of the "Crompton" at Holyrood Palace, August 25th, to September 8th, £57 13s. 7d. Expenses of deputations to London bring up the total cost to £1,265 1s. 3d. The sum of these experiments is made up as follows:—Fitting up engine-house, electrical machines, &c., £115 0s. 6d.; Furnishings to engine-house, machinery, coals, and firewood, £170 15s. 9d.; Wages of watchman, and attendants at machines and lamps, £39 16s. 3d.; Lamp pillars and bases (pillars, £209; stone bases, £62 8s.; mason work at lamps, £10 6s. 8d.), £281 14s. 8d.; Electric lighting (the Anglo-American Brush Electric Light Corporation, Limited, 25th August, to 30th November, 1881, £389 10s.; the Scottish Brush Electric Light and Power Company, Limited, 3rd December, 1881, to 2nd January, 1882, £184 7s. 6d), £573 17s. 6d. Total, £1,181 4s. 8d. At Holyrood: Fitting up lamp poles, £17 13s. 7d.; The Crompton Electric Lighting Company, for electric lighting, 25th August to 8th September, 1881, £40. Total, £57 13. 7d. General Expenses: Expenses of deputations to London on experimental electric lighting, May and June, 1881, £26 3s. Total cost, £1,265 1s. 3d.

Commutator for Dynamo-Electric Machines.—Patent No. 261,520. Filed in the United States of America Patent Office, February 15th, 1882.—By R. Edward Ball.



Claim.—1. An armature for dynamo-electric machines, having each end of every bobbin thereof connected to a separate block in the commutator ring and such blocks coupled together in pairs, so that a current generated in one of said bobbins must pass to and through a pair of commutator-blocks before passing to a succeeding bobbin, substantially as shown and described.

2. In combination with an armature of a dynamo-electric machine, a commutator therefor having twice as many blocks as there are bobbins or sections on the armature-ring, so as to provide for each end of every such section being connected to a separate commutator-block, such blocks being coupled in pairs, substantially as shown and described.

3. An armature for dynamo-electric machines, the bobbins or sections whereof are disconnected from each other, each end of every bobbin being connected to a separate block in the commutator, such blocks being coupled together in pairs, and thereby forming an indirect connection for said bobbins, substantially as shown and described.

THE EDISON LIGHT IN ITALY.—We have received notice that Mr. Shepherd, the agent of the Edison Company in Italy, has succeeded in forming a syndicate of the principal bankers in Milan for the purpose of working the Edison patents in Italy. Mr. Shepherd remains with them as agent-general. This gentleman has just been lighting up a portion of Udine with the Edison light, which has proved such a success that he is preparing a contract for lighting the whole of the city. The motive force will be supplied by the River Ledra. The cities of Mortara, Pistoja, Faenza, Fano, Arezzo, Schio, and several others are also to be lighted by this system, and in Milan the theatre Santa Radegonda has been purchased for a lighting station, and part of La Scala theatre will be illuminated during the Carnival from it, and the principal shopkeepers have ordered their shops to be lighted—one firm alone having ordered 1,200 lamps.

THE COST OF THE ELECTRIC LIGHT.—We notice that Lieutenant-Colonel Festing reports that the substitution of electric lighting, by the aid of two machines driven by one engine, in the place of gas, at the South Kensington Museum, has resulted in a saving in the working expenses at the rate of nearly £750 a year, or more than £23 per annum for each lamp.

COPYRIGHT AND ELECTRIC LIGHT COMPANIES.—A motion was made in the action of "The London and Provincial Electric Lighting and Power Generating Company (Limited) *v.* The West Middlesex Electric Lighting Company (Limited)," to restrain the publication of a prospectus which the plaintiffs alleged was a copy of one which they had issued, and in which they had copyright rights. Mr. Ribton, for the plaintiffs, said since the matter was last before Mr. Justice Chitty the defendants had filed an affidavit stating that they had discontinued the issue of the prospectus in question, and had no intention of reissuing it. Under these circumstances, he asked that the motion should stand over until the second motion day in November. Mr. Marten, Q.C., acquiesced in the suggestion, and the motion, without prejudice, stands over accordingly.

THE SCOTTISH BRUSH ELECTRIC LIGHT AND POWER COMPANY (LIMITED) IN LIQUIDATION.—Intimation is given that all claims against this company must be lodged, duly vouched, with Mr. Jas. A. Molleson, 5, North St. David Street, Edinburgh, on or before Wednesday, the 23rd inst.

TELEGRAM FORMS.—F. H., in a letter to the *Times*, suggests that telegram forms should be supplied with a gummed flap, so that they might be folded and delivered sealed at the office for transmission, thereby doing away with the disadvantage of submitting the message to the perusal of the messenger.

THE NEW CABLE TO PORT SAID.—On Friday last Mr. John Pender, M.P., received a telegram from the Eastern Telegraph Company's agent announcing the completion of the new telegraph line to Port Said. The promptitude with which the work has been carried out reflects great credit on all concerned.

CENTRAL AND SOUTH AMERICAN TELEGRAPH COMPANY.—The India-rubber, Gutta-percha and Telegraph Works Company notify the receipt of a telegram from Mr. R. K. Gray, engineer-in-chief, stating that the ss. *Silvertown* had successfully completed, on the 10th inst., the San Juan del Sur-Pedro Gonzales section of the Central and South American Telegraph Company's cables.

This section was the last one to be laid, and the company's system on the West Coast of Central and South America, from Chorillos (Peru) to Salina Cruz, Tehuantepec (Mexico), is therefore now completed. On the Atlantic side the Goatzacoalcos-Vera-Cruz section connects this company's system with the Mexican Telegraph Company's cables from Vera-Cruz to Galveston, and an excellent communication is now established between the republics of Chili, Peru, Ecuador, U.S. of Columbia, Nicaragua, San Salvador, and Mexico, and the U.S. of North America. We notice in the Panama *Star and Herald* of June 22nd the following interesting items relative to the operations of the above-named company :—

"The cable steamer *Retriever* has been occupied the past two days in laying the shore end of the cable which is to place us, at an early date, in communication with the outside world. The place at which the cable was landed is about a couple of hundred yards to the eastward of the point where the road leading past the cemetery comes out on the beach. From deep water it is laid entirely in a mud or sand bottom to where it is now located. Great care was exercised in selecting the place, so that no rough or jagged rocks would be met with which would chafe or injure the cable in any way. In order to make connection with the cable now buoyed off Pacheco, one of the Pearl Islands, the *Retriever* will continue the work, laying the cable inside of Taboga and other islands, and on bottom not likely to be disturbed by vessels coming to an anchor in the port or at Taboga. The connection at Pacheco will probably be made to-day or to-morrow, when the *Retriever* will return to Taboga.

"Yesterday the connection was made between the shore section of the cable at Panama and the line buoyed off the island of Pedro Gonzales, one of the Pearl Island group. The *Silvertown* picked up the buoy behind Taboga, to which the cable was attached, and got under weigh about eight o'clock, completing the run down to the Pearl Islands and splicing the cable in a few hours from the time of starting. From the station on shore signals were exchanged with the *Silvertown* at the Pearl Islands, and to-day the line thus completed will be tested through to Lima.

"In response to the courteous invitation of Mr. J. B. Poylo a number of our principal townspeople visited the cable ships *Silvertown* and *Retriever* on Sunday, the 18th inst. The steamer *Taboguilla* took the invited guests on board in the morning, sailing about eight o'clock, calling at the island for some other guests, and arrived alongside the *Silvertown* about eleven o'clock. The two ships were lying side by side, and were gaily decorated for the occasion. A sumptuous lunch was served on board, after which dancing was indulged in until the hour for return was notified. The band of the 1st Battalion of Zapadores furnished the music for the occasion, through the kindness of General Capella Toledo, who was among the visitors. The excursion was in every respect a great success, and the ladies and gentlemen enjoying it express unqualified praise of the kindness and courtesy of the officers of the two cable ships and the other gentlemen connected with the expedition.

"The Cable ships *Retriever* and *Silvertown* will sail to-day for the Coast of Central America. They will leave the line connected as far as Panama, where it will be completed to the station in a few days and tested for any defects which may exist between here and Buenaventura. The two ships will call at San Juan del Sur in Nicaragua, and at La Libertad in Salvador, or San José de Guatemala, laying the shore sections, if the weather is good. Proceeding thence to Salinas Cruz the line will be landed and then run down along the coast, making connections with the various shore sections until the island of Pedro Gonzales is reached, where the last splice will be made and the work completed. The T. line to Panama is shorter than was originally intended. It was discovered that the depth of water across the entrance to the bay was much greater than was supposed, being in some places over 2,000 fathoms. The bottom shelves off very abruptly in places a short distance below the Pearl Islands. Lines of soundings made across the bay present some remarkable differences in depth, in some instances soundings a mile apart giving a difference of 1,000 fathoms. Soundings about 8 miles South of the Pearl Islands and North of Cape Malo gave as much as 1,800 fathoms of water, while a little further South a depth of 2,004 fathoms was reached. As the contract provided that the cable should be laid in water not over 400 fathoms deep, the original course has been abandoned, and the line of the coast has been followed, keeping to a uniform depth of water. This plan, it is believed will make the work of repairs in the future a matter of much less difficulty than if the cable had been laid in very deep water. The bottom discovered along the coast presents the same general features, and is principally a dark greenish coloured mud, in which the cable will rest with perfect safety. A vast number of specimens of this muddy deposit have been secured and chemically tested, showing, we believe, few or no traces of copper, iron pyrites, or other mineral agents whose effects on the steel sheathings of the cables are most destructive."

SUBMARINE TELEPHONE EXPERIMENTS.—Recently experiments have been conducted at Havre with a view of establishing telephonic communication between vessels and the shore. From the reports which have reached us it would appear that the operations have been attended with a large measure of success. In spite of rough weather the cable was successfully laid, and various persons and offices in the town were put in connection with the vessel anchored at nearly a mile distant from the premises of the Marie Christine Club. The Ader and Crossley instruments were used, and conversation was very distinctly maintained, notwithstanding the heavy gale, which caused the vessel to roll considerably.

This new application of the telephone will render important service to maritime commerce, since it will allow vessels arriving at a port to place themselves immediately in direct communication with owners or agents ashore. As a result of the successful experiment above referred to, a proposal to form a pontoon structure, to be moored at a distance from the land, on board of which public telephones should be placed for use by ships has already been mooted at Havre.

THE UNITED TELEPHONE COMPANY.—This company is now becoming most energetic. A circular has been sent to its various subscribers couched in these terms :—

SIR,—Will you kindly furnish us with the names of any firms, friends of yours, who are not connected with our Telephone Exchange system, so that we may put ourselves in communication with them, with a view to extend our system, in order that it may be of greater service to yourselves and to our subscribers generally ?

Your obedient servant,,

THOMAS BLAIKIE, Secretary.

The self-sacrificing motive of the company in its consideration for its present subscribers will no doubt be duly appreciated.

THE SUEZ CANAL AND TELEGRAPHIC EXTENSION.—A Lloyd's telegram from Port Said dated August 15th, 2.15 p.m., states that the Suez Canal continues free. M. de Lesseps is reported to be impeding the extension of the new telegraph system from Port Said to Suez. The laying of that portion of the line, which would form a valuable connection with our Indian system, is, therefore, for the present suspended. The Eastern Telegraph Company have permission from the Khedive and the Suez Canal Company at Paris to lay the lines ; but this is ineffectual against the obstacles put in the way of the work at the Canal by M. de Lesseps.

THE GOVERNMENT AND THE TELEPHONE.—In a letter to the *Times*, dated the 14th inst. and signed "Electrician," the writer, in referring to Mr. Fawcett's statement in Parliament, says :—

The public could scarcely imagine from this statement that the Post-office taxes the telephone companies to the extent of at least £2 for each subscriber to central office systems. This is equal in London on 2,000 subscribers to £4,000 per annum. How, in face of this fact, Mr. Fawcett can talk of free competition between the companies and the Government is simply inconceivable.

Again, under the Post-office Acts, the Government can fix their poles or wires in or on any person's premises (even in your front garden, if they like), and all the aggrieved owner can do is to claim compensation at the hands of an arbitrator. As a matter of fact, from being Governmental, the Post-office gets most of its permissions for practically nothing.

The telephone companies on the other hand, have no such powers, but must negotiate for each permit, and pay whatever is demanded, and often very extravagant the demands are. Tenants, as well as proprietors, have frequently to be settled with likewise.

Unless, therefore, the Government are prepared to surrender their tax and to give the companies the same statutory powers it is a farce to talk of free competition with the Post-office.

THE STORM ON THE 13TH OF AUGUST AT PARIS.—A violent storm broke over Paris last Sunday at four o'clock in the morning, where it has done considerable damage. In the garden of l'Elysée, the residence of the President of the Republic, the lightning has struck a tree and stripped off the bark from top to bottom. In front of the Hôtel Dieu it struck the lamp of a carriage, and reduced it to atoms without the coachman and a passenger who occupied the vehicle feeling anything. We may add to these depredations the destruction of the roof of a house and the burning down of a cart-shed. Six women occupied in a washhouse were knocked down by the storm without any injury, but in the Boulevard de Belleville a woman was dangerously burnt on the face, and was conveyed to the Hospital of Saint Louis in an alarming condition.

TELEGRAPHS IN TURKEY.—The Turkish Government has issued a new tariff for telegraph messages. According to an imperial irade, given on the proposal of the General Administration of Posts and Telegraphs, and on the advice of the State Counsel, confirmed by the Counsel of Ministers, the internal telegraph service will henceforth be managed according to the rules of the Telegraph Convention of St. Petersburg and as revised at the conference in London.

One of the principal rules of this regulation is the taxation per word, with an *appoint* of five words, which forms the price, properly called, of the telegram. The charge per word is fixed for the whole of Turkey at 20 paras for telegrams exchanged between telegraph stations situated in any one and the same province, and at 40 paras for telegrams forwarded from one province to another, either near or far off.

This new tariff realises an exceptionally favourable condition for the development of the telegraph service in Turkey.—*La Lumière Electrique.*

ON THE VARIATION OF FRICTION PRODUCED BY VOLTAIC POLARISATION.—By M. Krouchkoll.—The electromotograph of Edison has drawn the attention of physicists to a novel fact, that of the variation of friction between a metallic surface and an electrolyte when a current is passed between the two rubbing surfaces. M. Koch published in 1879 an Investigation (*Wiedemann's Annalen* 1879, p. 92), in which he shows that polarisation by oxygen alters the rubbing surface of the platinum or palladium in such a manner as to increase the friction. Polarisation by hydrogen produces, according to this author, no effect. I have resumed these experiments under different conditions and have shown that polarisation by oxygen increases the friction, whilst polarisation by hydrogen decreases it. The electromotive force of half a Daniell is sufficient to demonstrate the phenomena. The decrease of friction by negative polarisation and its augmentation by positive polarisation increase with the electromotive force displayed.—*Comptes Rendus.*

ON THE AMPLITUDE OF TELEPHONIC VIBRATIONS.—By M. G. Salet.—Every one knows that it is possible to hear through a fir-wood door of little thickness words spoken in a room otherwise entirely closed. In this case, the sonorous vibrations transmitted by the air shake synchronously the side of the wood, and this in turn transmits its motion to the external air just as a movable piston might do. This familiar experiment ought, it may seem, to have struck physicists, since it gives a proof of the sensibility of the ear. The vibrations of the wood are, indeed, very small, scarcely larger than those of the receiving membrane of a telephone when in action, but these latter are so slight that their very existence has sometimes been called in question. They exist, however, and I am about to give an idea of their amplitude. I fixed upon the iron diaphragm of a hand-telephone of Bell's system a small disc of glass, weighing 0·45 gram. Opposite this I fixed a second, yielding with the former, Newton's rings. The apparatus, as will be seen, resembles that which M. Fizeau devised for studying expansions. If we speak at the distance of five to six metres from the telephone, or if we direct against it a telephonic current produced by means of a good transmitter (that of Boettscher, for instance, which does not require the use of a battery), we see the rings lose their distinctness and disappear if the voice is raised a little. They vibrate, in fact, themselves, synchronously with the iron diaphragm, and nothing is more simple than to calculate the amplitude of the vibrations of the diaphragm from that of their oscillations.

It is certain that the additional weight of 0·45 grams placed upon the diaphragm, must render its movements somewhat less extensive ; hence the results obtained fail rather on the side of deficiency than of excess.

To value the displacement of the rings, we arrange before the telephonic receiver, into which a continuous sound is emitted, a turning disc pierced with slits. It

is found that at a certain speed of rotation the rings reappear distinctly. If we then blow across the disc, making it act a siren, we find that the sound produced is in unison with that transmitted by the telephone. If it lowers or rises slightly, the rings oscillate, at first slowly and then with such a rapidity that they again become invisible. Whilst they oscillate, this displacement may be easily estimated. In an experiment made, the amplitude of the vibrations of the receiving plate was from two to three ten-thousandths of a millimetre.

If we throw into the telephone currents of different intensities, but very small, and none of which produces a displacement of the rings beyond half the distance which separates them, we may, by considering a point of the glass plate infer from its brightness the intensity of the current. This singular galvanometric procedure might, without doubt, be utilised in a telectroscopic receiver.—*Comptes Rendus.*

ON THE CHEMICAL WORK EFFECTED BY THE BATTERY.—By M. D. Tommasi.—An element with a mixture of chromic and sulphuric acids should evolve, according to Favre, 117·3 calories, though only 62·5 calories are transmissible to the circuit. It would then result that a single chromic acid element would not decompose water acidulated with sulphuric acid.

In fact, if the positive electrode of this element is of platinum the water is not decomposed; but if the electrode is of carbon or of platinum sponge, electrolysis takes place. The chemical reaction produced within the element being always the same, I have sought to determine approximately, by means of electrolysis, what is the number of calories transmissible to the circuit by a chromic acid element, according as its positive electrode is of platinum, of carbon, or of platinum sponge.

(*a.*) *Chromic Acid Element with a Platinum Electrode.*—This element does not decompose water acidulated with sulphuric acid if the electrodes of the voltameter are of platinum, but the decomposition takes place if the positive electrode is of silver. A chromic acid element and a Regnault element decompose water with platinum electrodes to the voltameter.

A chromic acid element decomposes the water contained in two voltameters if the two positive electrodes are one of silver and the other of copper. Hence the electromotive force of this element must be intermediate between 62 and 69 calories. The number of calories transmissible to the circuit, as given by Favre, 62·5, thus closely approaches that found in a different manner. It is a singular fact that an element which liberates 117·3 calories should not transmit to the circuit in the form of electric energy more than 70 or at most 72 calories, as otherwise it would decompose water acidulated with sulphuric acid. I will return to this question when speaking of an element with oxygenated water which presents the same anomaly.

(*b.*) *Chromic Acid Element with a Carbon Electrode.*—The water of the voltameter being acidulated with sulphuric acid, there is electrolysis either with both electrodes of platinum, or with a negative electrode of platinum and a positive of copper. This element, if associated with a zinc-platinum element in dilute sulphuric acid, ought to decompose if its electromotive force is really = 117·3 calories. These experiments show that the electromotive force of the chromic acid element with a carbon electrode should not be less than 82, nor greater than 90 calories.

(*c.*) *Chromic Acid Element with an Electrode of Platinum Sponge.*—The chemical work produced by this element is sensibly equal to that produced by the former element, whence its electromotive force should be estimated at about 8 (85 ?) calories.

It results from these experiments that the chromic acid element, as employed by Favre—that is to say, with a positive electrode of platinum—only produces an exterior chemical work of 65 calories.

If we substitute for platinum in the same element carbon or platinum sponge, we may render 85 calories transmissible to the circuit.

If we compare the electromotive forces of chromic acid elements as determined by means of physical procedures, we find, according to the nature of the positive electrode, the following values:

Carbon = 1·574, platinum = 0·977, copper = 0·961, platinum sponge = ?

The decrease of the electromotive force observed in the chromic acid element with a copper electrode is because this metal being attacked by the mixture of chromic and sulphuric acid, even if the circuit is open, occasions a current in the opposite direction to the primary one. As for the electromotive force of the chromic acid element with an electrode of platinum sponge, it has not yet been determined; but we may foresee, according to what has been said, that it will probably be very near to the electromotor force of the chromic acid element with a carbon electrode.—*Comptes Rendus.*

ON THE CHARGE OF DIELECTRICS.—By MM. Villari and Righi.—Villari had observed that on lashing one side of an ebonite plate it was charged, as is generally known, negatively, whilst the other side without contact with a conductor took a positive charge, the opposite of what is generally supposed. Righi, on the other hand, found that the latter charge only appears after the lapse of some time and is therefore secondary. On repeating the experiments together, when the anterior surface was rubbed with cat-skin and then laid upon a plate which had been previously discharged, the lower surface when examined by means of a mixture of red lead and sulphur or of a test-disc was generally found positive. If the experiment is performed rapidly or if the ebonite plate is heated or thoroughly dried over chloride of calcium it appears negative. If exposed for some time to the air it is positive again. The latter charge is therefore secondary.—*Wiedemann's Beiblätter.*

ON THE LUMINOUS AND SPHEROIDAL PHENOMENA WHICH ACCOMPANY THE ELECTROLYSIS OF LIQUIDS.—By M. Slouguinof.—It has long been known that under certain circumstances electrolysis is accompanied by luminous phenomena at the electrodes, but these appearances have till lately remained almost unnoticed. It has been established that light appears at the electrode with which the circuit of a battery of many elements is closed by plunging it into an electrolyte already connected with the other pole of the battery. The author has found that if two equal electrodes are plunged unequally deep into the electrolyte, on closing the circuit of a sufficiently powerful battery a luminous phenomenon appears at the electrode which is less deeply immersed. This electric luminosity may be of two kinds, one of which is a consequence of the spheroidal state which the liquid assumes at one of the electrodes in consequence of the action of the current. Just as metal when raised to a high temperature repels any liquid which is brought in contact with it, so a liquid is repelled by a metal which is being traversed by a powerful galvanic current; in other words, both heat and electricity can throw a liquid into the spheroidal state. Both these agencies may occasionally act conjointly. The electro spheroidal condition is accompanied by a faint luminous appearance. Besides this electrolytic light there is also a luminosity of another kind, and if it takes place at the cathode, particles of platinum are detached from this electrode. In case of the development of light at the cathode and in a solution of platinum chloride in hydrochloric acid, the intensity of the light depends on the heating of the platinum powder which is there separated.—*Carl's Repertorium der Experimental Physik.*

A GALVANIC ELEMENT.—By C. Baudot.—The author modifies a Bunsen element by using, instead of one earthenware cylinder, two, the one placed in the other, both filled with nitric acid. The carbon is placed in the interior vessel.—*Wiedemann's Beiblätter.*

IMPROVEMENTS IN SECONDARY GALVANIC BATTERIES.—Amongst the many practical or unpractical proposals for the construction of secondary batteries, must be included the following:—

The electrodes, formed of spirally-coiled polished plates or wire brushes, *e.g.*, of silver, plunge into a vessel filled only to a little depth with water, but chiefly with oil. The oil is to form a badly conductive coating upon the electrodes, so that the cell may charge itself electrostatically. For the electrodes may be substituted baskets filled with coke, or two strata of coke separated from each other by wadding.—*Wiedemann's Beiblätter.*

NEW PATENTS—1882.

3779. "Electric lamps." B. J. MILLS. (Communicated by W. M. Thomas.) Dated August 9.

3795. "Electric lamps or lighting apparatus." W. R. LAKE. (Communicated by J. B. Wallace.) Dated August 9. *Complete.*

3802. "Secondary batteries." C. T. KINGZETT. Dated August 9.

3803. "Telephonic apparatus." S. P. THOMPSON. Dated August 9.

3812. "Electric secondary or storage batteries." J. S. BEEMAN, W. TAYLOR, and F. KING. Dated August 10.

3813. "New apparatus for regulating and measuring electric currents." J. S. BEEMAN, W. TAYLOR, and F. KING. Dated August 10.

3814. "Electric lamp apparatus." H. J. HADDAN. (Communicated by C. F. Brush.) Dated August 10.

3815. "Improvements in type-writers and in the method of producing symbols by the same; also applicable to printing telegraphs." H. J. HADDAN. (Communicated by B. Schmitz.) Dated August 10.

3820. "Magneto-electrical apparatus for signalling on railways." J. H. JOHNSON. (Communicated by F. and J. Ducousso and the Société Anonyme Maison Breguet.) Dated August 10.

3821. "Electric lamps." F. MORI. Dated August 10.

3822. "Batteries for the storage of electricity." F. MORI. Dated August 10.

3824. "Meter or registering apparatus for the electric light." A. M. CLARK. (Communicated by L. Hours-Humbert and J. de B. de Liman.) Dated August 10.

3825. "Electro-motors." S. H. EMMENS. Dated August 10.

3827. "An improved vessel or station for automatically compressing and storing air by the action of the waves of the sea, and also for the generating of electricity by means of this compressed air." C. W. HARDING. Dated August 10.

3834. "Regulating electric light." H. WILDE. Dated August 11.

3842. "Suspending telegraph wires from iron posts." H. C. JOBSON. Dated August 11.

3846. "Regulating electric currents." W. S. SMITH. Dated August 12.

3856. "Electric lamps or lighting apparatus." W. R. LAKE. (Communicated by N. E. Reynier.) Dated August 12.

3861. "Electric incandescent lamps." G. PFANNKUCHE and A. A. DIXON. Dated August 12.

ABSTRACTS OF PUBLISHED SPECIFICATIONS, 1881.

5668. "Dynamo-electric machines, &c." SIR WILLIAM THOMSON. Dated December 26. 1s. 10d. Consists of improvements in dynamo-electric machines, and which may be employed either for generating electric currents, or for developing mechanical energy from electric currents. One of these improvements consists of a revolving metallic brush, to perform the functions of the fixed metallic brushes or combs which have been hitherto generally used for making the contacts with the commutator bars. By means of this brush the desired effect is produced with but little friction, the mechanical action being chiefly rolling. The requisite rigidity, or quasi-rigidity of the roller is given partly by the elasticity of its constituent metallic parts, and partly by centrifugal force. [This is an important patent.]

1882.

14. "Apparatus for electric lighting." ANDREW MACKIE. Dated January 2. 6d. Relates to an improved incandescent lamp constructed with two or more filaments enclosed in an exhausted glass globe, and to which there is connected a regulating arrangement whereby any surplus currents of electricity over and above that required to make a single filament incandescent is shunted into the next filament or filaments, according to the strength of such excess of current, thus preventing any one of them being overheated and destroyed, and admitting of the illuminating power of every lamp in a circuit being increased by simply increasing the main current to a suitable extent. In carying out this invention the inventor proceeds as follows. All the positive terminals of the filaments in the globe are connected to studs let into a piece of insulating material, the studs being fixed at a certain distance apart; the branch positive conductor from the main lead being attached to the first of the studs. On the first stud there rests a sliding contact piece of such size and shape that when moved to the necessary extent it can cover and make contact with the whole of the studs. This contact piece is attached to a spindle connected to the armature of an electro-magnet, a small spring being arranged so as to press the armature away from the magnet. When a normal current on its way to stud No. 1 passes round the coil of the electro-magnet, this latter overcoming the pressure of the spring attracts the armature and so draws the contact piece into close proximity to the second stud; but should an excess of current occur either accidentally or intentionally, such excess over and above the normal current will draw the armature still closer to the magnet, and so cause the contact piece to slide over and make contact with one or more studs according to the amount of such excess of current, thus throwing the corresponding filaments into action.

29. "Secondary batteries." D. G. FITZGERALD and C. H. W. BIGGS and W. W. BEAUMONT. Dated January 3. 2d. Relates to the improvement of secondary electrical batteries. According to one part of the invention electrodes are obtained having an increased surface or porosity by utilising what is known as local action occurring between lead and a metal electro-negative to lead. The electrodes are obtained by depositing on or in plates of lead or of lead alloy by chemical, electro-chemical, or mechanical means, a metal electro-negative to lead, such metal being in most cases subsequently removed preferably by making the plate an anode in a solution which does not form a soluble salt of lead. (*Provisional only.*)

49. "Measuring and recording quantity of electricity," &c. JOHN HOPKINSON. Dated January 4. 6d. Relates to the methods of measuring the whole quantity of electricity which passes through a conductor. For this purpose the inventor makes use of a centrifugal governor or centrifugal apparatus and controls its velocity by electrical or electro-magnetic apparatus. The centrifugal force of the governor may be opposed by the attraction or repulsion of one conductor conveying electricity on another conductor conveying electricity, of an electro-magnet for its armature or of a solenoid for its core. Or the centrifugal force may move one contact piece or its equivalent and the electrical apparatus a second contact piece in such wise that as the speed of the governor increases the former piece or its equivalent is moved from the second whilst as the electrical force increases the second piece follows up the first. When the centrifugal force is mechanically opposed to the electrical force the governor may act by bringing a friction brake into action or it may act by making and breaking an electrical contact. The governor may be driven by a small dynamo-electric machine or in the case of using a brake the governor may be driven by clockwork.

55. "Apparatus used in the distribution of electrical energy." JOHN PERRY. Dated January 5. 4d. In the distribution of electrical energy from a central source it is very important that any person to whose premises conducting wires are laid should get a supply which is quite independent of the demand from and supply to other consumers of power. The inventor's method is to use one or more magneto-electrical machines or some other form of electrical machine or battery which will produce in a circuit an electromotive force which is constant and independent of any other electromotive forces in the same circuit, and in addition to this to have in the same circuit one or more dynamo-electric machines.

64. "Magneto and dynamo-electric machines." LORENTZ ALBERT GROTH. (A communication from abroad by R. J. Gülcher, of Austria.) Dated January 5. 6d. Has for object the reduction or obviation of the injurious heating of the wire coils, and thereby the production of an increased useful effect in the machine. According to these improvements the inductor rotating between the magnetic pole surfaces consists of a ring, the core of which is formed of separate magnetically insulated strips (Lamellen) of soft iron in order to facilitate the change of the magnetic poles during the rotation of the ring, and thus to reduce the heating of the ring itself to a minimum. The section of the ring differs materially from those of other machines, being either of a wedge shape, that is, triangular, or of a wedge-shaped pointed square or rectangle. This form not only permits of a convenient and solid fixing of the inductor, but also allows the wire bobbins wound round such a ring to be exposed to the inducing action of the magnetic pole surfaces from all sides, and thereby completely obviates the production of heat, which in other machines is formed in the passage of the electric current through the unexcited wire parts. The magnetic pole surfaces are formed in all their parts of a U-shaped section, and enclose the rotating ring in such manner that the legs of its cross section project out on both sides over the wedge-shaped points of the section of the ring, and the latter is thus exposed on all sides to their inducing action.

69. "Manufacture of incandescent lamps." E. H. T. LIVEING and C. V. BOYS. Dated January 6. 4d. Relates to modes of manufacturing incandescent lamps, whereby their expense is reduced or their conducting threads more easily replaced when damaged or destroyed. In the first class of lamp, where cheapness is obtained, the inventors avoid the use of the platinum wires sealed in the glass which have hitherto been employed in vacuous lamps to make electrical connection with the carbon thread and the wires outside, and use instead a pair of conducting wires, suitably insulated, passing through a narrow tube or tubes sealed on to the globe, and they prevent the entrance of air into the globe through the tube by partly filling it with well-boiled pitch, or other resinous or suitable cement, which will not give off sufficient vapour to injure the lamp.

71. "Automatic electric-printing registers, &c." A. J. BOULT. (A communication from abroad by B. E. Valentine, of New York, America.) Dated January 6. 10d. Consists of automatically receiving and forming a permanent register of electric signals. It consists of one or more transmitters, or signal boxes, for sending signals by the breaking of a circuit. The chief features of the signal-box being a revolving wheel, having on its first quarter the notches to denote the nature of the signal. On the next quarter and on the third quarter notches to denote the number of the station whence the signal is sent, and on the last quarter an independent contact surface to switch a main circuit through a bell magnet to enable a return signal to be sounded at the transmitter.

72. "Secondary or reversible electric batteries." RANKIN KENNEDY. Dated January 6. 2d. Has for its object to improve the construction and action of secondary or reversible electric batteries. A battery made according to the invention consists of one or more vessels, each of any convenient shape, made of wood or other suitable non-conducting material, and capable of holding a quantity of dilute sulphuric or other suitable acid. Immersed in the dilute acid there are plates of lead, tin, iron, or other suitable metal, or of conductiug carbon, prepared in such manner as on being charged by an electric current from

a dynamo-electric machine or other source to become the receptacles of oxygen and hydrogen due to the decomposing action of the current, the oxygen being absorbed in, or in connection with, one kind of plate, and the hydrogen in, or in connection with, another kind of plate. After being charged in this way the battery is capable of being used to supply an electric current. (*Provisional only.*)

95. "Electric lamps." W. J. Mackenzie. Dated January 7. 6d. Relates to improvements in, or connected with, electric arc lamps, which consist (firstly) in special means whereby the feeding of the carbon pencils or electrodes is controlled, and their resistance minimised; and (secondly) in novel arrangements of regulating appliances connected with electric arc lamps, to be used either in combination with, or separately from the first part of the improvements, whereby more perfect regulation of the distance between the electrodes may be secured for the purpose of maintaining the arc steadily.

118. "Telegraphy." Peter Jensen. (A communication from abroad by F. W. Jones, of America.) Dated January 9. 4d. Relates especially to duplex cable telegraphs, and the object is to provide an efficient means for overcoming the disturbing effects of the electrical discharge from the cable upon the receiving instrument at the home or sending station. (*Provisional only.*)

120. "Storing Electrical Energy, &c." J. E. Liardet. Dated January 9. 8d. Has for its object improvements in the means of and in the apparatus for storing electrical energy and in the preparation of the materials to be employed.

129. "Electrically lighting railway trains." W. H. Preece. Dated January 10. 6d. Relates to the lighting of railway carriages by electricity, the object in view being to provide means of generating a practically uniform current of electricity notwithstanding the stoppage of the train or variations in its speed. For this purpose from one or more of the running axles of the train the inventors work air-compressing pumps, so as to charge one or more reservoirs with compressed air. This compressed air is employed to work an engine or engines which work suitable dynamo-electric machines, the air engines having their supply regulated so as to maintain as nearly as possible uniform speed.

144. "Secondary galvanic batteries." H. J. Haddan. (A communication from abroad by Dr. Emil Boettcher, of Leipzig.) Dated January 11. 2d. Relates to secondary galvanic batteries or accumulators, and consists in the application of zinc vitriol as exciting liquid, and of zinc and oxide of lead as electrodes, the action of these elements being as follows:—An electric current from a dynamo-machine passing through a solution of pure sulphate of zinc (one part of the salt to three parts of water) decomposes the said salt, and causes a deposit of zinc on a thin plate of pure zinc, the diluted sulphuric acid (1 to 10) being not strong enough to attack pure zinc. The other pole is formed by thin lead foil, folded several times, in order to augment the active surface, and covered with a thick layer of pure litharge. The oxygen, coming in contact with the said lead foil, produces a very thin layer of peroxide of lead. By closing the galvanic element thus formed, the zinc previously deposited is again dissolved, and thereby the sulphate of zinc produced, while the hydrogen reduces not only the peroxide formed on the lead plate, but also a layer of the oxide of lead, thereby forming metallic lead. If now the current from the dynamo-machine is again passed through the element, a new deposit of zinc is formed on the zinc plate, while on the opposite pole not only the previously reduced peroxide of lead, but also the lead formed from the oxide, is again oxidised into peroxide of lead. By a few repetitions of this process, the secondary galvanic element is completed, and has acquired high electromotive power.

185. "Electric accumulators." H. J. Haddan. (A communication from abroad by Augustin Morel, of Roubaix, France.) Dated January 13. 2d. Has for its object to reduce the weight of electric accumulators, and consists in the application of a series of receptacles provided with two metallic blades or other good conductors which serve as poles for the decomposition of water or other suitable liquid. If an electric current is made to pass through these elements, the receptacles are filed with gas, water yielding one volume of oxygen and two volumes of hydrogen. If now the current is broken or diminished, the oxygen combines again with the hydrogen to form water, thereby yielding the exact amount of electricity which has been previously spent. (*Provisional only.*)

197. "Apparatus for the transmission and reception of sounds." W. C. Barney. Dated January 13. 2d. In order to protect as much as possible a microphone or current regulator from the evil necessarily attendant upon the use of a thin vibratory plate in connection therewith, the inventor places the microphones inside a box made of wood, cork, ebonite, felt, or any equivalent material, the material surrounding the microphone being of sufficient thickness to reduce to a minimum any vibratory movements which the sound waves may give to the material, thus leaving the microphone to be acted upon by the molecular movement of the material to which it is attached. This box is not fixed to any substance, but merely rests on the top of a box containing the induction coil, where it is retained by its *vis-inertiâ*. (*Provisional only.*)

319. "Construction of secondary batteries." J. S. Sellon. Dated January 21. 2d. Relates to the construction of the terminal plates, supports, retainers, or frames upon or in which the active material or agent is deposited, placed, or fixed in the construction of secondary batteries, the object of the said invention being to render the plates, supports, retainers, or frames more durable than as they are ordinarily constructed. In carrying out the invention the [illegible] constructs such plates, supports, retainers, or frames partially [illegible] pieces or rods of any convenient shape or combination of [illegible]tly of, metal, carbon, or of other suitable material [illegible]nductive in itself or can be rendered conductive, on or to which are attached, connected, or affixed, strips or pieces of lead or other suitable metal or material, such strips or pieces being of any convenient form for retaining on the surfaces or in the cavities, interstices, cells, or spaces the active material in a divided, finely divided, pasty, deposited, or other convenient, or desirable condition.

224. "Electric-lighting apparatus, &c." W. R. Lake. (A communication from abroad by J. S. Williams, of America.) Dated January 16. 6d. Relates to the manufacture or construction of electric lamps, candles, or lighting apparatus which will be more durable and efficient than those hitherto provided, and the said invention consists in various improvements as specified.

1437. "Electric accumulator." Sigismund Cohné. Dated March 25. 4d. Relates to a new or improved accumulator for the storage of electric energy (commonly called storage of electricity) for the purposes of electric lighting and electromotive power, whereby the inventor obtains a larger capacity of storage combined with greater efficiency and durability. Hitherto the cells of the accumulators in use are liable to polarise themselves and require a considerable volume and weight, or the electrodes are quickly destroyed. The object, therefore, of the invention is to obviate those defects, and also to simplify the construction of the accumulator whereby it is more readily applicable to different uses.

According to the invention, the inventor applies on the surface of a sheet of lead of any convenient size (by preference about a foot square and about 1-16th of an inch thick), a layer of mercuric sulphide, HgS, say, about six ounces to the square foot, whether amorphous or crystallised, by preference the crystallised HgS, called cinnabar or vermillion is used, and bends the coated sheet into the form of a box or into the form of a spiral, so that the layer cannot be removed by the acid. This prepared sheet is used for the positive electrode. A second sheet of lead rather less in size is arranged and prepared in the same way as the first one, for the negative electrode. Both sheets are perforated and placed so as to be separate or apart from each other into a jar or box filled with diluted sulphuric acid in the usual way, and then charged by the ordinary known process.

DISCLAIMERS.

The Edison Electric Light Company (Limited), "Electric lamps." No. 578. 1880. "Magneto-electric machines." No. 3964. 1880. "Connecting the carbon ends to conducting wires on electric lamps." No. 768. 1881.

CITY NOTES.

Old Broad Street.

THE METROPOLITAN (BRUSH) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

On the afternoon of Friday, the 11th inst., at the City Terminus Hotel, Cannon Street, under the presidency of Sir Michael Kennedy, R.E., K.C.S.I., an extraordinary general meeting of the members of this company was held.

The secretary, Mr. Robert Wilson, having read the notice convening the meeting

The Chairman said: This is a special meeting held merely for the purpose of confirming a resolution passed at the former special meeting. As soon as we have confirmed the resolution we shall be in a position to obtain from the Committee of the Stock Exchange a quotation. We have already, as you are aware, had a settlement. I therefore simply beg to move the following special resolutions, modifying the articles of association, duly passed at the extraordinary general meeting of the company held on the 24th July last be and the same are hereby confirmed:—

1. That the following words be inserted at the end of Article 4: "Provided always that no share shall be issued at a discount without the sanction of a general meeting."
2. That in lieu of "1886," occurring in Articles 81 and 89 respectively, "1884" be inserted.
3. That Articles 85 and 100 be and they are hereby expunged.

This was seconded by Mr. James Whitehead (vice-chairman), and carried unanimously.

Statutory Meeting.

The Secretary then read the notice convening the first ordinary general statutory meeting, which accordingly took place.

The Chairman said: Gentlemen, this is our first general statutory meeting, and, as is usual on such occasions, we have not much to communicate to you. Up to the present time our business has been chiefly the organisation and preparation for the work which is doubtless before us, and which we hope to carry on on a very extensive scale when the winter brings us long dark nights and often dark days. The company was incorporated on May 15th with a capital of £1,000,000 sterling, in 200,000 shares, of which 100,000 shares were first offered. 392,686 shares, or very nearly four times the number offered, were applied for, and the whole number available—100,000—were in the first instance allotted. This number was reduced by 310 withdrawals, which, after full and careful consideration, the directors were constrained to admit upon legal grounds. We engaged suitable, but not extravagant, offices at 110, Cannon Street. One of your first directors, Major Wood, resigned his seat at the board, finding that very onerous calls upon his time in other directions rendered him unable to give that attention to our affairs which their importance necessitated. But the board was strengthened by the accession of Mr. Rose, of the firm of Morton, Rose, and Co., a gentleman well known to you all by reputation at least. We entered into a working arrangement with the Hammond Company, under which we secured the services of Mr. Hammond as our managing director on terms based upon a share of the profits. Mr. Hammond had before gathered together a considerable staff, and had explored,

so to speak, the requirements of the metropolis as regards electric lighting. He had also established a lighting station at Westminster and another in Holborn. Mr. Hammond's reputation as an energetic man of business and a successful organiser of the Brush system must be very well known to you all. We felt that in making this temporary arrangement we did the best in our power to provide for a successful starting of our operations. We appointed Mr. Wilson, a gentleman who has had great experience in public companies, to be our secretary. As soon as our organisation had been completed, we proceded to lay the foundation of the extensive business which we trust is before us. We advertised in all the newspapers; we gave a wide circulation to the pamphlet prepared by our managing director, giving prices of plant and machinery, estimated cost of installations, &c. Up to the present time our work has been confined mainly to small private installations. As regards public lighting, although we have been in communication with many authorities, we have found that on their part they have an objection to make any movement till the Electric Lighting Bill has become law. All those gentlemen who are concerned in electric lighting must have followed the course of the bill with a considerable amount of interest, though perhaps also with a little apprehension. I was prepared to address you in somewhat different terms to those I shall now have to adopt, for I am happy to inform you that in Committee of the House of Lords on Tuesday the bill underwent considerable and material modification. The terms for which licences can be granted with the assent of the local bodies was altered from five to seven years, and the period for which provisional orders can be granted from fifteen to twenty-one years. This is no doubt a considerable concession. But the objectionable clause of the bill is a compulsory sale clause which still remains in it in the inequitable terms, if I may so express myself, in which it was first drafted; and it is to this point we shall have to direct our future efforts. Under this clause, as you are well aware, electric light undertakers are liable to be compelled to sell their plant and property at the end of the period for which a provisional order has been granted for the mere price of the materials, without taking into consideration anything regarding the goodwill of the concern. This I consider very bad. But it might have been justified to some extent had there not been in the bill a clause which regulates the price at which electricity shall be supplied to consumers. The existence of this clause restrains electric undertakers from making large profits, while the sale clause compels them to sell their property at a time when in all probability they had begun to reap the fruits of their enterprise. As regards our action under the bill we have matured the steps that we shall adopt and which we intend to take as soon as possible. It would not be advisable for me to make any detailed statement of what those steps are. All that I can tell you is that we have arranged what shall be done, and to lose no time in doing it. It is very encouraging, gentlemen, to find that there is a general and growing opinion that the electric light enterprise has before it a great and immediate future. Wherever the subject is discussed, whether it be in Parliament or out of Parliament, or in the columns of the public press, the sentiment is almost universally expressed. In an article in the *Times*, of the 17th July—I don't know whether you have all seen it—there are words to the effect that, "there is a vast field of electric work, and so far from having to educate the public to the use of electricity, as some seem to contemplate, those who are concerned in its distribution will soon be applied to by more customers than they can deal with." This, gentlemen, has up to the present time been our own experience. We have joined also in a very important movement. You are aware that there are many companies who derive their licences, as we do, from the Anglo-American Brush Corporation. We have thought it advisable to join a conference of those companies, their boards having agreed to send delegates to form a council. Our licences are similar but our districts entirely distinct. We have a common cause and no conflicting interests. We therefore thought that for united action and protection of common interests, a council of that description would have a very important effect in protecting the Brush interests. Already the council has met and arranged its procedure, passed important resolutions as regards the quality and price of plant and material, which it receives from the Anglo-American Brush Corporation. These, gentlemen, are all the remarks I have to make, and if any gentleman has any questions to ask I shall be glad to answer them to the best of my ability.

Mr. Campbell asked whether the 310 which were withdrawn were subscribers or shares?

The Chairman replied that they were shares, not subscribers.

A shareholder asked if the company were doing any business at the present time?

The Chairman said they were doing business in many directions.

The shareholder, continuing, said they held meetings occasionally, but he thought they heard nothing definite.

The Chairman answered that they were preparing to do business when business arose. They were doing business to a very considerable extent, and he might mention from memory, Covent Garden.

Another shareholder: You are earning money at the present time?

The Chairman: Yes, sir.

Mr. Price said he thought many of the shareholders were dissatisfied, and he should like to ask a question or two. The Camberwell Streets Committee asked for tenders to light with electricity the streets in their district. Only one tender was sent in. Was it theirs? And if not, why did they not tender? Did they possess the right to manufacture their own carbons, or were they manufactured in New York and sent over here? As there seemed to be a doubt as to whether electric lighting could compete with gas in regard to price, he should like to ask whether the last tender would be remunerative for lighting certain districts in the City? Were the lighting of certain railway stations in the metropolis remunerative contracts? He should be very pleased with a plain answer.

The Chairman thought that all those questions could be very easily answered. As his friend, Mr. Hammond, was more acquainted with the practical details of those matters, he would ask him to reply.

Mr. Hammond said, as the gentleman before the previous speaker had asked a question which involved a great principle in the business of the company, he might be pardoned if he dealt with it as well as the chairman. An electric lighting company, in its initial stage, had a great deal of ground to cover in the way of preparing for business, and if they got no fruits from them they would certainly be in a great mess. One was also anxious not to be too closely questioned as to the mode of organisation they had pursued in the metropolis, though he should like to make them as enthusiastic as he was himself as to what was being done in a quiet manner to cover the whole place. If he were to take them into the office and show them the streets all named, the traveller of each put to them, and the days upon which they visited these districts, they would form some idea of how the districts were being covered. They did not want to tell their friends outside all they were doing; but he could assure them there was no spot in the metropolis that was not being covered by this company. That preliminary work was being carried out with as little expense as possible, and they felt that where £1 was spent in this manner they would get back £3 in its place. Their time up to the present had by no means been lost. In the matter of grouping together districts, and the hiring out of lights, it was their policy to get the customers first and then put down central stations in the midst of them. He felt that amongst friends he must ask their forebearance, because he could not say too much. He could not, however, sit there and hear a hint that they were spending money to no purpose. That was not so. With regard to the Electric Lighting Bill, he might say they did not like it. However, they were glad to see that the Lords amended the compulsory purchase clause from fifteen to twenty-one years. For his own part he was now satisfied with the bill as a preliminary piece of legislation in this line, and he hoped that by next year it would be considerably improved in their favour. Personally he felt that the bill should go on, rather than that they should block it. There was a certain work connected with the bill which would prove of immense value to this company. They were conscious of that, and he said no more. The one tender sent in to the Camberwell vestry was that sent by this company. That tender, if it had been accepted, would have formed the basis of the systematic lighting of Camberwell, which would have left a considerable profit to this company. He would be the last man in the room to dodge the question asked, but he must say that if they were to have to put down gas mains merely to light a certain place, and were not allowed to light places *en route*, it would be done at a great loss. Gas companies put down a main, and said to themselves "we shall have the lighting *en route*," and they put the price down; otherwise the price per 1,000 feet would be 21s., or five times the ordinary charge. What was asked for with regard to the gas question, they asked for the electric light. They said: "get this light and you will get that." They based their price upon what would be remunerative when the whole thing was a going concern and in fair working order. If they did not adopt that principle, they would ask such prices that the vesteries would not listen to them. He was careful to put in that tender that the company would only do the lighting on condition of having the lighting *en route*, and after one year. They would not give the company the lighting *en route* after one year. Everything with regard to that tender was considered from the point of view of the interests of the company. With regard to carbons, he was glad to tell them that the company had every power to get their carbons in the cheapest market, but they were bound to the Brush Company for their machine and lamp; although, as a matter-of-fact, they found it convenient, considering the organisation the Brush works had, and the apparatus they had, to go to them for materials; yet in carbons they were perfectly free. As a matter-of-fact, at the moment, they went to the Anglo-American for their carbons; this company had an arrangement with them whereby they could buy on cheaper terms than they could get them from anybody else. He believed it was true that the Anglo-American Company got their carbons from America, in doing so they got them under very special terms with the patentees there, who had the right to make them in that particular manner. He could assure the shareholders that the directors kept a serious eye upon that question. The man who got the lighting generally got the order for the trimmings required afterwards. If they were to light the hotel in which they were assembled, which was quite within the bounds of possibility, they would probably get all orders for trimmings, carbons, &c., afterwards. He could dispose of the third question by saying that this company did not tender for lighting in the City, but that would only be a technical way of meeting the question. The City tenders were closed the day before this company had its capital subscribed, and it was therefore impossible for the company to tender. A tender was put in on behalf of the Hammond Company, and an arrangement was made between that company and this that they should have a mutual benefit. He had really answered the question as to the remunerative part of this undertaking in his answer concerning Camberwell. The undertaking would have left a profit if they could do the lighting by their mains *en route*. With regard to certain other lighting in the City, with one exception, the railway companies, after a trial of the plant, have paid for it, so that no question of yearly profit arose, except the profit which arose from supplying carbons. The Great Eastern Railway Company tried the light, and finding it worked satisfactorily, gave a cheque for the amount. The only station which was not in that position was Charing Cross, and in that case the parent Brush Company was running that station for the cost of the gas bill, in order, primarily, thoroughly to show what its system could do. They were running it under such favourable circumstances that they felt themselves recouped by the gas bill; for instead of having to put up a separate installation they were running it from their works at

Lambeth, a thing which was only possible with the Brush system. When they went to Lambeth and saw the whole lighting done from one machine, through five miles of wire, and when they went to look at an opponent's system, which required for the same amount of lighting thirteen dynamo machines and eighteen wires, then they saw that the Brush was ahead at the moment of every other system, and would, they hoped, remain so. The position at Charing Cross was simply turning the power, which otherwise would drive a lathe, on to a dynamo machine.

In reply to a question, Mr. Hammond said that the lighting of Charing Cross and the City was the only piece of Brush lighting not done by the Metropolitan Company.

The Chairman, in answer to a question as to the concession received by this company from the Hammond Company, stated that the Hammond Company had received a concession for the City of Westminster, and they had also a lighting station at Holborn; and it was in order to extinguish these rights that an arrangement was entered into with the Hammond Company.

Dr. Rosenthal said he should like to ask what was the position of the company with regard to satisfying the want of an independent secondary battery, or accumulator; for he felt that in future an accumulator would be quite as important an element in their work as the dynamo machine.

The Chairman replied that the consideration of an independent accumulator was engaging the very earnest consideration of the board. There were the Faure, Sellon-Volckmar, and other accumulators in the field, but the policy of the directors with regard to this matter had been one of waiting, because they were not quite satisfied with the efficiency of those accumulators. They had very good hopes and expectations that the results which had hitherto been obtained from the accumulators now considered the best, would be excelled by others; and they had therefore felt disinclined to pledge their capital in that which was good now, but which was likely to be superseded by something better.

Mr. Bigg said he should like to ask a question or two. He had understood that 390,000 shares had been applied for, and 100,000 were allotted, and 310 were withdrawn. Was the £3 paid upon the remaining 100,000? Did the directors of this company themselves take a large interest in the undertaking?—for that would inspire the shareholders with a great deal of confidence—or did they simply take their qualification? What prospect was there of their making a further call? He found that their shares could be obtained at 1¼ discount, and he thought any further call would be ruinous to their finances.

Mr. James Whitehead replied, with the chairman's permission. He said that out of the total sum called up, of £300,000, there only remained £3,645 unpaid. And while he was on his feet, he should like to reply perhaps more fully, if Mr. Hammond would excuse him, to the question put by a gentleman in the body of the meeting, with reference to the price of electricity, as compared with gas, in the City. He did not know whether all those who had considered the question had fully taken into account the very large extra amount of light given to the public by the electric system. For the sake of argument, they would compare themselves with the gas burners, according to the improved system, with an extra consumption of gas, and the effect of that would show that in the four districts for which this company tendered through the Hammond Company, in the City, the cost of gas would be £7,250, which was more than double their tender for electric lighting—for their tender was for £3,725, allowing £725 for wear and tear. With reference to the Electric Bill, they had felt that the compulsory sale clause was not only unfair to this company but to all electric lighting companies. He did not want to depreciate the value of their property, but he thought if they could get the present bill altered so that they could get a fair chance against gas, then they would be able to make this company a successful undertaking, not only so far as electric lighting of the metropolis was concerned, but also financially. He wanted the shareholders to realise what were the difficulties under which they laboured with reference to the compulsory sale clause as it stood at present. They paid £235,000 for the exclusive right to use the Brush and Lane-Fox patents in the metropolitan area. If, for the sake of argument, they spent another £265,000 in plant, making the £500,000 of issued capital, and if at the expiration of twenty-one years their property was to be taken for the simple value of the machinery, they would see that the £500,000 must be provided for before the expiration of the time when it might be taken over by the local authorities. That was a very serious business. If they said for the sake of argument—of course all this in the present state of things was highly hypothetical—after the expenditure of £265,000 in plant, they had to provide for a total of £473,500 to liquidate the amount expended before the expiration of the twenty-one years, during which they had exclusive right of using these patents in the metropolitan area, and if they assumed that during the twenty-one years they had fifteen years of good work, and divided that sum by fifteen, they would find that they had £31,566 to provide for yearly, besides the usual amount for repairs and wear and tear. He wanted to show them the necessity of putting their shoulders to the wheel in order that they might obtain fair, and equitable and just, rights to enable them to compete against the gas companies already in the field. He thought this was a question which concerned not only the shareholders of that company, but concerned seriously the interest of the general public throughout the entire kingdom. Very few of them would contest the point for one moment that the electric light was not superior in every respect to gas; it was not only more brilliant but it did not affect colours by night; it gave exactly the same light at night for the judging of colours, and in consequence was of great benefit to trades in the kingdom, especially in drapery; but it was also a more healthy and wholesome light, and did not injure their pictures or curtains.

In reply to a further question from Mr. Bigg,

The Chairman said he was not in a position to state what was the interest of the directors in the company. The register was open to the inspection of any gentleman who chose to look at it. He believed the directors had a substantial stake and interest in the concern. As regarded the question in reference to a call, he might say there was no intention to make a call, and no call would be made until the progress of the business was sufficiently advanced to justify it. He hoped, however, they would have occasion to make a call speedily, but they would not do so until they had a good use for the money.

Mr. Hammond said, that in order that his previous remarks might not be misapprehended, or that he might not be thought to differ from his colleagues, he should like to add that he was only satisfied with the Electric Lighting Bill as an instalment of legislation in this matter. He should like to read one clause from which he took a grain of comfort; and he hoped that grain would extend to a tree, under whose branches they might eventually rest contented:—"Thereupon such undertakers shall sell to them their undertaking, or so much of the same as is within such jurisdiction, upon terms of paying the then value of all lands, buildings, works, materials, and plant of such undertakers." "The fair market value" was mentioned. They were not to have quite "old iron price," as one noble lord put it, for there was to be taken into account in the sale a great deal of work, of labour involved in laying down mains, &c., which was so much an element that it should be included in the fair market value of the concern. He was quite willing to note the words which had been pointed out to him: "Without any addition of compulsory purchase, or of good-will, or of any profits which may or might have been or made from the undertaking." He did not think that the two conflicted, but it was well that the shareholders should know that there were two views in Parliament in regard to the bill. He was anxious that all doubts in the matter should be removed by next year.

Dr. Pocock asked whether this company would exhibit at the approaching gas and electric exhibition at the Crystal Palace. It seemed to him that the public mind wanted a great deal of education in the matter of electricity, and he should quite approve of their making experiments to show that they had something good to offer.

The Chairman, in reply, said he thought that if any steps were taken to exhibit, the proper persons to do so would be the parent Brush company—the Anglo-American Company. He was glad to find that the shareholders were with the board in the matter of experiments.

A vote of thanks to the chairman, proposed by Mr. T. R. Denny, and seconded by Dr. Rosenthal, closed the proceedings.

BRUSH ELECTRIC LIGHT AND POWER COMPANY OF SCOTLAND (LIMITED).

The first general meeting of the above-named company took place at Cannon Street Hotel, on Wednesday afternoon. In the unavoidable absence of Lord Crawford, Chairman, the Hon. Ashley Ponsonby, Vice-Chairman, presided.

Mr. F. M. Brockelbank, Secretary, having read the notice convening the meeting,

The Chairman said: Gentlemen, I have not very much to say. We meet to-day for the statutory meeting in conformity with the regulations of Parliament. I am very glad we have had the opportunity of meeting, because there may be many questions asked which we shall be happy to answer to the best of our ability. I may tell you that the Brush Electric Light Company of Scotland was incorporated on the 25th April, and the issue was made to the public on the 27th April this year. The capital was £300,000 in 60,000 shares of £5 each, of which the first issue was £150,000. 8,000 shares were reserved in part payment for the concession by the vendors, and the remainder was offered to the public. We never had, I suppose, in such a company so large a subscription. You will see, then, when I tell you that we had 22,000 shares to offer to the public. We had subscriptions for these representing 373,553, so that you can see the difficulty of allotment. I believe there was some little feeling of irritation that we did not allot quite satisfactorily, but I assure you we did not know what to do in view of the enormous number of applications. We had 2,677 shareholders, which is rather large in so small a company. Now, gentlemen, you may congratulate yourselves on another fact, that you have your settlement and your quotation on the Stock Exchange. I believe many other of the companies who came out have only one or neither of these, which will show you that in our case everything was done to the approval of the Stock Exchange committee, everything was above board, and satisfactory—a matter very pleasing to the shareholders. The secretary reminds me that I have said we have now 2,000 shareholders on the list, there were 2,677 applicants, and now we have 400 or 500 shareholders. I made a mistake by taking the number of applicants as shareholders. We have no intention of issuing additional capital at present, but of course that question will depend on the work we get in Scotland. We are getting applications for tenders for our work daily, and I hope very shortly to be able to show you a very good report of what work is doing and is to be done. You must remember we have been delayed very much in our action by the law proceedings in Scotland, with regard to the liquidation of the old company that is now perfectly finished, so our solicitor tells me. We could not undertake the election of officers or the beginning of work, or of tenders of any sort or kind until we were perfectly sure that we had everything in shape. As you will see in the book now in your hands, we have appointed as our chief electrician and manager in Scotland Mr. Beckingsale, of whom we have the highest testimonials; and we have appointed also Mr. Brockelbank as our secretary; and Mr. Wylie our agent in Edinburgh; and we have another gentleman, Mr. Martin, in Dundee. These are most energetic and urgent in pushing forward the business, and the board of directors are perfectly satisfied with the working of the company in Scotland. Scotland, you may remember, has an advantage over many other places from its abounding in water power. Water

power exists in nearly all large private houses and factories, and this is of immense importance, because when you have the water power you reduce the cost of the electric light to a minimum; whereas, if you have steam power only, you have to add an expense which does not always contrast favourably with gas lighting. Therefore I always look on Scotland as best adapted for the electric light; hence the good field we have. I shall be very happy to answer any questions, as it is not my intention to delay you long.

Mr. J. Walker: Have you done any work in Glasgow, Edinburgh, or Dundee?

The Chairman: We have at the Waverley Station, Edinburgh.

Mr. Walker: It is some time since the company was started. I thought you would have pushed forward more quickly than you have done. Will you explain what is meant by liquidating the old company? It is the first time I have heard of any old company.

The Chairman: We are lighting the Waverley Station, that is, the central station in Edinburgh. We have tenders out for the lighting of the Tay Bridge Station and others for the East Station in Dundee. We have now mills sending up for tenders, and hope shortly to be able to do business in that direction. The Scotch people are very careful; they don't like to jump in the dark. They like the light before they jump.

Mr. Walker: Is it a profitable contract you have, do you think?

The Chairman: We believe it to be so. The Chairman then read from the prospectus the contracts that had been made with the Scottish Brush Electric Light Company, the company who sold their rights to the present company.

Mr. Walker: Has there been any difficulty between the two companies?

The Chairman: Not between us. I do not intend to enter into other people's business. There was a disagreement between that company and the Anglo-American, who are partial vendors to us. They disputed the appointment of a liquidator, and occasioned application to the courts of law, causing considerable delay to us; but there is no hostile feeling with us.

Mr. Walker: Has it entailed any cost to this company?

The Chairman: The solicitor will tell you. I believe nothing at all. They only sold to us, as vendors.

Mr. Walker: I think this should have been mentioned in the prospectus.

The Chairman: I have just read the prospectus.

Mr. Walker: Oh, I had not seen it. Is the price stated?

The Chairman: Yes, in the agreement. It was £15,000 cash and £40,000 fully paid-up shares. It is the similarity of names that has caused a great deal of confusion. People have been wanting to know if we were winding-up, and all sorts of things.

Another Shareholder: I believe the answer just received from you, Mr. Chairman, with regard to the working, is not altogether satisfactory. You started in May. You have done nothing yet beyond the lighting up of stations. You say you are going to do a great deal, but why is not more done? Then, I must say, we have received a very fair statement, but we expected more to be done. The liquidation of the old company ought not to interfere with the progress of our business. The difficulty was simply with regard to the transfer of money received by them from us. I am sorry to see we gave £55,000 for our patents; this amount, if you consider the merits of the system, is an excessive price. You stated in your prospectus that the object of the company was for the purpose of lighting up public streets, public buildings, and private houses. Now, sir, so far as I understand, you are not in a position to light up private houses, that is, you are not able to compete with gas, for the simple reason that you do not possess all that is necessary to compete with other systems, your system being, of course, incomplete. I refer more especially to a very important thing, that is a secondary battery or accumulator. Is that included in the Brush system? I do not believe it is, and without it you cannot complete the lighting of private houses. It is a matter of impossibility, if I can rely upon the opinion of those who ought to know. The speaker said he had been alluding to a speech of Lord Crawford at a recent meeting of the Oriental Storage Company (cries of "Question"). When you said the object of this company was to light up streets and private houses, of course I understood by your system you would be able to do it. Now, such a statement is misleading, and you mislead me for one to subscribe to the company. I would not have subscribed had I known the system was incomplete; and I believe this is the explanation of the shares being at a discount. Then I believe that the majority of the directors of electric light companies are too fond of blaming the purchase-clause of the new Act. Now, sir, I do not believe but that that clause will be amended at some future time; but, of course, it is better—(cries of "Question")—than to be without a Bill at all. Yet I would like to know are all the shares allotted? Have the directors a substantial interest in this company beyond that required to qualify for director (hear, hear).

Mr. Dickson rose, at the request of the chairman, to answer the last speakers. He said: From the time the company was incorporated and the shares allotted, we had of course to face the difficulty mentioned through the liquidation of the old company; and although it has been said that we ought to have gone and plunged into work rapidly, I think that as prudent men we were justified in waiting a little until we saw how those disputes between the Scottish and Anglo-American Brush Company were settled. We had nothing to do but to look out for the shareholders' money, and we would not part with it until the lawyer satisfied us. It would never have done to plunge into work finding we had a lot of lawyers tied to our necks; it would not have been satisfactory at all. With regard to the second question asked, it was known that we were taking over the concession of the other company in Scotland, who had been working before us. We had to see our shareholders well protected. The gentleman who spoke second said we had paid a large sum for concessions—£55,000. But we have not paid that. And I take it that if you will add all the concessions made, the negotiations prove our company not to have got the worst bargains ever obtained. For £15,000 cash we got clear of preliminary expenses, such as advertisements, lawyer's charges, and brokerage. In that direction a great deal of money often is spent. The rest of the £55,000 was paid in shares, and the bulk of the shareholders' money is therefore still in the bank intact. In the third place, as to our going into work. Now, we all know that in the height of summer it is not the time when people rush into light; it is when the dark nights come in that people become sensible that they would like something better than gas. Across the border people are very careful in these matters. When we floated our company, the Crystal Palace show and exhibition was being held. People naturally said, "We will not go in for this till we see which is the best." At the Crystal Palace we were asked to show the Brush system, and I believe Scotch people went away satisfied that that system was the best. But we did not push the business until we saw our way a little clearer. Waverley Station, the lighting of which we have undertaken, is one of the most important in the country. If we do that thoroughly, all the tourists that go south and go north will see it, and we shall thus get a good advertisement. To show you, too, that the North British Company are quite aware of whom they are dealing with, they only had sixteen arc lights last year, and they have now given us an order for double that number. We are carrying that order out with an efficient staff and proper instruments, so that the sort of slipshod way in which it was done before will not recur in the management of your board of directors. Having obtained that position at Waverley, I consider we have got the gate of Edinburgh.

Mr. Walker: Is the order for a term of years or for a series of years?

Mr. Dickson: We have made the bargain as well as we could for several years. Of course you cannot get the railway companies to do as you will. There, the same as here, they make a compact, and say, "We will see that satisfactorily carried out for a certain number of years first."

Mr. Walker: And they can continue or discontinue the light altogether, I suppose?

Mr. Dickson: I think we are all friends here; but there are numbers of competitors watching us in Scotland, and it would not be judicious to tell you all that I could tell you here. I think the directors are doing their very best, and we do not wish to say too much to benefit our critics in the north. In obtaining the lighting of the Waverley Station, with our powerful engine we have ability to light up Princes Street, and a good deal more. We have drafts and estimates for Inverness, and for Dundee and Arbroath Stations. We have estimates for Tay Bridge, and are going into them. If we can only sufficiently see our way to save ourselves from loss and get an advertisement for our centre, and from that centre light other places near, I think we can see our way to a good business. We were told by the previous speaker that we cannot compete with gas, but I say we shall soon be put in the same position as the gas companies. Take Princes Street or Cheapside and say to a gas company, "Will you light up this street, and tell us the cost?" For twenty lamps perhaps you will have to pay twenty-one shillings per 1,000 feet. Your next neighbour perhaps only pays a few shillings, but there it is inside the houses. When we get inside the houses I trust the electric light will be as successful as the most far-seeing people expect In regard to the Oriental Storage Company, it has been stated that they having the storage batteries, were in a position to do more than we have done. But they have to pay for it, and I cannot see that in the present initial stage of batteries it is right to rush in and buy up anything that can be got (hear, hear). We have reserved our opinion and our money and are ready to take advantage of the best storage battery we can get. We have the money and I hope the brains to make a bargain, and when once we get inside the houses, we shall be able to do a business. No one who has read the evidence given before the parliamentary committee can have the slightest doubt about that (hear). I may say in touching upon these storage batteries that we have been in treaty for a number of months past for the best one standing in the market, and which I understand comprehends all the five best patents known, and it is the same as the Storage Company have. I think we have done no harm whatever by the delay. As regards what was said about the noble chairman, I am sorry he is not present. He takes an earnest interest in our company's welfare, and there is no one who, as an amateur, knows more of electricity than he does. When he went to the House of Lords, on the day when the Electric Lighting Bill was amended, he went there thoroughly determined to have—what had never been attempted by any one else—those two objectionable clauses altered, No. 2 and No. 7; and I may say that, both to his personal position in the House of Lords, and to the influence he brought to bear on his colleagues there, there is in a great measure due the fact that we have seven years instead of five for licences, and twenty-one instead of fifteen for provisional orders. That will allow us to feel about and see what we are doing, so that when the twenty-one years are over we may not be called upon, as we should at the fifteen, to sell our articles as old metal. I hope when Parliament meets next Session the two clauses now reading in opposition to each other will be put right, thus showing us where we stand. I think, meanwhile, the Bill as we have it is a good one to go on with, and the fact that we have not gone on more rapidly already is to be attributed to our not having the Bill. We could not do it, and had better let our money be at the bank at interest (hear, hear). Now we have the ability to take up streets instead of going and hanging wires overhead, making the most extraordinary state of things everywhere. We have now a bill which I think will do us very well for the present, and I believe your directors have the interests of our shareholders at heart; and I take it there is no place for our business like Scotland, where we can get such cheap coal, and if we can only make a central station as I have explained, we can produce the light, I think, very much cheaper than it can be produced here. The item of coal is one of great

importance in regard to the working of the engines and the machinery at all the factories. With water power available at every castle in the North, every mill wheel at the end of the village, if we use our centres well and do not expect too much, we have, I think, a fair prospect of doing as good business as have most things which are brought before us.

In reply to a further question from Mr. Walker, in regard to the selling of concessions.

Mr. Dickson explained that there was no use in their acting differently from what they had. Broker after broker came asking for concessions, but to have granted them would simply have been to prostitute their position. The matter of the sale of concessions they had still before them.

Mr. Wm. Ladd said that although unaccustomed to speak in public, he felt he would like to say a few words to give them confidence in the property in which they had invested their momey. He was an old electrican, and one of the pioneers of the electric light, therefore he flattered himself that he knew something of the different machines and different systems at present in vogue. The Brush machine he believed, in considering all the other systems, was very far in advance of every other for large lighting, he meant for extensive districts. There was no machine that could send a current so far as the Brush machine. There was no other machine that could give them 40 lights in one circuit. There was no other machine to compare with it for economy; he said economy, and he meant it. If they wanted one or two lights there were other machines that would compare with it, but if they wanted to light streets, or houses, there was no other machine in existence that would take so many lights; and although the price of the machine might appear to be somewhat high, yet the price of the machine was far below any other when they came to lighting a town or a large number of streets. Forty lights from one machine meant two wires, or rather one wire, going through the whole of those 40 lights and back to the machine; whereas in other systems, what you require for large lighting, you require a machine for each lamp, and that meant a great expense—more than was apparent at first sight, because they needed separate wires for each light and back again. From those lights on the Embankment, for instance, he believed that the Brush system would have given a better light and a greater light for the cost of what it had cost them for wires. Scotland was a splendid district for the light because of the water power that could be utilised. What must tell somewhat against Scotland, however, was that the Scotch people were scarcely educated up to the advantages of the electric light, and they had to educate them as yet. What he was anxious to do was to light up Glasgow, or some large place like that. Put out all the lights in the streets, and let the Scotchmen see what this company had got. There was nothing said in the prospectus with regard to accumulators. The gentleman who spoke just now would seem to say that he had been imposed upon by the prospectus. The gentleman ought to have made himself acquainted with all the ins and outs of the company. If he did not understand it, he ought not to blame any one else. It was unfortunate for the directors that there was such a rush for shares in this company; it gave them a great deal of work and caused a great deal of dissatisfaction amongst the public. Not a single director, he might say, appropriated more than one hundred shares to himself, although some applied for five hundred. They reduced their number in consequence of the number applied for. He hoped they would go on and prosper; and he was glad they had not sold concessions. He did not say they would not sell concessions, but the reaction that had come upon electric light now was affecting this company in the price of its shares, which was always the case when there was a great cry for anything.

A Voice: They are worth 17s. 6d. now.

Another Shareholder asked if any one could take the Brush system away from this company. Was it certainly theirs?

Mr. Ladd: Most decidedly, so far as Scotland is concerned. Mr. Ladd added that there was one thing he had forgotten to mention, and that was with reference to accumulators. He was a director of the Electric Light and Power Company, which had the entire lighting of the United Kingdom, and he should do all in his power for the benefit of this company; and if it could be arranged satisfactorily he was sure he would do all in his power in the matter. The Brush machine was adapted for the storage batteries, because they could have a machine in one district and send a charge along the whole street, and charge the storage batteries for the lighting of the houses.

Another Shareholder: Are you in negotiation for the use of the Sellon-Volckmar accumulator? Are the vendors allowed to dispose of their 8,000 shares?

The Chairman: The same as in any other company.

The Shareholder: With regard to the shares I hold, I should like to say I applied for shares when there were none to be had, and I bought those which I hold, so that the remarks made by Mr. Ladd are not fair. I had the prospectus before me.

Mr. Dickson said there were many accumulators before them, and he must decline to answer the question. The board were considering their merits, and he thought the shareholders had better let the question alone.

In reply to another question the chairman said that applications for shares were so large that they were obliged to cut down every one.

Mr. Dickson added that all the Brush companies had joined a conference, meeting monthly, to discuss the interests of the Brush patents, and they had taken issue on certain points. They had agreed on many points, by which they had obtained considerable concessions, and they were an earnest of what was to come. They were watching in earnest upon these matters, and pulling together with a will, so as to keep themselves well in front of their opponents everywhere.

Mr. Walker, who remarked that he was doubly unfortunate, for he bought some of his shares at a premium of between £2 and £3, and they were now worth 17s. 6d., proposed a vote of thanks to the chairman for presiding and the satisfactory manner in which he had red the questions, which was seconded by Mr. Newton, and ceedings terminated.

THE ELECTRIC CARBON, STORAGE, AND APPARATUS MANUFACTURING COMPANY OF SCOTLAND (LIMITED).

On Wednesday last, under the presidency of Mr. W. P. Hope, of Leith, the chairman of the company, the statutory meeting of the shareholders of the above-named company was held at Cannon Street Hotel.

The notice convening the meeting having been read by the secretary, Mr. Ernest Terreneau,

The Chairman said: You have heard the notice convening the meeting. It pretty well explains the cause of this meeting. It is simply a statutory meeting, to fall in with the law of limited liability companies, and, finding myself in the chair in the absence of Mr. Ratcliff, I have to explain that we have got possession of the premises at Leith, and we have been busy getting the necessary tools placed in those premises, and are now partially manufacturing carbons, in the hope of being able to begin manufacturing dynamo lamps within a few weeks of this time. We have 171 shareholders upon our list, holding 28,117 shares. The applications for shares—this company coming out late, when the electric *furore* was at its height—were smaller than were anticipated, but were sufficient to warrant the directors in going forward to allotment, especially as they had an offer for the sale of the storage shares which form part of the property to be handed over to this company at a price which induced them to part with them at once. Having made arrangements of settlement of property satisfactory to themselves, and having capital available for any extension of business, the board thought it wise to go on to allotment, and go forward with small capital, watching the event of electricity, and watching the future of it, believing we have a great deal yet to learn, believing we have a great deal we don't know to-day that we shall know in a month or two hence. We have no expensive patents, and no sums of money due for any system; we are simply waiting with a well organised system to take advantage of the time when the best electric machine will be before the company, and then to go forward. So far as we have gone in the direction of carbons, we have succeeded in producing an article which is as good as any yet before the public. Our prospects are very assuring. We have proposals from the continent and from various parts of this country for the manufacture of plant, when we are in a position to take it up. The demand for electric appliances such as we aim at producing, which is a good yet cheap article, will, we believe, be very encouraging to the public. We are going in to encourage the public in cheap electric appliances, and I believe in a very short time we shall have quite as much work as we can do. Many of the companies which have come before the public lately have savoured more of the kind which the Stock Exchange have more interest in than the company I am speaking of. A Stock Exchange quotation we do not intend to move for, seeing that our capital is insufficient. Those who invested money in this company will, with a little patience, find that something better than stock which may be bought and sold at the prices of the day. Owing to the delay in placing our machinery we have to-day to point more to what we intend to do rather than to what we have done. I hope next time we meet you that we shall have something more tangible to lay before you. We have some of our carbons here (on the table), which are at the disposition of the shareholders.

Dr. Rosenthal: I should like to ask whether any orders have been received already.

The Chairman: I think I explained in my opening remarks that we are only now in a position to receive orders, in consequence of delay in fixing our machinery.

Dr. Rosenthal asked if, when the money had been paid to the vendors, whether there would be enough capital to carry on the manufacturing.

The Chairman: I am glad to be able to give you that information, although I did state it in what I said before. I said that the directors were satisfied with the arrangements they had made with the vendors to forego their payment for a while, that they now had enough capital to carry on business, and to meet any increase of work for the next twelve months. We have already promises of work for several companies when we are ready to supply them; not exactly their orders, but promises to supply them with what they may require.

No further questions being asked, Mr. J. D. Fraser proposed a vote of thanks to the chairman, which concluded the proceedings.

Telegrams for Egypt.—It is officially announced that the Eastern Telegraph Company has established cable communication with Port Said, and telegrams for that place can be accepted, but at the sender's risk only. The charges are 2s. a word.

Cables Repaired.—Notice is given that the cable of the Paris and New York Telegraph Company, and the cable between Rio Grande do Sul and Monte Video, are repaired.

Brush Midland Electric Light and Power Company, Limited.—Mr. James Whitehead (chairman) and Mr. Augustus A. Stenger have resigned their seats at the board of this company.

Quotations have been granted to the Australasian Electric Light, Power and Storage Company, shares; the British Insulite Company, Limited, shares; and Swan United Electric Light Company, shares.

THE TELEGRAPHIC JOURNAL AND

Electrical Review.

VOL. XI.—No. 248.

MILITARY TELEGRAPH STATIONS IN BALLOONS.

Now that the friendly relations between the interior of Egypt and the world have been suspended and diplomatic negotiations are supplemented by the more telling speeches of heavy ordnance, telegraphic communication with the extensive system of Egyptian land lines has naturally ceased. The formerly friendly mission of the telegraph will for the present be used for a more serious object, viz., that of war.

One of the first operations, two opposing armies have to perform, consists in strengthening their own positions and in ascertaining the strength and position of the adversary. This latter object is generally attained by reconnoitering expeditions and by skirmishing and sham attacks, trying either to reach an eminence from whence a better view of the enemy's position may be obtained, or to force the enemy to show his strength.

A less sanguinary and perhaps more efficient mode of ascertaining the enemy's position can be used, viz., captive balloons, connected with the ground by telegraph cables; the aeronaut is thus enabled to communicate his observations to headquarters immediately, not only during a reconnaissance, but also during action. It is to this kind of aerial telegraph station that we wish to draw attention at present.

Balloons were used for reconnoitering purposes as early as the year 1794, during the wars of the French Revolution, and with great success. Two companies of aeronauts were then organised by the French, who used war-balloons at Fleurs, Maubeuge, Charleroi, Mannheim, Ehrenbreitenstein, &c. These balloons were not employed as couriers, but for reconnoitering an enemy, and sometimes the flag-signal telegraph was used. Balloon ascents were also made for the purpose of observing an enemy's movements during a battle, and thus took part in the tactical operations of the engagement.

Colonel Coutelle observed and reported, in June, 1794, from a war-balloon station, the operations of the battle of Fleurs, and the French Academy of Science, convinced of the value of such stations for military reconnoitering, recommended the general introduction of balloons for war purposes. The result was that during the same year a military aeronautical school was created in Meudon under the able direction of the celebrated aeronaut, M. Guyton de Morveau and Colonel Coutelle.

Notwithstanding these attempts, war ballooning little occupied the minds of military men from the beginning of this century until 1859, during the Crimean War, when a balloon was again tried, unfortunately, however, without any valuable results being obtained for the military operations.

To North America is due the honour of having given this half-forgotten companion of modern warfare a practical and new application. We can do no better than quote here from Mr. W. Plum's valuable book "The Military Telegraph," just published in Chicago. Mr. Plum, who was an active and distinguished officer of the American Field Telegraph Corps, says: "War balloons were used in the United States army on the Potomac and during the Peninsular campaign. On all such reconnaissances the balloon was held by ropes, and on several occasions electrical telegraphic connection was kept up with the aeronaut in the sky. This was first accomplished June 17th, 1861, when the War Department, in Washington, was placed in instant communication with Prof. Lowe, who, from his 'high estate,' caused the operator at his side to telegraph to the President of the United States:—

"SIR,—The point of observation commands an area of 50 miles in diameter. The city, with its girdle of encampments, presents a superb scene. I take great pleasure in sending you the first despatch ever telegraphed (electrically) from an aerial station and in acknowledging my indebtedness to your encouragement for the opportunity of demonstrating the availability of the science of aeronautics in the military service of the country.

"Yours respectfully,
"(Signed), T. S. C. LOWE.

"Operator C. T. Brown ascended from Pohick Church, Virginia, with Prof. Wise, and also communicated to the War Department. John La Mountain, another professional aeronaut, made ascents accompanied by General Fitz John Porter . . . . ."

The history of the North American war supplies a series of most valuable facts where balloon telegraph stations took part in the tactical operations of military engagements, and not seldom considerably contributed to the development and final success of the battle. But not only this; the Americans also tried, and with tolerable success, to obtain photographic plans of the enemy's positions taken from their telegraph balloon stations. Thus the country between Richmond, Manchester, and Chikahoming, with its batteries and troops, was photographed.

At the battle of Richmond an outpost telegraph station, placed in a balloon, captive at a height of 300 yards, was in telegraphic communication with headquarters during the whole engagement. General McClellan received immediate information from the balloon of all movements of the enemy, and was thus enabled to issue timely and correct orders to his generals, Heinselmann and Summer, for a simultaneous attack of the enemy from various directions. It is generally acknowledged that the conquest of Richmond and the complete victory of the North army was considerably due to the valuable information received from the balloon outpost telegraph station.

The next balloon reconnaissance was carried out in June, 1867, during the Paraguayan war by Brazil, which country, by the way, claims the invention of the balloon for her countryman Don Guzman, who ascended in a balloon as early as 1736 in presence of John V., the King of Portugal. Mr. von Treuenfeld, who commanded the Paraguayan field telegraph corps, says, in his book on "War Telegraphy," that the Brazilian balloon reconnoitred the fortified positions at Tuyuti and Tuyucué from a height of 200 metres, being fastened to a cable and carried along the enemy's lines by soldiers. The ascents were accompanied by staff officers, who not only drew plans of the hitherto unknown fortific-

tions, but also counted the 106 guns and three mortars, which a few days later were to be attacked.

During the Franco-German war the French army obtained great assistance through the employment of war-balloons as couriers of military orders, news, &c. Suffice it to say that from September 23rd, 1870, to January 28th, 1871, sixty-two balloons left Paris, fifty-four of which, sent out by the Post-office Department, took 2,500,000 letters, weighing ten tons. Stationary balloons (ballons captifs) were used for reconnoitering purposes, fitted out as Morse telegraph stations, and were connected with the semi-permanent field lines and the headquarters of the commander. The first of these aerial French telegraph stations ascended on November 21st, 1870, at the camp of Gidy, and on December 7th, 1870, a military aeronautical troop was formed and incorporated into the French army, which carried five balloons, to the front of the Loire army. Other balloons operated with the East army at Besançon, and with the North army at Amiens.

It is to be regretted that the information obtained by the French reconnoitering balloon stations during the Franco-German war was not in proportion to the enormous efforts and patriotic devotion of the promoters and troop of the war-balloons. This is by no means an argument against the efficiency of either of them, but only a too natural consequence of want of time for proper organisation. The rapid march of military events during the Franco-German war made the thorough organisation of a balloon service impossible, which, had it been prepared in time of peace, would undoubtedly have been of great service to the French army.

The present intimate connection between French military aeronauts and the Académie d'Aérostation Météorologique sufficiently proves that the French army learned a lesson from their experiences of 1870.

In spite of many recommendations, since 1854, from Mr. Henry Coxwell, the venerable parent of English aeronautics, urging the introduction of balloon signalling stations for reconnoitering purposes into our army equipment, little was tried, and less adopted, for many years. The decision of the War Office was thus hailed with general satisfaction by the army when, in September, 1880, a whole company of the Royal Engineers were detailed for instruction in the art of war-ballooning. Seeing the service entrusted to such distinguished officers as Captain Elsdale, R.E., Lieutenants Nare, Noel, and Anstruther, all of the Royal Engineers, and Captain Templer, of the Royal Edmonton Rifle Militia, strong anticipations existed that the field-telegraph soldier of the C Division of Aldershot Royal Engineers would soon, in an airy balloon station, replace his skirmishing and exposed comrades on *terra firma*. Such anticipations were further strengthened by balloon drills performed by sappers, under the direction of Captain Elsdale and Captain Templer, before General Turner, General Philpott, Admiral Boyes, and other officers, demonstrating the high efficiency of the portable captive balloon with all its newly-invented gear of hydrogen generating apparatus, balloon car, engineers' transport waggon, &c. At a height of about 200 ft. the balloon was drawn about to illustrate the facility with which balloons can be transported to eligible points, and even telegraph lines and railway bridges were crossed with ease by the use of duplicate towing cables. Captain Elsdale, together with Corporal Joliffe and Corporal Thomson, carried on communication from the balloon by means of flag-signalling as well as by the telephone.

Still more promising were these experiments when the Secretary of State for War ordered balloons to be used during the manœuvres at the Brighton review. The ballooning party, consisting of two officers, nine non-commissioned officers and sappers, proceeded to Brighton with two balloons and all necessary equipments. The balloon "Crusader" was inflated and conveyed in safety across a difficult piece of ground to its position, occupied by the outposts of the Lewes force. The distance traversed being about two miles and a half, including the crossing of a tidal river, railway, and telegraph wires. Captain Norton, aide-de-camp, accompanied Captain Elsdale in the balloon, which was sent up about 1,100 ft. These officers were provided with maps of the ground on which it was proposed to make rough sketches of the enemy's positions for the information of the general officer commanding the Lewes forces. Captain Templer succeeded in moving the wagon below, with the balloon attached, at a very rapid pace through the intervals between the advancing battalions. Captain Elsdale reported that when the weather cleared a most excellent view of every man and movement below was obtained. When the troops were dismissed the waggon retired at a gallop, with balloon attached, and returned to Lewes without difficulty. Captain Elsdale thus sums up the valuable experience gained on that occasion: "I would respectfully submit for consideration that the following points would appear to have been established. A balloon, in fairly favourable weather, can be conveyed captive over any ground accessible to infantry to the required position for observation. It can be moved from time to time, as required in the course of the operations, to any other suitable point . . . . . and it seems probable that valuable observations might from time to time be made at all periods of the operations."

Taking all the historical facts together, which naturally are only mentioned here in an exceedingly condensed form, and returning to our subject, military reconnaissances in front of the newly-erected and unknown Egyptian fortifications, we are inclined to think, that a thorough review from a balloon telegraph station, at a height of 300 yards, would not only be a successful mode of reconnoitering, but also a highly interesting repetition of an experiment in scientific strategy, which had so often been successfully carried out at the balloon-drilling grounds and during the Brighton review.

THE BRITISH ASSOCIATION.

THE meeting of the present year, which was inaugurated on Wednesday, the 23rd inst., is the fifty-second assemblage of the members of the British Association. Southampton has before had the honour of being the selected centre to which the eminent men of science belonging to this association annually journey. Electrical science should naturally have a greater share of attention than in previous years, for its importance is almost daily becoming more and more apparent. The President of the year, Dr. C. W. Siemens, is one of our leading authorities on this subject, but he does not go far beyond a recapitulation of known facts in his address. He, however, makes several suggestions, and has covered a vast amount of ground. What he says we can accept as correct, for Dr. Siemens is not inclined

to indulge in speculative imagination. Professors Lord Rayleigh, G. D. Liveing, R. Etheridge, and A. Gamgee, preside over the respective sections of Mathematical and Physical Science (A), Chemical Science (B), Geology (C), and Biology (D).

Sections (E), Geography; (F), Economic Science and Statistics; and (G), Mechanical Science, have respectively as Presidents, Sir R. Temple, Bart., Right Hon. G. Sclater-Booth, M.P., and John Fowler, Esq., C.E. The General Treasurer of the Association is Professor A. W. Williamson, of University College, London; and the Secretary is Professor T. G. Bonney.

THE PRESIDENT'S ADDRESS.

In venturing to address the British Association from this chair, I feel that I have taken upon myself a task involving very serious responsibility. The Association has for half a century fulfilled the important mission of drawing together, once every year, scientists from all parts of the country for the purpose of discussing questions of mutual interest, and of cultivating those personal relations which aid so powerfully in harmonising views, and in stimulating concerted action for the advancement of science.

A sad event casts a shadow over our gathering. While still mourning the irreparable loss science had sustained in the person of Charles Darwin, whose bold conceptions, patient labour, and genial mind made him almost a type of unsurpassed excellence, telegraphic news reached Cambridge, just a month ago, to the effect that our honorary secretary, Professor F. M. Balfour, had lost his life during an attempted ascent of the Aiguille Blanche de Penteret. Although only thirty years of age, few men have won distinction so rapidly and so deservedly. After attending the lectures of Michael Foster, he completed his studies of Biology under Dr. Anton Dohrn at the Zoological Station of Naples in 1875. In 1878 he was elected a Fellow, and in November last a member of Council of the Royal Society, when he was also awarded one of the royal medals for his embryological researches. Within a short interval of time Glasgow University conferred on him their honorary degree of LL.D., he was elected President of the Cambridge Philosophical Society, and after having declined very tempting offers from the Universities of Oxford and Edinburgh, he accepted a professorship of Animal Morphology created for him by his own university. Few men could have borne without hurt such a stream of honourable distinctions; but in young Balfour genius and independence of thought were happily blended with industry and personal modesty; these won for him the friendship, esteem, and admiration of all who knew him.

Since the days of the first meeting of the Association in York in 1831, great changes have taken place in the means at our disposal for exchanging views, either personally or through the medium of type. The creation of the railway system has enabled congenial minds to attend frequent meetings of those special societies which have sprung into existence since the foundation of the British Association, amongst which I need only name here the Physical, Geographical, Meteorological, Anthropological, and Linnean, cultivating abstract science, and the Institution of Mechanical Engineers, the Institution of Naval Architects, the Iron and Steel Institute, the Society of Telegraph Engineers and of Electricians, the Gas Institute, the Sanitary Institute, and the Society of Chemical Industry, representing applied science. These meet at frequent intervals in London, whilst others, having similar objects in view, hold their meetings at the University towns, and at other centres of intelligence and industry throughout the country, giving evidence of great mental activity, and producing some of those very results which the founders of the British Association wished to see realised. If we consider further the extraordinary development of scientific journalism which has taken place, it cannot surprise us when we meet with expressions of opinion to the effect that the British Association has fulfilled its mission, and should now yield its place to those special societies it has served to call into existence. On the other hand, it may be urged that the brilliant success of last year's anniversary meeting, enhanced by the comprehensive address delivered on that occasion by my distinguished predecessor in office, Sir John Lubbock, has proved, at least, that the British Association is not dead in the affections of its members, and it behoves us at this, the first ordinary gathering in the second half century, to consider what are the strong points to rely upon for the continuance of a career of success and usefulness.

If the facilities brought home to our doors of acquiring scientific information have increased, the necessities for scientific inquiry have increased in a greater ratio. The time was when science was cultivated only by the few, who looked upon its application to the arts and manufactures as almost beneath their consideration; this they were content to leave in the hands of others, who, with only commercial aims in view, did not aspire to further the objects of science for its own sake, but thought only of benefiting by its teachings. Progress could not be rapid under this condition of things, because the man of pure science rarely pursued his inquiry beyond the mere enunciation of a physical or chemical principle, whilst the simple practitioner was at a loss how to harmonise the new knowledge with the stock of information which formed his mental capital in trade.

The advancement of the last fifty years has, I venture to submit, rendered theory and practice so inter-dependent that an intimate union between them is a matter of absolute necessity for our future progress. Take, for instance, the art of dyeing, and we find that the discovery of new colouring matters derived from waste products, such as coal-tar, completely changes its practice, and renders an intimate knowledge of the science of chemistry a matter of absolute necessity to the practitioner. In telegraphy and in the new arts of applying electricity to lighting, to the transmission of power, and to metallurgical operations, problems arise at every turn, requiring for their solution not only an intimate acquaintance with, but a positive advance upon, electrical science as established by purely theoretical research in the laboratory. In general engineering the mere practical art of constructing a machine so designed and proportioned as to produce mechanically the desired effect, would suffice no longer. Our increased knowledge of the nature of the mutual relations between the different forms of energy makes us see clearly what are the theoretical limits of effect; these, although beyond our absolute reach, may be looked upon as the asymptotes to be approached indefinitely by the hyperbolic course of practical progress, of which we should never lose sight. Cases arise, moreover, where the introduction of new materials of construction, or the call for new effects, renders former rules wholly insufficient. In all these cases practical knowledge has to go hand in hand with advanced science in order to accomplish the desired end.

Far be it from me to think lightly of the ardent students of nature, who, in their devotion to research, do not allow their minds to travel into the regions of utilitarianism and of self-interest. These, the high priests of science, command our utmost admiration; but it is not to them that we can look for our current progress in practical science, much less can we look for it to the "rule of thumb" practitioner, who is guided by what comes nearer to instinct than to reason. It is to the man of science, who also gives attention to practical questions, and to the practitioner, who devotes part of his time to the prosecution of strictly scientific investigations, that we owe the rapid progress of the present day, both merging more and more into one class, that of pioneers in the domain of nature. It is such men that Archimedes must have desired when he refused to teach his disciples the art of constructing his powerful ballistic engines, exhorting them to give their attention to the principles involved in their construction, and that Telford, the founder of the Institution of Civil Engineers, must have had in his mind's eye when he defined civil engineering as "the art of directing the great sources of power in nature."

These considerations may serve to show that although we see the men of both abstract and applied science group themselves in minor bodies for the better prosecution of special objects, the points of contact between the different branches of knowledge are ever multiplying, all tending to form part of a mighty tree—the tree of modern science—under whose ample shadow its cultivators will find it both profitable and pleasant to meet, at least once a year; and considering that this tree is not the growth of one country only, but spreads both its roots and branches far and wide, it appears desirable that at these yearly gatherings other nations should be more fully represented than has hitherto been the case. The subjects discussed at our meetings are without exception of general interest, but many of them bear an international character, such as the systematic collection of magnetic, astronomical, meteorological, and geodetical observations, the formation of a universal code for signalling at sea, and for distinguishing lighthouses, and especially the settlement of scientific nomenclatures and units of measurement, regarding all of which an international accord is a matter of the utmost practical importance.

As regards the measures of length and weight it is to be regretted that this country still stands aloof from the movement initiated in France towards the close of last century; but, considering that in scientific work metrical measure is now almost universally adopted, and that its use has been already legalised in this country, I venture to hope that its universal adoption for commercial purposes will soon follow as a matter of course. The practical advantages of such a measure to the trade of this country would, I am convinced, be very great, for English goods, such as machinery or metal rolled to current sections, are now almost excluded from the continental market, owing to the unit measure employed in their production. The principal impediment to the adoption of the metre consists in the strange anomaly that although it is legal to use that measure in commerce, and although a copy of the standard metre is kept in the Standards' Department of the Board of Trade, it is impossible to procure legalised rods representing it, and to use a non-legalised copy of a standard in commerce is deemed fraudulent. Would it not be desirable that the British Association should endeavour to bring about the use in this country of the metre and kilogramme, and as a preliminary step, petition the Government to be represented on the International Metrical Commission, whose admirable establishment at Sèvres possesses, independently of its practical work, considerable scientific interest as a well-found laboratory for developing methods of precise measurement?

Next in importance to accurate measures of length, weight, and time, stand, for the purposes of modern science, those of electricity.

The remarkably clear lines separating conductors from non-conductors of electricity, and magnetic from non-magnetic substances, enable us to measure electrical quantites and effects with almost mathematical precision; and although the ultimate nature of this, the youngest scientifically investigated form of energy, is yet wrapt in mystery, its laws are the most clearly established, and its measuring instruments (galvanometers, electrometers, and magnetometers), are amongst the most accurate in physical science. Nor could any branch of science or industry be named in which electrical phenomena do not occur, to exercise their direct and important influence.

If, then, electricity stands foremost amongst the exact sciences, it follows that its unit measures should be determined with the utmost accuracy. Yet, twenty years ago, very little advance had been made towards the adoption of a rational system. Ohm had, it is true, given us the fixed relations existing between electromotive force, resistance and quantity of current; Joule had established the dynamical equivalent of heat and electricity, and Gauss and Weber had proposed their elaborate system of absolute magnetic measurement. But these invaluable researches appeared only as isolated efforts, when, in 1862, the Electric Unit Committee was appointed by the British Association, at the instance of Sir William Thomson,

and it is to the long-continued activity of this Committee that the world is indebted for a consistent and practical system of measurement, which, after being modified in details, received universal sanction last year by the International Electrical Congress assembled at Paris.

At this Congress, which was attended officially by the leading physicists of all civilised countries, the attempt was successfully made to bring about a union between the statical system of measurement that had been followed in Germany and some other countries, and the magnetic or dynamical system developed by the British Association, also between the geometrical measure of resistance, the (Werner) Siemens unit, that had been generally adopted abroad, and the British Association unit intended as a multiple of Weber's absolute unit, though not entirely fulfilling that condition. The Congress, while adopting the absolute system of the British Association, referred the final determination of the unit measure of resistance to an International Committee, to be appointed by the representatives of the several Governments; they decided to retain the mercury standard for reproduction and comparison, by which means the advantages of both systems are happily combined, and much valuable labour is utilised; only, instead of expressing electrical quantities directly in absolute measure, the Congress has embodied a consistent system, based on the ohm, in which the units are of a value convenient for practical measurements. In this, which we must hereafter know as the "practical system," as distinguished from the "absolute system," the units are named after leading physicists, the Ohm, Ampère, Volt, Coulomb, and Farad.

I would venture to suggest that two further units might, with advantage, be added to the system decided on by the International Congress at Paris. The first of these is the unit of magnetic quantity or pole. It is of much importance, and few will regard otherwise than with satisfaction the suggestion of Clausius that the unit should be called a "Weber," thus retaining a name most closely connected with electrical measurements, and only omitted by the Congress in order to avoid the risk of confusion in the magnitude of the unit current with which his name had been formerly associated.

The other unit I should suggest adding to the list is that of power. The power conveyed by a current of an Ampère through the difference of potential of a Volt is the unit consistent with the practical system. It might be appropriately called a Watt, in honour of that master mind in mechanical science James Watt. He it was who first had a clear physical conception of power, and gave a rational method of measuring it. A Watt, then, expresses the rate of an Ampère multiplied by a Volt, whilst a horse-power is 746 Watts, and a Cheval de Vapeur 735.

The system of electro-magnetic units would then be:—

(1) Weber,	the unit of	magnetic quantity	$= 10^8$	C.G.S. Units.
(2) Ohm	,,	,, resistance	$= 10^9$	,,
(3) Volt	,,	,, electromotive force	$= 10^8$	,,
(4) Ampère	,,	,, current	$= 10^{-1}$	,,
(5) Coulomb	,,	,, quantity	$= 10^{-1}$	,,
(6) Watt	,,	,, power	$= 10^7$	,,
(7) Farad	,,	,, capacity	$= 10^{-9}$	,,

Before the list can be looked upon as complete two other units may have to be added, the one expressing that of magnetic field, and the other of heat in terms of the electromagnetic system. Sir William Thomson suggested the former at the Paris Congress, and pointed out that it would be proper to attach to it the name of Gauss, who first theoretically and practically reduced observations of terrestrial magnetism to absolute measure. A Gauss will, then, be defined as the intensity of field produced by a Weber at a distance of one centimetre; and the Weber will be the absolute C.G.S. unit strength of magnetic pole. Thus the mutual force between two ideal point-poles, each of one Weber strength held at unit distance asunder, will be one dyne; that is to say, the force which acting for a second of time on a gramme of matter, generates a velocity of one centimetre per second.

The unit of heat has hitherto been taken variously as the heat required to raise a pound of water at the freezing-point through 1° Fahrenheit or Centigrade, or, again, the heat necessary to raise a kilogramme of water 1° Centigrade. The inconvenience of a unit so entirely arbitrary is sufficiently apparent to justify the introduction of one based on the electromagnetic system, viz., the heat generated in one second by the current of an Ampère flowing through the resistance of an Ohm. In absolute measure its value is 10^7 C.G.S. units, and assuming Joule's equivalent as 42,000,000, it is the heat necessary to raise 0·238 grammes of water 1° Centigrade, or, approximately, the 1-1000th part of the arbitrary unit of a pound of water raised 1° Fahrenheit and the 1-4000th of the kilogramme of water raised 1° Centigrade. Such a heat unit, if found acceptable, might with great propriety, I think, be called the Joule, after the man who has done so much to develop the dynamical theory of heat.

Professor Clausius urges the advantages of the statical system of measurement for simplicity, and shows that the numerical values of the two systems can readily be compared by the introduction of a factor, which he proposes to call the critical velocity; this, Weber has already shown to be nearly the same as the velocity of light. It is not immediately evident how by the introduction of a simple multiple, signifying a velocity, the statical can be changed into dynamical values, and I am indebted to my friend Sir William Thomson for an illustration which struck me as remarkably happy and convincing. Imagine a ball of conducting matter so constituted that it can at pleasure be caused to shrink. Now let it first be electrified and left insulated with any quantity of electricity on it. After that, let it be connected with the earth by an excessively fine wire, or a not perfectly dry silk fibre; and let it shrink just so rapidly as to keep its potential constant, till the whole charge is carried off. The velocity with which its surface approaches its centre is the electrostatic measure of the conducting power of the fibre. Thus we see how "conducting power" is, in electrostatic theory, properly measured in terms of a velocity. Weber had shown how, in electromagnetic theory, the resistance, or the reciprocal of the conducting power of a conductor, is properly measured by a velocity. The critical velocity, which measures the conducting power in electrostatic reckoning and the resistance in electromagnetic, of one and the same conductor, measures the number of electrostatic units in the electromagnetic unit of electric quantity.

Without waiting for the assembling of the International Committee charged with the final determination of the Ohm, one of its most distinguished members, Lord Rayleigh, has, with his collaborateure, Mrs. Sidgwick, continued his important investigation in this direction at the Cavendish Laboratory, and has lately placed before the Royal Society a result which will probably not be surpassed in accuracy. His redetermination brings him into close accord with Dr. Werner Siemens, their two values of the mercury unit being 0·95418 and 0·9536 of the B.A. unit respectively, or 1 mercury unit $= 0{\cdot}9413 \times 10^9$ C.G.S. units.

Shortly after the publication of Lord Rayleigh's recent results, Messrs. Glazebrook, Dodds, and Sargant, of Cambridge communicated to the Royal Society two determinations of the Ohm, by different methods; and it is satisfactory to find that their final values differ only in the fourth decimal, the figures being, according to

Lord Rayleigh .. .. 1 Ohm $= 0{\cdot}98651 \dfrac{\text{Earth Quadrant}}{\text{Second}}$

Messrs. Glazebrook, &c. .. $= 0{\cdot}986439$,,

Professor E. Wiedemann, of Leipzig, has lately called attention to the importance of having the Ohm determined in the most accurate manner possible, and enumerates four distinct methods, all of which should unquestionably be tried with a view of obtaining concordant results, because upon its accuracy will depend the whole future system of measurement of energy of whatever form.

The word Energy was first used by Young in a scientific sense, and represents a conception of recent date, being the outcome of the labours of Carnot, Mayer, Joule, Grove, Clausius, Clerk-Maxwell, Thomson, Stokes, Helmholtz, Macquorn-Rankine, and other labourers, who have accomplished for the science regarding the forces in Nature what we owe to Lavoisier, Dalton, Berzelius, Liebig, and others, as regards chemistry. In this short word Energy we find all the efforts in nature, including electricity, heat, light, chemical action, and dynamics, equally represented, forming, to use Dr. Tyndall's apt expression, so many 'modes of motion.' It will readily be conceived that when we have established a fixed numerical relation between these different modes of motion, we know beforehand what is the utmost result we can possibly attain in converting one form of energy into another, and to what extent our apparatus for effecting the conversion falls short of realising it. The difference between ultimate theoretical effect and that actually obtained is commonly called loss, but, considering that energy is indestructible, represents really secondary effect, which we obtain without desiring it. Thus friction in the working parts of a machine represents a loss of mechanical effect, but is a gain of heat, and in like manner the loss sustained in transferring electrical energy from one point to another is accounted for by heat generated in the conductor. It sometimes suits our purpose to augment the transformation of electrical into heat energy at certain points of the circuit, when the heat rays become visible, and we have the incandescence electric light. In effecting a complete severance of the conductor for a short distance, after the current has been established, a very great local resistance is occasioned, giving rise to the electric arc, the highest development of heat ever attained. Vibration is another form of lost energy in mechanism, but who would call it a loss if it proceeded from the violin of a Joachim or a Norman-Neruda?

Electricity is the form of energy best suited for transmitting an effect from one place to another; the electric current passes through certain substances—the metals—with a velocity limited only by the retarding influence caused by electric charge of the surrounding dielectric, but approaching probably under favourable conditions that of radiant heat and light, or 300,000 kilometres per second; it refuses, however, to pass through oxidised substances, glass, gums, or through gases, except when in a highly rarefied condition. It is easy therefore to confine the electric current within bounds, and to direct it through narrow channels of extraordinary length. The conducting wire of an Atlantic cable is such a narrow channel; it consists of a copper wire, or strand of wires, 5 mm. in diameter, by nearly 5,000 kilometres in length, confined electrically by a coating of gutta-percha about 4 mm. in thickness. The electricity from a small galvanic battery passing into this channel prefers the long journey to America in the good conductor, and back through the earth, to the shorter journey across the 4 mm. in thickness of insulating material. By an improved arrangement the alternating currents employed to work long submarine cables do not actually complete the circuit, but are merged in a condenser at the receiving station, after having produced their extremely slight but certain effect upon the receiving instrument. So perfect is the channel and so precise the action of both the transmitting and receiving instruments employed, that two systems of electric signals may be passed simultaneously through the same cable in opposite directions, producing independent records at either end. By the application of this duplex mode of working to the Direct United States cable, under the superintendence of Dr. Muirhead, its transmitting power was increased from 25 to 60 words a minute, being equivalent to about twelve currents or primary impulses per second. In transmitting these impulse-currents simultaneously from both ends of the line, it must not be imagined, however, that they pass each other in the manner of liquid waves belonging to separate systems; such a supposition would involve momentum in the electric flow, and although the effect produced is analogous to such an action, it rests upon totally different grounds—namely, that of a local circuit at

each terminus being called into action automatically whenever two similar currents are passed into the line simultaneously from both ends. In extending this principle of action quadruplex telegraphy has been rendered possible, although not yet for long submarine lines.

The minute currents here employed are far surpassed as regards delicacy and frequency by those revealed to us by that marvel of the present day, the telephone. The electric currents caused by the vibrations of a diaphragm acted upon by the human voice, naturally vary in frequency and intensity according to the number and degree of those vibrations, and each motor current in exciting the electro-magnet forming part of the receiving instrument, deflects the iron diaphragm occupying the position of an armature to a greater or smaller extent according to its strength. Savart found that the fundamental *la* springs from 440 complete vibrations in a second, but what must be the frequency and modulations of the motor current and of magnetic variations necessary to convey to the ear through the medium of a vibrating armature such a complex of human voices and of musical instruments as constitutes an opera performance? And yet such performances could be distinctly heard and even enjoyed as an artistic treat by applying to the ears a pair of the double telephonic receivers at the Paris Electrical Exhibition, when connected with a pair of transmitting instruments in front of the footlights of the Grand Opera. In connection with the telephone, and with its equally remarkable adjunct the microphone, the names of Reis, Graham Bell, Edison, and Hughes will ever be remembered.

Considering the extreme delicacy of the currents working a telephone, it is obvious that those caused by induction from neighbouring telegraphic line wires would seriously interfere with the former and mar the speech or other sounds produced through their action. To avoid such interference the telephone wires if suspended in the air require to be placed at some distance from telegraphic line wires, and to be supported by separate posts. Another way of neutralising inteference consists in twisting two separately insulated telephone wires together, so as to form a strand, and in using the two conductors as a metallic circuit to the exclusion of the earth; the working current will, in that case, receive equal and opposite inductive influences, and will therefore remain unaffected by them. On the other hand two insulated wires instead of one are required for working one set of instruments; and a serious increase in the cost of installation is thus caused. To avoid this Mr. Jacob has lately suggested a plan of combining pairs of such metallic circuits again into separate working pairs, and these again with other working pairs, whereby the total number of telephones capable of being worked without interference is made to equal the total number of single wires employed. The working of telephones and telegraphs in metallic circuit has the further advantage that mutual volta induction between the outgoing and returning currents favours the transit, and neutralises on the other hand the retarding influence caused by charge in underground or submarine conductors. These conditions are particularly favourable to underground line wires, which possess other important advantages over the still prevailing overground system, in that they are unaffected by atmospheric electricity, or by snowstorm and heavy gales, which at not very rare intervals of time put us back to pretelegraphic days, when the letter-carrier was our swiftest messenger.

The underground system of telegraphs, first introduced into Germany by Werner Siemens in the years 1847-8, had to yield for a time to the overground system owing to technical difficulties, but it has been again resorted to within the last four years, and multiple land cables of solid construction now connect all the important towns of that country. The first cost of such a system is no doubt considerable (being about £38 per kilometre of conductor as against £8 10s. the cost of land lines); but as the underground wires are exempt from frequent repairs and renewals, and as they insure continuity of service, they are decidedly the cheaper and better in the end. The experience afforded by the early induction of the underground system in Germany was not, however, without its beneficial results, as it brought to light the phenomena of lateral induction, and of faults in the insulating coating, matters which had to be understood before submarine telegraphy could be attempted with any reasonable prospect of success.

Regarding the transmission of power to a distance the electric current has now entered the lists in competition with compressed air, the hydraulic accumulator, and the quick running rope as used at Schaffhausen to utilise the power of the Rhine fall. The transformation of electrical into mechanical energy can be accomplished with no further loss than is due to such incidental causes as friction and the heating of wires; these in a properly designed dynamo-electric machine do not exceed ten per cent., as shown by Dr. John Hopkinson, and, judging from recent experiments of my own, a still nearer approach to ultimate perfection is attainable. Adhering, however, to Dr. Hopkinson's determination for safety's sake, and assuming the same percentage in reconverting the current into mechanical effect, a total loss of 19 per cent. results. To this loss must be added that through electrical resistance in the connecting line wires, which depends upon their length and conductivity, and that due to heating by friction of the working parts of the machine. Taking these as being equal to the internal losses incurred in the double process of conversion, there remains a useful effect of $100 - 38 = 62$ per cent., attainable at a distance, which agrees with experimental results, although in actual practice it would not be safe at present to expect more than 50 per cent. of ultimate useful effect, to allow for all mechanical losses.

In using compressed air or water for the transmission of power the loss cannot be taken at less than 50 per cent., and as it depends upon fluid resistance it increases with distance more rapidly than in the case of electricity. Taking the loss of effect in all cases as 50 per cent., electric transmission presents the advantage that an insulated wire does the work of a pipe capable of withstanding high internal pressure, which latter must be more costly to put down and to maintain. A second metallic conductor is required, however, to complete the electrical circuit, as the conducting power of the earth alone is found unreliable for passing quantity currents, owing to the effects of polarisation; but as this second conductor need not be insulated, water or gas pipes, railway metals or fencing wire, may be called into requisition for the purpose. The small space occupied by the electro-motor, its high working speed, and the absence of waste products, render it specially available for the general distribution of power to cranes and light machinery of every description. A loss of effect of 50 per cent. does not stand in the way of such applications, for it must be remembered that a powerful central engine of best construction produces motive power with a consumption of two pounds of coal per horse-power per hour, whereas small engines distributed over a district would consume not less than five; we thus see that there is an advantage in favour of electric transmission as regards fuel, independently of the saving of labour and other collateral benefits.

To agriculture, electric transmission of power seems well adapted for effecting the various operations of the farm and fields from one centre. Having worked such a system myself in combination with electric lighting and horticulture for upwards of two years, I can speak with confidence of its economy, and of the facility with which the work is accomplished in charge of untrained persons.

As regards the effect of the electric light upon vegetation, there is little to add to what was stated in my paper read before Section A last year, and ordered to be printed with the report, except that in experimenting upon wheat, barley, oats, and other cereals sown in the open air, there was a marked difference between the growth of the plants influenced and those uninfluenced by the electric light. This was not very apparent till towards the end of February, when, with the first appearance of mild weather, the plants under the influence of an electric lamp of 4,000 candle-power placed about 5 metres above the surface, devolved with extreme rapidity, so that by the end of May they stood above four feet high, with the ears in full bloom, when those not under its influence were under two feet in height, and showed no sign of the ear.

In the electric railway first constructed by Dr. Werner Siemens, at Berlin, in 1879, electric energy was transmitted to the moving carriage or train of carriages through the two rails upon which it moved, these being sufficiently insulated from each other by being placed upon well creosoted cross sleepers. At the Paris Electrical Exhibition the current was conveyed through two separate conductors making sliding or rolling contact with the carriage, whereas in the electric railway now in course of construction in the north of Ireland (which when completed will have a length of twelve miles), a separate conductor will be provided by the side of the railway, and the return circuit completed through the rails themselves, which in that case need not be insulated; secondary batteries will be used to store the surplus energy created in running downhill, to be restored in ascending steep inclines, and for passing roadways where the separate insulated conductor is not practicable. The electric railway possesses great advantages over horse or steam-power for towns, in tunnels, and in all cases where natural sources of energy, such as waterfalls, are available; but it would not be reasonable to suppose that it will in its present condition compete with steam propulsion upon ordinary railways. The transmission of power by means of electric conductors possesses the further advantage over other means of transmission that, provided the resistance of the rails be not very great, the power communicated to the locomotive reaches its maximum when the motion is at its minimum—that is, in commencing to work, or when encountering an exceptional resistance—whereas the utmost economy is produced in the normal condition of working when the velocity of the power-absorbing nearly equals that of the current-producing machine.

The deposition of metals from their solutions is perhaps the oldest of all useful applications of the electric current, but is only in very recent times that the dynamo current has been practically applied to the refining of copper and other metals, as now practised at Birmingham and elsewhere, and upon an exceptionally large scale at Ocker, in Germany. The dynamo machine there employed was exhibited at the Paris Electrical Exhibition, its peculiar feature being that the conductors upon the rotating armature consisted of solid bars of copper, 30 mm. square, in section, which were found only just sufficient to transmit the large quantity of electricity of low ten .on necessary for this operation. One such machine consuming 4 horse-power deposits about 300 kilogrammes of copper per 24 hours, the motive power at Ocker is derived from a waterfall.

Electric energy may also be employed for heating purposes, but in this case it would obviously be impossible for it to compete in point of economy with the direct combustion of fuel for the attainment of ordinary degrees of heat. Bunsen and St. Claire De Ville have taught us, however, that combustion becomes extremely sluggish when a temperature of 1,800° C. has been reached, and for effects at temperatures exceeding that limit the electric furnace will probably find advantageous applications. Its specific advantage consists in being apparently unlimited in the degree of heat attainable, thus opening out a new field of investigation to the chemist and metallurgist. Tungsten has been melted in such a furnace, and 8 pounds of platinum have been reduced from the cold to the liquid condition in 20 minutes.

The largest and most extensive application of electric energy at the present time is to lighting, but considering how much has of late been said and written for and against this new illuminant, I shall here confine myself to a few general remarks. Joule has shown that if an electric current is passed through a conductor the whole of the energy lost by the current is converted into heat; or, if the resistance be localised, into radiant energy comprising heat, light, and actinic rays. Neither the low heat rays nor the ultra-violet of highest refrangibility affect the retina, and may be regarded as lost energy, the effective rays being those between the red and violet of the spectrum, which in their combination produce the effect of white light.

Regarding the proportion of luminous to non-luminous rays proceeding from an electric arc or incandescent wire, we have a mo-

valuable investigation by Dr. Tyndall, recorded in his work on "Radiant Heat." Dr. Tyndall shows that the luminous rays from a platinum wire heated to its highest point of incandescence, which may be taken at 1,700° C., formed 1-24th part of the total radiant energy emitted, and 1-10th part in the case of an arc light worked by a battery of 50 Grove's elements. In order to apply these valuable data to the case of electric lighting by means of dynamo-currents, it is necessary in the first place to determine what is the power of 50 Grove's elements of the size used by Dr. Tyndall, expressed in the practical scale of units as now established. From a few experiments lately undertaken for myself, it would appear that 50 such cells have an electromotive force of 98·5 Volts, and an internal resistance of 13·5 Ohms, giving a current of 7·3 Ampères when the cells are short-circuited. The resistance of a regulator such as Dr. Tyndall used in his experiments may be taken at 10 ohms, the current produced in the arc would be $\frac{98 \cdot 5}{13 \cdot 5 + 10 + 1} = 4$ Ampères (allowing one Ohm for the leads), and the power consumed $10 \times 4^2 = 160$ Watts; the light power of such an arc would be about 150 candles, and comparing this with an arc of 3,308 candles produced by 1,162 Watts, we find that $\left(\frac{1,162}{160}\right)$, *i.e.*, 7·3 times the electric energy produce $\left(\frac{3,308}{150}\right)$, *i.e.*, twenty-two times the amount of light measured horizontally. If, therefore, in Dr. Tyndall's arc 1-10th of the radiant energy emitted was visible as light, it follows that in a powerful arc of 3,300 candles, $\frac{1}{10} \times \frac{22 \cdot 0}{7 \cdot 3}$ or fully $\frac{1}{3}$, are luminous rays. In the case of the incandescence light (say a Swan light of 20 candle-power) we find in practice that nine times as much power has to be expended as in the case of the arc light; hence, $\frac{1}{3} \times \frac{1}{9} = $ 1-27 part of the power is given out as luminous rays, as against 1-24th in Dr. Tyndall's incandescent platinum—a result sufficiently approximate considering the wide difference of conditions under which the two are compared.

These results are not only of obvious practical value, but they seem to establish a fixed relation between current, temperature, and light produced, which may serve as a means to determine temperatures exceeding the melting point of platinum with greater accuracy than has hitherto been possible by actinimetric methods in which the thickness of the luminous atmosphere must necessarily exercise a disturbing influence. It is probably owing to this circumstance that the temperature of the electric arc as well as that of the solar photosphere has frequently been greatly over-estimated.

The principal argument in favour of the electric light is furnished by its immunity from products of combustion which not only heat the lighted apartments, but substitute carbonic acid and deleterious sulphur compounds for the oxygen upon which respiration depends; the electric light is white instead of yellow, and thus enables us to see pictures, furniture, and flowers as by daylight; it supports growing plants instead of poisoning them, and by its means we can carry on photography and many other industries at night as well as during the day. The objection frequently urged against the electric light, that it depends upon the continuous motion of steam or gas engines, which are liable to accidental stoppage, has been removed by the introduction into practical use of the secondary battery; this, although not embodying a new conception, has lately been greatly improved in power and constancy by Planté, Faure, Volckmar, Sellon, and others, and promises to accomplish for electricity what the gas-holder has done for the supply of gas and the accumulator for hydraulic transmission of power.

It can no longer be a matter of reasonable doubt, therefore, that electric lighting will take its place as a public illuminant, and that even though its cost should be found greater than that of gas, it will be preferred for the lighting of drawing-rooms and dining-rooms, theatres and concert-rooms, museums, churches, warehouses, show-rooms, printing establishments, and factories, and also the cabins and engine-rooms of passenger steamers. In the cheaper and more powerful form of the arc light, it has proved itself superior to any other illuminant for spreading artificial daylight over the large areas of harbours, railway stations, and the sites of public works. When placed within a holophote the electric lamp has already become a powerful auxiliary in effecting military operations both by sea and land.

The electric light may be worked by natural sources of power such as waterfalls, the tidal wave, or the wind, and it is conceivable that these may be utilised at considerable distances by means of metallic conductors. Some five years ago I called attention to the vastness of those sources of energy, and the facility offered by electrical conduction in rendering them available for lighting and power supply, while Sir William Thomson made this important matter the subject of his admirable address to Section A last year at York, and dealt with it in an exhaustive manner.

The advantages of the electric light and of the distribution of power by electricity have lately been recognised by the British Government, who have just passed a Bill through Parliament to facilitate the establishment of electrical conductors in towns, subject to certain regulating clauses to protect the interests of the public and of local authorities. Assuming the cost of electric light to be practically the same as gas, the preference for one or other will in each application be decided upon grounds of relative convenience, but I venture to think that gas-lighting will hold its own as the poor man's friend.

Dr. Siemens next dealt with the question of gas, giving it as his opinion that the time was not far distant when we should all resort to gas as a heating agent on the grounds [of co]nvenience, cleanliness, and economy. He said that the quasi-monopoly so long enjoyed by gas companies has had the inevitable effect of checking progress. They seemingly gave merely the prescribed illuminating power, discouraged the invention of economical burners, and the application of gas for heating purposes was partially discountenanced. The introduction of the electric light had, however, convinced gas managers that such a policy is no longer tenable.

The President then spoke of the coal-tar industry and the discovery of the aniline dyes, and he also alluded to the importance of ammonia as a manure, for the supply of which we have to look almost exclusively to our gas-works. In speaking of the use—or rather abuse—of using raw coal for heating purposes, he stated that Professor Roberts has calculated that the soot in the pall hanging over London on a winter's day amounts to 50 tons, and that the poisonous carbonic oxide may be taken as at least five times that amount. Mr. Aitken had shown that the fine dust resulting from the imperfect combustion of coal is mainly instrumental in the formation of fog. In commenting upon the luminosity of gas, the lecturer went on to say :—

The amount of light given out by a gas flame depends upon the temperature to which the particles of solid carbon in the flame are raised, and Dr. Tyndall has shown that of the radiant energy set up in such a flame only the 1-25th part is luminous; the hot products of combustion carry off at least four times as much energy as is radiated, so that not more than one hundredth part of the heat evolved in combustion is converted into light. This proportion could be improved, however, by increasing the temperature of combustion, which may be effected either by intensified air currents or by regenerative action. Supposing that the heat of the products of combustion could be communicated to metallic surfaces, and be transferred by conduction or otherwise to the atmospheric air supporting combustion in the flame, we should be able to increase the temperature accumulatively to any point within the limit of dissociation; this limit may be fixed at about 2,300° C., and cannot be very much below that of the electric arc. At such a temperature the proportion of luminous rays to the total heat produced in combustion would be more than doubled, and the brilliancy of the light would at the same time be greatly increased. Thus improved, gas-lighting may continue its rivalry with electric lighting both as regards economy and brilliancy, and such rivalry must necessarily result in great public advantage.

In the production of mechanical effect from heat, gaseous fuel also presents most striking advantages, as will appear from the following consideration. When we have to deal with the question of converting mechanical into electrical effect, or *vice versa*, by means of the dynamo-electrical machine, we have only to consider what are the equivalent values of the two forms of energy, and what precautions are necessary to avoid losses by the electrical resistance of conductors and by friction. The transformation of mechanical effect into heat involves no losses except those resulting from imperfect installation, and these may be so completely avoided that Dr. Joule was able by this method to determine the equivalent values of the two forms of energy. But in attempting the inverse operation of effecting the conversion of heat into mechanical energy, we find ourselves confronted by the second law of thermo-dynamics, which says that whenever a given amount of heat is converted into mechanical effect, another but variable amount descends from a higher to a lower potential, and is thus rendered unavailable.

In the condensing steam engine this waste heat comprises that communicated to the condensing water, whilst the useful heat, or that converted into mechanical effect, depends upon the difference of temperature between the boiler and condenser. The boiler pressure is limited, however, by considerations of safety and convenience of construction, and the range of working temperature rarely exceeds 120° C. except in the engines constructed by Mr. Perkins, in which a range of 160° C., or an expansive action commencing at 14 atmospheres, has been adopted with considerable promise of success, as appears from an able report on this engine by Sir Frederick Bramwell. To obtain more advantageous primary conditions we have to turn to the caloric or gas engine, because in them the co-efficient of efficiency expressed by $\frac{T - T'}{T}$ may be greatly increased. This value would reach a maximum if the initial absolute temperature T could be raised to that of combustion, and T′ reduced to atmospheric temperature, and these maximum limits can be much more nearly approached in the gas engine worked by a combustible mixture of air and hydrocarbons than in the steam engine.

Assuming, then, in an explosive gas engine a temperature of 1,500° C. at a pressure of 4 atmospheres, we should, in accord[ance with] the second law of thermo-dynamics, find a temperature aft[er expan]sion to atmospheric pressure of 600° C., and therefore a work[ing range] of $1500° - 600° = 900°$, and a theoretical efficiency of [...] = about one-half, contrasting very favourably with [...] expansive condensing steam engine, in which the rang[e ...] 120° C., and the efficiency $\frac{120}{150 + 274} = \frac{2}{7}$. A good [...] engine is therefore capable of yielding as mechan[ical ...] of the heat communicated to the boiler, which [...] heat lost by imperfect combustion, and that [...]

chimney. Adding to these the losses by friction and radiation in the engine, we find that the best steam engine yet constructed does not yield in mechanical effect more than 1-7th part of the heat energy residing in the fuel consumed. In the gas engine we have also to make reductions from the theoretical efficiency, on account of the rather serious loss of heat by absorption into the working cylinder, which has to be cooled artificially in order to keep its temperature down to a point at which lubrication is possible; this together with frictional loss cannot be taken at less than one-half, and reduces the factor of efficiency of the engine to 1-4th.

It follows from these considerations that the gas or caloric engine combines the conditions most favourable to the attainment of maximum results, and it may be reasonably supposed that the difficulties still in the way of their application on a large scale will gradually be removed. Before many years have elapsed we shall find in our factories and on board our ships engines with a fuel consumption not exceeding 1 pound of coal per effective horse-power per hour, in which the gas producer takes the place of the somewhat complex and dangerous steam boiler. The advent of such an engine and of the dynamo-machine must mark a new era of material progress at least equal to that produced by the introduction of steam power in the early part of our century.

Dr. Siemens then considered the probable effect of such an engine upon our merchant navy, and gave interesting statistics from "Lloyd's Register of Shipping." He also touched upon the hydrographic department of the navy, and the subject of tidal action :—

The application of iron and steel in naval construction rendered the use of the compass for some time illusory, but in 1839 Sir George Airy showed how the errors of the compass, due to the influence experienced from the iron of the ship, may be perfectly corrected by magnets and soft iron placed in the neighbourhood of the binnacle, but the great size of the needles in the ordinary compasses rendered the correction of the quadrantal errors practically unattainable. In 1876 Sir William Thomson invented a compass with much smaller needles than those previously used, which allows Sir George Airy's principles to be applied completely. With this compass correctors can be arranged so that the needle shall point accurately in all directions, and these correctors can be adjusted at sea from time to time, so as to eliminate any error which may arise through change in the ship's magnetism or in the magnetism induced by the earth through change of the ship's position. By giving the compass card a long period of free oscillation, great steadiness is obtained when the ship is rolling.

Sir William Thomson has also enriched the art of navigation by the invention of two sounding machines; the one being devised for ascertaining great depths very accurately in less than one quarter the time formerly necessary, and the other for taking depths up to 130 fathoms without stopping the ship in its onward course. In both these instruments steel pianoforte wire is used instead of the hempen and silken lines formerly employed; in the latter machine the record of depth is obtained not by the quantity of wire run over its counter and brake wheel, but through the indications produced upon a simple pressure gauge, consisting of an inverted glass tube, whose internal surface is covered beforehand with a preparation of chromate of silver, rendered colourless by the sea-water up to the height to which it penetrates. The value of this instrument for guiding the navigator within what he calls "soundings" can hardly be exaggerated; with the sounding machine and a good chart he can generally make out his position correctly by a succession of three or four casts in a given direction at given intervals, and thus in foggy weather is made independent of astronomical observations and of the sight of lighthouses or the shore. By the proper use of this apparatus, such accidents as happened to the mail steamer *Mosel* not a fortnight ago would not be possible. As regards the value of the deep-sea instrument, I can speak from personal experience, as on one occasion it enabled those in charge of the cable s.s. *Faraday* to find the end of an Atlantic cable, which had parted in a gale of wind, with no other indication of the locality than a single sounding, giving a depth of 950 fathoms. To recover the cable a number of soundings in the supposed neighbourhood of the broken end were taken, the 950 fathom contour line was then traced upon a chart, and the vessel thereupon trailed its grapnel two miles to the eastward of this line, when it soon engaged the cable, twenty miles away from the point where dead reckoning had placed the ruptured end.

Whether or not it will ever be practicable to determine oceanic depths without a sounding line, by means of an instrument based upon gravimetric differences, remains to be seen. Hitherto the indications obtained by such an instrument have been encouraging, but its delicacy has been such as to unfit it for ordinary use on board a ship when rolling.

Here the lecturer dwelt upon the great engineering works of the present day, beginning with the Panama Canal, the gigantic undertaking recently commenced by M. de Lesseps. He also mentioned jointly with this project the ship railway of Captain Eads, which is intended to take the largest vessels, from sea to sea, over a railway across the Isthmus of Tehuantepec, a distance of ninety-five miles. A third enterprise with which the name of M. de Lesseps is connected was touched upon, that of flooding the Tunis-Algerian Chotts.

Dr. Siemens then dealt consecutively with the new Eddystone Lighthouse, the St. Gothard Tunnel, the English Channel Tunnel, the undermining of the estuaries of the Severn and Mersey for the purpose of connecting the railway systems on the two sides, and the spanning of the Frith of Forth by a bridge exceeding in grandeur anything as yet attempted by the engineer. He concluded this portion of his discourse by his remarks on the researches of Prof. Abel and Captain Noble on the action of explosives.

The extraordinary difference of condition before and after its ignition, of such matter as constitutes an explosive agent leads us up to a consideration of the aggregate state of matter under other circumstances. As early as 1776, Alexander Volta observed that the volume of glass was changed under the influence of electrification, by what he termed electrical pressure. Dr. Kerr, Govi, and others have followed up the same inquiry, which is at present continued chiefly by Dr. George Quincke, of Heidelberg, who finds that temperature, as well as chemical constitution of the dielectric under examination, exercises a determining influence upon the amount and character of the change of volume effected by electrification; that the change of volume may under certain circumstances be effected instantaneously as in flint glass, or only slowly as in crown glass, and that the elastic limit of both is diminished by electrification, whereas in the case of mica and of gutta-percha an increase of elasticity takes place.

Still greater strides are being made at the present time towards a clearer perception of the condition of matter when particles are left some liberty to obey individually the forces brought to bear upon them. By the discharge of high tension electricity through tubes containing highly rarefied gases (Geissler's tubes), phenomena of discharge were produced which were at once most striking and suggestive. The Sprengel pump afforded a means of pushing the exhaustion to limits which had formerly been scarcely reached by the imagination. At each step the condition of attenuated matter revealed varying properties when acted upon by electrical discharge and magnetic force. The radiometer of Crookes imported a new feature into these inquiries, which at the present time occupy the attention of leading physicists in all countries.

The means usually employed to produce electrical discharge in vacuum tubes was Ruhmkorff's coil; but Mr. Gassiot first succeeded in obtaining the phenomena by means of a galvanic battery of 3,000 Leclanché cells. Dr. De La Rue, in conjunction with his friend Dr. Hugo Müller, has gone far beyond his predecessors in the production of batteries of high potential. At his lecture "On the Phenomena of Electric Discharge," delivered at the Royal Institution in January, 1881, he applied a battery of his invention consisting of 14,400 cells (14,832 Volts), which gave a current of 0·054 Ampère, and produced a discharge at a distance of 0·71 inch between the terminals. During last year he increased the number of cells to 15,000 (15,450 Volts), and increased the current to 0·4 Ampère, or eight times that of the battery he used at the Royal Institution.

With the enormous potential and perfectly steady current at his disposal, Mr. De La Rue has been able to contribute many interesting facts to the science of electricity. He has shown, for example, that the beautiful phenomena of the stratified discharge in exhausted tubes are but a modification and a magnification of those of the electric arc at ordinary atmospheric pressure. Photography was used in his experiments to record the appearance of the discharge, so as to give a degree of precision otherwise unattainable in the comparison of the phenomena. He has shown that between two points the length of the spark, provided the insulation of the battery is efficacious, is as the square of the number of cells employed. Mr. De La Rue's experiments have proved that at all pressures the discharge in gases is not a current in the ordinary acceptation of the term, but is of the nature of a disruptive discharge. Even in an apparently perfectly steady discharge in a vacuum tube, when the strata as seen in a rapidly-revolving mirror are immovable, he has shown that the discharge is a pulsating one; but, of course, the period must be of a very high order.

At the Royal Institution, on the occasion of his lecture, Mr. De La Rue produced, in a very large vacuum tube, an imitation of the Aurora Borealis; and he has deduced from his experiments that the greatest brilliancy of Aurora displays must be in an altitude of from thirty-seven to thirty-eight miles—a conclusion of the highest interest, and in opposition to the extravagant estimate of 281 miles at which it had been previously put.

The President of the Royal Society has made the phenomena of electrical discharge his study for several years, and resorted in his important experiments to a special source of electric power. In a note addressed to me Dr. Spottiswoode describes the nature of his investigations much more clearly than I could venture to give them. He says: "It had long been my opinion that the dissymmetry shown in electrical discharges through rarefied gases must be an essential element of every disruptive discharge, and that the phenomena of stratification might be regarded as magnified images of features always present, but concealed under ordinary circumstances. It was with a view to the study of this question that the researches by Moulton and myself were undertaken. The method chiefly used consisted in introducing into the circuit intermittence of a particular kind, whereby one luminous discharge was rendered sensitive to the approach of a conductor outside the tube. The application of this method enabled us to produce artificially a variety of phenomena, including that of stratification. We were thus led to a series of conclusions relating to the mechanism of the discharge, among which the following may be mentioned:—

"1. That a stria, with its attendant dark space, forms a physical unit of a striated discharge; that a striated column is an aggregate of such units formed by means of a step-by-step process, and that the negative glow is merely a localised stria, modified by local circumstances.

"2. That the origin of the luminous column is to be sought for at its negative end; that the luminosity is an expression of a demp- -

for negative electricity, and that the dark spaces are those regions where the negative terminal, whether metallic or gaseous, is capable of exerting sufficient influence to prevent such demand.

"3. That the time occupied by electricity of either name in traversing a tube is greater than that occupied in traversing an equal length of wire, but less than that occupied by molecular streams (Crookes' radiations) in traversing the tubes. Also that, especially in high vacua, the discharge from the negative terminal exhibits a durational character not found at the positive.

"4. That the brilliancy of the light with so little heat may be due in part to brevity in the duration of the discharge; and that for action so rapid as that of individual discharges, the mobility of the medium may count as nothing; and that for these infinitesimal periods of time gas may itself be as rigid and as brittle as glass.

"5. That striæ are not merely loci in which electrical is converted into luminous energy, but are actual aggregations of matter.

"This last conclusion was based mainly upon experiments made with an induction coil excited in a new way, viz., directly by an alternating machine, without the intervention of a commutator or condenser. This mode of excitement promises to be one of great importance in spectroscopic work, as well as in the study of the discharge in a magnetic field, partly on account of the simplification which it permits in the construction of induction coils, but mainly on account of the very great increase of strength in the secondary currents to which it gives rise."

These investigations assume additional importance when we view them in connection with solar—I may even say steller—physics, for evidence is augmenting in favour of the view that interstellar space is not empty, but is filled with highly attenuated matter of a nature such as may be put into our vacuum tubes. Nor can the matter occupying stellar space be said any longer to be beyond our reach for chemical and physical test. The spectroscope has already thrown a flood of light upon the chemical constitution and physical condition of the sun, the stars, the comets, and the far distant nebulæ, which have yielded spectroscopic photographs under the skilful management of Dr. Huggins, and Dr. Draper of New York. Armed with greatly improved apparatus the physical astronomer has been able to reap a rich harvest of scientific information during the short periods of the last two solar eclipses; that of 1879, visible in America, and that of May last, observed in Egypt by Lockyer, Schuster, and by Continental observers of high standing. The result of this last eclipse exhibition has been summed up as follows: "Different temperature levels have been discovered in the solar atmosphere; the constitution of the corona has now the possibility of being determined, and it is proved to shine with its own light. A suspicion has been aroused once more as to the existence of a lunar atmosphere, and the position of an important line has been discovered. Hydrocarbons do not exist close to the sun, but may in space between us and it."

To me personally these reported results possess peculiar interest, for in March last I ventured to bring before the Royal Society a speculation regarding the conservation of solar energy, which was based upon the three following postulates, viz.:—

1. That aqueous vapour and carbon compounds are present in stellar or interplanetary space.

2. That these gaseous compounds are capable of being dissociated by radiant solar energy while in a state of extreme attenuation.

3. That the effect of solar rotation is to draw in dissociated vapours upon the polar surfaces, and to eject them after combustion has taken place back into space equatorially.

It is therefore a matter of peculiar gratification to me that the results of observation here recorded give considerable support to that speculation. The luminous equatorial extensions of the sun which the American observations revealed in such a striking manner (with which I was not acquainted when writing my paper) were absent in Egypt; but the outflowing equatorial streams I suppose to exist could only be rendered visible by reflected sunlight, when mixed with dust produced by exceptional solar disturbances or by electric discharge; and the occasional appearance of such luminous extensions would serve only to disprove the hypothesis entertained by some, that they are divided planetary matter, in which case their appearance should be permanent. Prof. Langley, of Pittsburg, has shown by means of his Bolometer, that the solar actinic rays are absorbed chiefly in the solar instead of in the terrestrial atmosphere, and Captain Abney has found by his new photometric method that absorption due to hydro-carbons takes place somewhere between the solar and terrestrial atmosphere; in order to test this interesting result still further, he has lately taken his apparatus to the top of the Riffel with a view of diminishing the amount of terrestrial atmospheric air between it and the sun, and intends to bring a paper on this subject before Section A. Stellar space filled with such matter as hydro-carbon and aqueous vapour would establish a material continuity between the sun and his planets, and between the innumerable solar systems of which the universe is composed. If chemical action and reaction can further be admitted, we may be able to trace certain conditions of thermal dependence and maintenance, in which we may recognise principles of high perfection, applicable also to comparatively humble purposes of human life.

We shall thus find that in the great workshop of nature there are no lines of demarcation to be drawn between the most exalted speculation and commonplace practice, and that all knowledge must lead up to one great result, that of an intelligent recognition of the Creator through His works. So then, we members of the British Association, and fellow-workers in every branch of science, may exhort one another in the words of the American bard who has so lately departed from amongst us:—

> Let us then be up and doing,
> With a heart for any fate;
> Still achieving, still pursuing,
> Learn to labour and to wait.

CALLENDER'S INSULATING MATERIAL.

SOME two months since we paid a visit to the Bitumen Works of Callender's Company, for the purpose of inspecting the manufacture of a new insulating compound prepared from crude bitumen. We were then favourably impressed with its adaptability for the above purpose. Upon the invitation of the Messrs. Callender we have had an opportunity during the last week of making a series of tests on several sections of vulcanised bitumen core, amounting altogether to some four miles.

The electromotive force of the battery we employed for this purpose was 300 volts, and ten minutes' readings were taken with each current on the lengths submitted to us. The size of the core was No. 18 copper, covered to No. 7 B. W. G.

As we shall shortly have occasion to take further tests, we do not purpose publishing the figures we obtained at present, and shall therefore content ourselves with stating that the results were highly satisfactory, and that the good opinion we had already entertained of this substitute for gutta-percha and india-rubber was more than upheld.

Mr. Callender's invention consists in the use of bitumen, combined with other hydro-carbons, or their equivalents, so as to produce a compound material. The natural deposit of bitumen is obtained from Trinidad, and is refined in the usual way. It is combined with oil residue, obtained by subjecting vegetable or other oils to distillation for such a time and in such a manner as to leave the residues in an elastic condition. In some cases Mr. Callender employs with these materials ozokerit, paraffin, or other wax, but this is not always essential.

The compound is then vulcanised, and it is then found to be an efficient substitute for either india-rubber or gutta-percha. The ingredients used are, of course, comparatively inexpensive, and the result is that the compound material can be manufactured and applied at a price considerably less than either of the former insulators. This method of covering wires being of quite recent date, we cannot give any particulars as to the lasting capabilities of the material, but being a mineral substance, and not vegetable, it would appear that it should be practically imperishable. We have no object in recommending Mr. Callender's system other than in the interests of electrical industries, and we have therefore no hesitation in saying that we believe Mr. Callender's invention is the beginning of great advances in cheapening our present insulated conductors. We shall note carefully the results of the tests of this material from time to time, as improved manufacture brings out more prominently the advantages promised by the use of the compound. At the present moment we can safely say that the subject on which we have made these remarks is one eminently worthy of the consideration of electricians; for whatever class of work they may be engaged in, they must all feel the want of reliable means of insulating wires otherwise than by the use of the two best known and most expensive materials.

THE EDISON ELECTRIC LIGHT AT THE GENERAL POST-OFFICE.

THE Edison Electric Light Company has completed an important installation at the General Post-office.

The officials at the Post-office have for some time been desirous of lighting the operating rooms in some satisfactory manner by the electric light. In the Press room, at the top of the buildings in St. Martin's-le-Gran[illegible] there are engaged some 1,200 operators. A consider[illegible] portion of these are engaged on night duty, and it [illegible] portant that this room should be well illuminated. [illegible] from the vitiation of the air by gas, it is obviou[illegible] health of the operatives and their capability f[illegible] be increased by some system of illuminatio[illegible] light without unnecessarily heating the apar[illegible] "systems" of electric light have been tried. [illegible] objection to most of these, apart from fail[illegible]

has been that the space of the Post-office is far too valuable to spare for dynamos and engines and boilers. Hence the problem remained unsolved.

It has now however received its solution at the hands of the Edison Electric Light Company. As is well known, the fundamental principle of the Edison system is the supply of electricity from a central station. For five months, without intermission, the Holborn Viaduct has been so supplied from the station at No. 57, Holborn Viaduct.

The shops, streets, hotels, and church, have received without fail the current necessary to supply them with light. On being applied to by the Post-office authorities to extend this supply system, the Edison Company complied with the request by laying down a cable along Newgate Street. The distance from the dynamo-room to the Press department in the Post-office is 1,950 ft. A cable composed of eight No. 10 wires was laid down in a creosoted teak trough under the pavement. Starting from the extremity of the electric mains previously laid down on the Viaduct subway, the cable extends for 1,014 ft. to the entrances to the Post-office. It was important to secure a sufficient insulation. This was achieved by overlaying the cable with insulated tape, and then laying it in grooves in the trough on bearers of insulite, placed one foot apart. The trough was then sealed up with the usual insulation compound. At intervals five testing stations were established. The total copper resistance of the double length of cable is 0·024 ohms. On entering the building the cable runs up the wall in an iron pipe, and enters the operating room. One of the Edison electric meters registers the amount of electricity which passes in. In the operating room, 63 of the 16-candle Edison incandescent lights are placed. These are, at present, attached to the gas fixtures. Over each electric lamp is a porcelain shade to throw down the light on the operator's work. At each branch wire leading to the lamp is one of the "safety catch protectors," consisting of a lead wire of such gauge as to carry the normal amount of current for each lamp, but to fuse with any excess. The evil effects of an accidental cross in the wires are thus prevented.

The whole of this work has been carried out by the company's staff in about ten days.

On Monday night the lamps were lighted for the first time in the presence of the officials of the Post-office. On turning off the gas and switching on the current, the room was silently illuminated with a uniform light, steady, soft, and considerably exceeding in brilliancy the gas which it replaced. The contrast between the calm, cool illumination of that portion of the gallery lighted by the incandescent light and that portion which still suffered under gas illumination was very marked.

No one who witnessed the experiment of last Monday night could fail to be struck with the absurdity of the remark still occasionally heard that electric lighting is still in an "experimental stage." In this case we have more than sixty lights, giving a uniformly steady light, absolutely under control by switches on each lamp and on each circuit supplied on a meter from a station nearly one-third of a mile away. A few lights are also to be placed in another room in the building. Nothing could better have demonstrated than this installation the exact adaptability of the Edison incandescent light for night work requiring good illumination.

A SINE-RHEONOME.—By E. v. Fleischl.—A wooden ball of 4·5 centimetres diameter, covered with coils of thick wire, revolves within a hollow wooden ball of 6 centimetres in diameter, composed of two halves, and covered with many coils of fine wire (2 kilometres in length). By means of suitable connections a current is passed through the coil of the internal ball. In the coils of the outer ball, which are parallel to those of the inner, a current is induced by rotation of the inner on an axle parallel to the plane of the coils. The induced electromotive force varies as the sine of an equally increasing arc.—*Wiedemann's Beiblätter.*

APPLICATIONS OF ELECTRICITY TO THE TRANSMISSION OF FORCE IN THE FRENCH MINES.

THE transmission of force to a distance by means of electricity has been confined almost entirely up to the present to the domain of pure speculation or of laboratory experiments. While noting these researches, made by professional electricians, it is not uninteresting to describe the experiments of a more practical nature made by the engineers in certain French mines. We shall find in them very careful observations and information all the more useful because it is not based on fixed ideas or interested considerations, having for their object to show the superiority of a certain system over all others.

The most important application to which we wish to call the attention of our readers is that made at the mines of La Perronière by MM. Charousset and Bague. The results obtained were communicated by the experimentalists to the *Société de l'Industrie Minérale* at the last Congress held at Alais in December, 1881; the report of MM. Charousset and Bague was published in full in the bulletin of the society. We shall select from it the essential parts, leaving out certain definitions too elementary for our readers, and certain other parts which relate more to the working of mines than to electricity.

The transmission of force at the mines of La Perronière has for its object to dispense with the extraction by means of horses which, with the mode of working necessitated by the conditions of the mine, would have been too hard work. These conditions necessitated the placing of an inclined descent on the line of the greatest slope of the grant, and a windlass placed at the head of the descent.

The distance between the motor and the windlass, which is itself placed 555 metres below the soil, is 1,200 metres, made up as follows:—

	Metres.
From the motor to the head of the oaken shaft ..	25
The length of the shaft	390
A gallery almost straight	380
A false shaft	30
A rounded gallery	290
A false shaft	25
A gallery..	60
Total length	1,200

This long distance rendered the employment of steam impossible; the necessity of laying down and maintaining 1,200 metres of tubes of compressed air, through winding galleries and shafts, also excluded that agent; therefore recourse was had to electricity.

The complete installation comprises a horizontal steam engine, placed near the drawing-shaft, and working two Gramme machines (generators), which send the current to two similar machines (motors), which work a windlass placed at the head of the descent. This descent, which serves to draw up the coal-tubs, is really 110 metres long, following the slope, and has an inclination of 40 centimetres per metre.

Generating Machines.—The motor which works the generating machines has a single cylinder and variable expansion, on the Meyer system, and is furnished with a Buss governor. It makes 65 revolutions per minute. The flywheel of the engine works an intermediate shaft, making 195 revolutions, which in its turn actuates a second intermediate shaft, performing 325 revolutions. This second shaft bears pulleys, which act directly upon the Gramme machine by friction; and for this purpose the extremities of the axles of the machines are furnished with rollers of compressed paper, and turning at 1,300 revolutions.

The type of Gramme machine employed in the mines of La Perronière is that called *octagonal*, with four poles and four collecting brushes; the corresponding poles are placed opposite to each other, and the ring changes in polarity four times in each revolution.

Receiving machines and windlass.—The receiving machines disposed inside the mine, bear, like those outside, two friction rollers of compressed paper. They are placed symmetrically in relation to the transmitters, and oscillate round a horizontal axle which serves them as a support. This frictional motion is utilised for the starting and the stopping of the windlass. The oscillation of the

Gramme machines in one direction brings the friction rollers into contact with the pulleys which are connected with the windlass by means of straps, and effect the starting. The oscillation in the contrary direction draws back the friction rollers and stops the windlass.

The slackening of speed at the commencement is effected by allowing the rollers to rub against the pulleys. In order that these operations may be performed regularly, independently of the degree of skill of the workman, the regulation of the oscillation of the machines is effected by means of a system of jointed levers and a screw worked by a fly-wheel. The degree of contact which must not be exceeded is determined by a second screw which arrests the movement of the former one. These very clever arrangements allow of the slackening of speed at the starting and arrival of the coal tubs at the head of the descent.

The Gramme machines always turn in the same direction owing to the arrangement of the brushes; changes of direction are effected by a cog and two conical wooden pinions, gearing with the same bronze wheel; this change is always made when the machines are at rest and out of gear. The motors turn at a speed varying from 6-10ths to 9-10ths of the speed of the generators, according to whether they are geared or turning freely.

The windlass comprises a cylinder 1·50 metres in diameter, on which are coiled two cables, 15 millimetres in diameter. A brake acts upon this cylinder so as to stop it when the Gramme machines are out of gear. The mechanic being above the machines can see the attaching of the coal-tubs, and also their descent; and besides, a screw with index indicates to him at any moment their exact position.

Near the workman at the windlass are two commutators, which are never to be used for the normal working; this workman communicates with the one outside when he wishes to stop the machine, or send an order to him by means of a telephonic apparatus, known as M. Locht-Labye's *pantéléphone*, an apparatus of great simplicity, and one which, when properly regulated, is not likely to get out of order.

Conductors.—The generating machines are connected with the motors by four insulated conductors; they form two completely independent transmissions, each generator having a connecting wire and a return wire for feeding the corresponding motor.

The insulation of the conductors was in principle the cause of certain difficulties now overcome; they had to be changed three times. They consist now of a strand of sixteen copper wires of 11-10 millimetres covered, first, with two layers of paraffined cotton; secondly, with a layer of gutta-percha 5 millimetres thick; thirdly, with two layers of cloth coated over with Chatterton's composition; and, fourthly, with a stout covering of tarred cotton.

The cable thus supplied by the manufacturer was covered again at the mine with a very adhesive and at the same time highly insulating material composed thus:—

Norwegian tar	57 parts.
Resin	38 ,,
Suet	5 ,,

This coating is laid on in order to preserve the layer of cotton from damp and hot gases. The cable costs 3 francs per metre.

In the shafts and galleries these cables are laid at a distance of at least 20 centimetres from each other. In the galleries they are supported on grooved planks extending from one beam to another of the gallery. If it is necessary to examine or repair them, it is sufficient to remove a few of the planks. The cables then being insufficiently supported fall to the floor of the gallery.

The most highly insulated cables are only placed in the damp parts, about 450 metres, the remaining 750 consisting of a cheaper kind of cable, at only 1·25 francs the metre. The insulation of these cables consists of a layer of paraffined cotton, covered with two envelopes of cloth coated with Chatterton's composition, the whole being protected by a layer of cloth coated with india-rubber.

Passage of the current.—We have seen that in the octagonal machine the collector has four brushes instead of two, as in the ordinary machines. These collectors can be grouped into two distinct pairs, and the current considered as being furnished by two distinct rings. These two rings are grouped *in quantity;* the current supplied by each passes through half the inductors, and the extremities of the wire are attached to the terminals of the generating machines, like two distinct machines grouped in quantity. The corresponding motor is mounted in the same manner; the whole of the electrical circuit is therefore identical with that of two similar dynamo-electric machines also joined up *in quantity.*

The four Gramme machines also form two distinct groups, each having a generator and a motor. Thus each group can be made to work separately, or the two groups together, according to the work to be performed.

Practical results.—MM. Charousset and Bague have made several very interesting experiments relative to the amount of work effected, the speed of the machines, the losses, &c. These experiments have brought forward some curious, almost unknown facts, at which we will take a rapid glance. In the first place they observed what has been thought for a long time, that when the speed of the motor increases the intensity diminishes, and that the intensity increases when the work effected increases. Unfortunately up to the present the experimentalists have only had simple galvanoscopes at their disposal, in which the function which connects the intensity with the angle of deviation is unknown. It was therefore impossible for them to determine the electrical conditions of the working of the transmission. Nevertheless, it is interesting to note the mechanical results. The experimentalists studied first the influence of the charge on the speed of the motors by imparting to the generators a constant speed of 1,280 revolutions, the conductors being in good condition as to insulation. Five series of experiments gave on an average the following results:—

Generators.	Motors.	Charge.
1,280	975	Windlass turning alone.
1,280	880	400 kilogrammes.
1,280	830	800 ,,
1,280	810	1,200 ,,
1,280	780	1,600 ,,

Sometimes a phenomenon was produced, somewhat curious at first sight, but easily explained. The motors, which are identical with the generators as to length and thickness of wires, &c., can, under certain conditions, acquire a speed greater than that of the generators. This fact may be attributed to several causes. The first has to do with the position of the brushes, adjusted with more or less nicety to the relative speeds of the two machines, and to the currents supplied by them; the second relates to bad insulation of the wires; the third to a contact between the spirals of the inductors of the motor, which MM. Charousset and Bague term a shortening of the electro-magnets, the effect of which is to weaken the magnetic field of the motor, and consequently to force it to turn at a greater speed in order to develop the same counter-electromotive force. This remark is of great importance, for it shows what an error can be made by asserting, as certain writers do, that the ratio of the speeds of two identical dynamo-electric machines coupled, one as generator, the other as motor, gives the theoretical *result* of the transmission. This is only true when there is no shortening of the electro-magnets, and when the brushes are well set, conditions difficult to realise in practice, especially with high tensions. Without the reservations we mention, we might find results greater than unity, which is simply absurd.

We will now give the *practical results* of the transmission according to whether the machines worked one, two, three or four coal-tubs on the descent of 110 metres, with an inclination of 40 centimetres per metre. We must here observe that if the figures relating to the results are not very high, it is because the experimentalists have included in the work expended all the passive resistances independent of the electrical transmission. In reality, the work *expended*, as given in the table, refers to the work indicated on the diagram of the steam engine, and the work produced is expressed in kilogrammes of coal drawn up the inclined plane. Thus in the charge of the electrical transmission are included the resistances attributable to the steam engine, the intermediate transmissions, the state of the road, the work expended on the windlass, the friction of the wheels of the coal-tubs on their axles, &c., &c.

These figures are, therefore, really the practical result under certain special conditions, and constitute a minimum which will be far exceeded in practice, when we only attribute to the electrical transmission the losses which legitimately belong to it.

Remarks.—The numbers in columns 1 and 2 are expressed in kilogrammetres. In order to reduce them to *chevaux vapeur*, they must be divided by 75.

EXPERIMENTS.	Work expended according to the diagram. 1.	Useful Work. 2.	Speed of Generator. 3.	Speed of Motor. 4.	Practical result. 5.
1. Steam engine working freely	312	0			
2. Engine with transmission ...	458	0			
3. Engine with generator, open circuit	518	0			
4. Engine with generator and motor turning freely	530	0			
5. Steam engine with windlass alone	610	0	1,280	975	
6. Steam engine with 1 coal-tub	1,050	128	1,280	880	12·2
7. ,, ,, 2 ,,	1,200	223	1,280	830	18·6
8. ,, ,, 3 ,,	1,370	317	1,280	810	23·1
9. ,, ,, 4 ,,	1,530	400	1,280	780	26·1

The above table shows that the engine with transmission absorbs 458 kilogrammetres per second. When we subtract this number from the total required for the engine when drawing four coal-tubs, the expenditure of work is only 1,072 kilogrammetres per second, and the practical result measured by the weight of coal raised is 37 per cent. It would be still higher and would amount to about 50 per cent. if the work effected were measured, not by the weight of coal raised, but directly on the axle of the motor.

Up to the present only one generator and one motor have been used; the steam engine employed is much too powerful for the result actually obtained, but soon the two generators will be used; the second motor will be adapted to another windlass acting on another descent.

Remarks on the cables.—The cables not covered with gutta-percha answer the purpose very well in the galleries where the air is dry, but become deteriorated in damp places after a month's use. The workmen received shocks on touching them, or on touching the stones of the sides of the shaft in the neighbourhood of the conductors. The lead covered cables, the insulation of which was not sufficiently thick, also gave bad results. The lead melted in certain places, and the cloth coated with Chatterton's composition was burnt at the points where the lead had disappeared. The copper wires showed globules of melted metal. It is probable that derivations to earth were established between the two conductors of the machine. The cables covered with gutta-percha gave the best results, and since they have been employed there has been no hitch.

Summary.—MM. Charousset and Bague have concluded from their observations that electricity employed to transmit force to a distance will replace with advantage, as regards the results obtained, the cost of installation and especially of maintenance, compressed air and mechanical traction, especially in the following cases:—

I. When the mine is not too much impregnated with fire-damp.

II. When the distance between the motor and the receiver is great.

III. When the galleries destined to receive the medium of transmission cables, pipes, or chains, are winding, when only one series of galleries and false shafts meeting at right angles are at our disposal for transmission.

The experiments made at a distance of three kilometres showed that the result varies very little with the distance.

We must avoid dampness as far as possible, as we are free to take the longest path for the cable, and also vibrations which are injurious. When the transmission is effected by friction, pulleys turned perfectly true should be used, and finally the ratio of the speeds of the generators and motors should be maintained at about 0·6, whatever may be the effect to be produced. We see that the installation established at the mines of La Perronière furnishes us with very valuable *practical* information on the installation of transmissions of motive force in mines.

In a future article we shall discuss what has been done at Montceau-les-Mines, and at Saint-Claude for applications of the same kind.

THE CITY AND GUILDS OF LONDON INSTITUTE TECHNOLOGICAL EXAMINATIONS.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Your correspondent "Fareham" seems to consider it an established fact that the "Cowper Street Student" is possessed only of an "examinational" knowledge of telegraphy. Such being the case, it may reassure him to know that the aforesaid student is practically engaged in electrical testing, though not in the Postal service, and probably does as much testing in one day as his unfortunate friend does in a month.

I am, Sirs, faithfully yours,

THE STUDENT.

THE RIVAL TELEPHONE COMPANIES.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Your correspondent "Justice" has a little more of *law* than of *justice* in his composition. He lays down with airy authority that, "any transmitter, combining a diaphragm with a tension-regulator, be it Hunnings', Dolbear's, or Anders', is clearly an infringement." This is surely a little premature. How does "Justice" know that Anders' transmitter is such a combination? Has he ever seen one? Will he describe its parts? If he cannot—and I defy him to do so, because I know he has never seen one—he belies his pseudonym. Again, if his verdict were the voice of justice Reis's transmitter of 1861 would be an infringement of Edison's patent, because it undeniably combines a diaphragm with a tension-regulator. This would be truly "Justice's" justice, to declare that the invention of 1861 was an infringement of the patent of 1877. No doubt Edison is as angry as any one else that an obscure German should have stolen his ideas sixteen years beforehand. It is clearly an in-"Justice" to so great an inventor. But stay, was not the great inventor himself started on the quest by having a manuscript translation of a paper on Reis's Telephone put into his hands by the President of the Western Union Telegraph Company? Does not the great inventor himself say so in Prescott's "Speaking Telephone?" If so, where is the

INJUSTICE?

THE TELEPHONE.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Pardon me for expressing my great astonishment that you should (no doubt unwittingly) have even suggested in your remarks on "The Telephone Industry" to the too timorous, that the United Telephone Company think Edison's single claim covers any semi-conductor placed in between any two points of a telephonic circuit, especially when you have before you the full reports of the evidence and judgments in two suits brought by the United Telephone Company for infringements of Edison's and Bell's patents. The last surviving claim out of thirty in Edison's notorious much-disclaiming patent is in these words:

"In an instrument for transmitting electric impulses by sound the *combination* with a diaphragm or tympan of electric tension-regulators, substantially as hereinbefore described for varying the resistance in a closed circuit, substantially as set forth."

In the Edinburgh case Lord M'Laren used these words:—

"Edison's patent is not for a specific instrument, but for a combination;" and further on he said, "I suppose if Theiler dispensed with a diaphragm, he would be without

the patent, because the tension of the diaphragm is the material point;" to this the Lord Advocate, counsel for the United Telephone Company, replied, 'Yes.'"

Lord M'Laren further said, "Now, as Edison's patent is for a tension-regulator in combination with a diaphragm or tympanum, it follows that the interdict would not apply to the use of the respondent's carbon regulator without a tympanum," and being satisfied that the respondent's instrument involves the combination of a tension-regulator with a tympanum, the complainers (the United Telephone Company) are entitled to protection by interdict under Edison's patent."

In the case decided by Mr. Justice Fry, in May last, the learned Justice said: "The true meaning of the second claim in Edison's patent is the union of a tympan or diaphragm capable of vibrating under the sound-waves with an electric tension-regulator;" and further, "I have concluded that Edison described the essential requisite of his invention to be the combination of a vibrating diaphragm and a tension-regulator," and I have come to the conclusion that the Hunnings transmitter is the combination of a diaphragm vibrating with the voice with a tension-regulator, and therefore is an infringement of Edison's."

To these two decisions I will add that of Lord Cairns (L.R. 1, app. ca. 574) (L.R. 3, app. ca. 34): "If it is clear that the claim is for a combination, and nothing but a combination, there is no infringement unless the whole combination is used, and it is in that way immaterial whether any or which of the parts are used." Those who may believe that two added to two does not make four may also believe that Edison's claim is not limited to "a combination," and that it covers any semi-conductor placed in a telephonic circuit.

I may here add that the judgment of Lord Cairns applies in all its force to Bell's claims of "the combination of an electro-magnet or of a permanent magnet with a plate of iron or steel or other material capable of inductive action." It may not be amiss just now to give publicity to the following law: "Should a person injure the business of another by pretending that that other's manufacture is an infringement of a valid patent when such is not the case, the aggrieved party can obtain costs and damages, and obtain a perpetual injunction restraining him from further intimidation on pain of fine and imprisonment."

I beg however to dissent from your opinion, that this is "an unsatisfactory state of affairs," in regard to the unique claim of Edison's patent; on the contrary, the present state of affairs under the decisions above referred to is perfectly satisfactory, and the use of carbon in tension-regulators *without* a diaphragm is open to all the people of the United Kingdom, as is also the case in a telephone of a magnet in combination with a diaphragm, disc or plate of any material *not* capable of inductive action.

In my transmitters I use various forms of carbon tension-regulators without a diaphragm or tympan, or a colourable imitation thereof, and in my telephones I use various forms of permanent magnets and of electro-magnets without a plate, or disc, or diaphragm of any material capable of inductive action or any colourable imitation thereof, and I challenge any person to gainsay the rights I claim to use those devices, and at the same time I caution all persons against pretending that my inventions, viz., patent 4905, November 9, 1881, and 2259, May 13, 1882 (under which I have manufactured and have sold instruments), are infringements of any valid patent.

If the owner of any valid patent believes that my instruments are infringements of his patents, let him take legal notice forthwith of my avowal or beware of what the law terms "laches."

Yours truly,

W. C. BARNEY.

53, Bernard Street, *August 20th*, 1882.

[Mr. Barney throws out a bold challenge here to the United Telephone Company to contest their exclusive right to carbon tension-regulators. Our correspondent, however, has apparently overlooked the fact that in our article we expressed ourselves as having different views on the matter in question to those promulgated by the United Telephone Company. We rather think that Mr. Barney has erroneously considered "inductive *action*" to be synonymous with "induction."—EDS. ELEC. REV.]

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—I herewith send to you a continuation of my report of patents for telephone receivers for 1880-1881.

List of British patents for telephone receivers in which a disc capable of inductive action is used in combination with a magnet:—

1880.

No.	Date.	Inventor.	Remarks.
158	January 14th	Crossly	
752	February 28th	Eaton	
1,738	April 20th	Russell	
2,610	June 26th	Gower	
3,473	August 27th	St. George	
3,885	September 25th	A. G. Bell	
4,981	November 30th	Randall	

Telephones without a disc capable of inductive action:—

No.	Date.	Inventor.	Remarks.
2,419	(?) June 15th	Lockwood & Bartlett	

1881.

Telephones with a disc, capable of inductive action:—

No.	Date.	Inventor.	Remarks.
93	January 8th	Herz	
286	January 22nd	Konigslieb	
542	February 8th	Sax	
1,885	May 2nd	Main	
5,385	December 9th	Foster	
5,430	December 12th	Rose	
5,431	December 12th	Rose	

Telephones without a disc capable of inductive action:—

No.	Date.	Inventor.	Remarks.
1,395	March 29th	Dolbear	No magnet
4,905	November 9th	Barney	
5,028	November 16th	Theiler	

1882.

No.	Date.	Inventor.	Remarks.
2,259	May 13th	Barney	

All the patents for transmitters from December 9th, 1876, to January 13th, 1882, have the combination of a diaphragm, with a tension-regulator, except No. 4,905, November 9th, 1881, Barney; and this consists of a number of carbon pencils, the ends of which rest loosely in carbon blocks, which form two sides of a frame, the other two sides being of any non-conducting material, without any back or front.

Yours truly,

COMMON SENSE.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—I am delighted that Count du Moncel is beginning to see daylight dawn upon Reis's telephone. He admits that Reis's receiver will receive when the transmitter is good, he admits too that Reis's transmitter will transmit when the receiver is good. The only difficulty now remaining is the difficulty of admitting that a receiver, which will receive, and a transmitter which will transmit, will work together as receiver and transmitter. It is simply a question of fact, Reis and his contemporaries did succeed in transmitting intelligible speech; though they tell us honestly that the vowels were often bad. I have had no great difficulty in succeeding myself, and with reasonable precautions, such as keeping the membrane dry, not shouting too loud, &c., the experiment is simple.

Count du Moncel thinks it "very extraordinary" that such an important discovery did not obtain more publicity. That the lack of greater publicity is "very extraordinary" may be true, but that does not disprove the facts. It only proves that either the fact was so very extraordinary that men did not believe it, ... or else that they did not read German.

But I must be permitted emphatically to differ from Count du Moncel when he charges me with having "not kept to the subject," when I made some remarks on the question of the use of semi-conductors. I quite agree that the question of semi-conductivity has nothing to do with the question. But it was Count du Moncel himself who introduced that very irrelevant point into his preceding letter.

As Count du Moncel continues to reiterate that a loose contact between two good metallic conductors will not produce telephonic effects as well as a loose contact between two imperfect conductors, permit me to reiterate, on my part, what Count de Moncel has neither disproved nor denied, and which he must both deny *and* disprove experi-

mentally before his arguments can have any weight, viz., that if you take an ordinary Blake transmitter, and in place of the bad-conducting button of carbon, put in a bright polished button of the very best conducting metal, silver, the transmitter will transmit speech just as well as before.

I particularly invite Count du Moncel to do me the favour first to *deny*, secondly to *disprove* this result.

Yours faithfully,
SILVANUS P. THOMPSON.

ELECTRIC LIGHTING TENDERS.

To the Editors of THE ELECTRICAL REVIEW.

DEAR SIRS,—In the report of the statutory meeting of the Metropolitan Brush Electric Light and Power Company, Limited, published in your issue of 19th instant, the following question was asked by a Mr. Price: "The Camberwell Streets Committee asked for tenders to light with electricity the streets in their district; only one tender was sent in. Was it theirs? And if not, why did they not tender?" To this question Mr. Hammond replied: "The one tender sent in to the Camberwell vestry was that sent by this company, the Brush." And he further stated, "he Mr. Hammond would be the last man to dodge the question asked," &c., &c., &c. Will you allow me most emphatically to contradict the above? The only tender sent in was sent for the Pilsen-Joel and General Electric Light Company, Limited. The statement was made to me when, as the representative of the company, I handed in the Pilson Company's tender; and further, the Pilsen-Joel and General Electric Light Company's tender was the only one sent in for another metropolitan district, viz., West Ham. And there are many other cases in which the Pilsen Company is the only company in the field.

Yours respectfully,
JAMES BEATTIE.

Representing the Pilsen-Joel and General Electric Light Company, Limited.

THE BRITISH ASSOCIATION.

BY OUR SPECIAL REPORTER.

SOUTHAMPTON, Wednesday Evening.

THIS morning the 52nd annual meeting of the great scientific congress of the year was opened here amid much enthusiasm. Thirty-six years have elapsed since Southampton was thus honoured, the last occasion being in 1846, when Sir Roderick Murchison presided. Both Southampton and science have advanced, in the generation that has elapsed since that date, by "leaps and bounds," and the very elaborate arrangements for the conduct of the 1882 meeting of the Association may be regarded as the tribute of modern commerce to the scientific knowledge which has so much contributed to its advance. The reception room at the Victoria Hall, which forms the centre of the operations of the Association, has been specially provided with telegraphic, telephonic, and post-office conveniences, such as had not entered into the minds of the scientists of 1846 even to conceive, and the whole town is *en fête* with streamers and bunting, while the arrangements and invitations for visits of pleasure are exceptionally complete and numerous. The congress opens its annual "palaver" under the most favourable auspices, and the 1,070 members and associates who have up to the moment of writing announced their presence may look forward to a pleasant as well as an interesting and instructive *séance*. To-day was mostly devoted to preliminaries. The Council of the Association met at 10 a.m. in the Victoria Rooms, the General Committee followed at 1 p.m. to consider and adopt the council's report, a meeting of Sectional Committees took place at two o'clock, and the skating rink was crowded to the door in the evening to hear the formal beginning of Association work in the shape of the inaugural address by Dr. Siemens, the president for the year. The council, in its report, after noting the corresponding members elected during the year, refers to the loss sustained by the untimely death of Prof. F. M. Balfour, F.R.S., the late general secretary. They request authority for taking steps to ascertain the feeling of foreign scientific associations as to the advisability of holding an international scientific congress, and announced that they have made a contribution of £100 towards the expenses of an expedition for the exploration of the snowy mountain range of Eastern Equatorial Africa. They further recommend the re-election of certain members who retire by rotation. The report was generally approved of by the general committee after a somewhat languid discussion on some minor details. In the evening the Southampton streets began to fill with an unwonted bustle, and amidst a downpour of rain a converging crowd of scientists and local notables, with a large proportion of ladies, surged towards the skating rink, where Dr. Siemens was to take the sceptre from the hand of Sir John Lubbock. The rink was gaily decorated, and in front of the platform a large silk banner waved, on which was embroidered the armorial bearings of the president elect, with his motto, "Aus Eigener Kraft," prominently displayed. In resigning his chair Sir John made felicitous and graceful reference to Dr. Siemens being of foreign birth, and distinctly scored one when he remarked that he was himself the best illustration of the *energy* upon which he believed he was to speak that evening. Dr. Siemens was received with enthusiastic cheers on rising to read his address, and his slow and deliberate utterance was intently listened to during the hour and three quarters that it lasted. At the close of the address a vote of thanks was passed by acclamation on the motion of W. H. Davis, Esq., Mayor of Southampton, seconded by Dr. Spottiswoode, president of the Royal Society. The platform list included the following names amongst many others: Sir John Lubbock; Sir Richard Temple; Sir Frederic Bramwell; Sir William Thomson; Prof. Abel; Prof. A. W. Williamson, Ph.D., F.R.S.; Prof. De Chaumont, M.D., F.R.S.; Mr. Hawksley, C.E.; Mr. John Fowler, C.E.; Capt. Douglas Galton; M. Du Bois-Raymond; Dr. Werner Siemens; Dr. Spottiswoode (President of the Royal Society); M. P. de Tchihatchef, of Florence; Mr. W. H. Barlow, C.E., F.R.S.; Prof. W. F. Barrett, F.R.S.E.; Mr. R. Etheridge, F.R.S.; and Sir Joseph Hooker, F.R.S.

The programme during the session is in outline as follows:—

THURSDAY.—The Sections meet at 11 a.m. In the afternoon the Mayor and Mayoress give a reception at the Municipal Offices. At 8 p.m. the Local Committee give a soirée at the Hartley Institution, which will be lighted by the electric light, supplied by the Edison Company.

FRIDAY.—Sections at 11 a.m. At 3 p.m. the Committee of Recommendations will meet at the Reception Room. In the afternoon the Mayor and Mayoress give a reception at the Municipal Offices; and in the evening, at 8.30, Sir William Thomson, Professor of Natural Philosophy at the University of Glasgow, will deliver a discourse on "The Tides" at the Skating Rink.

SATURDAY.—The Sections meet at 11 a.m. The afternoon will be devoted to excursions—(1) to Alum Bay and the Needles; (2) the New Forest; (3) Netley Abbey and Netley Hospital, where Surgeon-General Holloway, C.B., and the officers of the Army Medical Department will give a garden party to about 300 at the officers' mess; (4) Romsey Abbey and Broadlands Park, where the members will be received by Lord and Lady Mount Temple at tea; and (5) Winchester and St. Cross. At 7 p.m. a popular scientific lecture to the operative classes on "Unwritten History, and how to read it," is to be given at the Skating Rink by Mr. John Evans, D.C.L., F.R.S. The arrangements for this lecture have been carried out by a local working men's committee.

SUNDAY.—At 10.45 the Bishop of Truro will preach at St. Mary's Church (Broad), the members and associates, with the Mayor and Corporation, attending. The same morning, at 11, the Rev. C. Pritchard, Savillian Professor of Astronomy at Oxford University, will preach at All Saints' Church (Evangelical).

MONDAY.—Sections at 11 a.m. At 3 p.m. the officers for 1883 will be elected and the place of meeting in 1884 fixed. In the afternoon Canon Basil and Mrs. Wilberforce give a garden party in the Deanery grounds. At 6.30 for 7 o'clock a special Provincial Grand Lodge of Hants and Isle of Wight Freemasons will be held at the Masonic Hall in Albion Place, opposite All Saints' Church, in order to welcome Freemasons visiting Southampton. At 8.30 p.m. in the Skating Rink, Mr. H. N. Mosely, M.A., F.R.S., Linacre Professor of Human and Comparative Anatomy at Oxford University, will deliver a discourse on "Pelagic Life."

TUESDAY.—Sections at 11 a.m. At 3 p.m. meeting of Committee of Recommendations; at 8 p.m. a soirée at the Hartley Institution, at the invitation of the Mayor and some members of the Corporation.

WEDNESDAY.—At 10 a.m. meeting of Committee of Recommendations; at 1 p.m. the General Committee will meet at the Skating Rink to receive the report of this Committee of Recommendations; and at half-past 2 in the afternoon the concluding meeting of the Association takes place.

THURSDAY will be devoted to excursions—(1) to Salisbury and Stonehenge, or Wilton; (2) Ryde, Brading (for the Roman Villa), or Whitecliff; and (3) two marine excursions, including Portsmouth.

The Queen has assented to an application for the members of the Association to visit Osborne after her departure for Scotland, which will probably be about Friday next; and the Union Steamship Company will issue invitations for a whole day marine excursion on their steamer *Pretoria*.

By telegram we learn that on Thursday the business of the Association commenced in earnest, and the section of Biology in particular has not proceeded further than the presidential address. In two of the departments a respectable amount of work, as represented by the papers read, has been got over up to the hour at which sectional meetings stood adjourned. The number of tickets issued at 3 p.m. was 1,150, which it is understood contrasts somewhat unfavourably with the issues of recent years, but the attendance of the various departments has been fully up to the usual average.

The numerical honours of the day may be said to have fallen to the mechanical science section in which Mr. John Fowler delivered his presidential address to a crowded house.

Mr. Fowler reviewed the progress of engineering science in a graphic and humorous fashion, the audience being particularly tickled by the contrast which he drew between the performance of the engines at the opening of the Liverpool and Manchester railway in 1830, when thirty-three miles were got over in five hours with the aid supplied by passengers walking up all the inclines; and the mile a minute speed to which the present generation is so accustomed.

Dr. Siemens, in proposing the vote of thanks, rather complained that the President had omitted to discuss the progress of applied electricity, but the address may be looked at as one of the most comprehensive of the day.

Mr. Baker followed with a most exhaustive account of the Forth Bridge, which manifestly interested his auditors to no common degree.

Lord Rayleigh led off the Mathematical Section by a suggestive little address respecting the qualifications required for, and the dangers to be avoided in, scientific research. The large portion of the audience who remained to hear Mr. Darwin's paper on Gravitation Disturbance were well rewarded both by the paper itself and by Sir William Thomson's interesting criticism. The succeeding subjects covered a wide field, from the recent Eclipse and Spectrum Analysis to the Velocity of Light and "Some Matters concerning the Sun." The Chemical Section, after Prof. Liveing's address, was poorly attended, and the same may be said of the Geological and Economic departments, though the names of Leone Levi, Mr. Abel, and Mr. Etheridge guaranteed the quality of the fare presented. To-morrow may be regarded as the steadiest working day that the Association will have at its disposal. Saturday's and next week's holidays must distract the attention of even *savants*. This afternoon has brought us a large accession of names of note, including Dr. Gladstone, Profs. Adams, Cayley, Milne, Stewart, and Schuster, Sir Henry Bessemer, Mr. Glaisher, and others. An element of discomfort is the threatening weather, but it is hoped that the success of the gathering will not be thereby seriously disturbed.

NOTES.

ERRATUM.—Page 131, column 1. Maxim light—read "Edinburgh" for "Glasgow."

DANGER FROM ELECTRIC LIGHTING.—We are informed upon good authority that the two deaths occurring recently in the Tuileries were occasioned by the current from an alternating current Siemens' dynamo-electric machine.

Le Ménestrel states that the electric light nearly caused a conflagration at the Paris Opera last week during a performance. The current being too strong, the wires became red hot, and their gutta-percha covering being quickly destroyed, the adjacent inflammable material began to smoulder, and the services of the firemen had to be called ition.

ELECTRIC LIGHT INSTALLATIONS.—We are glad to observe that signs of improvement are visible in the erection of electric light apparatus. Mr. Dickson, in addressing those present at the first general meeting of the Brush Electric Light and Power Company of Scotland, said, in reference to the lighting of Waverley Station, "The North British Company are quite aware of whom they are dealing with. They only had 16 arc lights last year, and they have now given us an order for double that number. We are carrying out that order with an efficient staff and proper instruments, so that the sort of slipshod way in which it was done before will not recur in the management of your board of directors."

SECONDARY BATTERIES OR ACCUMULATORS.—The *New Haven Evening Register* of America in speaking of the "Sutton" secondary battery says: "This form of battery was improved upon by Charles E. Buell of this city, who employed common lead shot, coated with mercury, and placed in a porous cup. He put this cup in a glass cell and surrounded it with a coil of copper-wire cloth, which served as the positive electrode. The employment of shot and wire cloth furnished the greatest surface in a given weight and constitutes a form most easily made. Mr. Buell verifies the published statement of Mr. Sutton that a cell four inches high and four inches in diameter will keep a No. 28 iron wire at red heat for two hours; that it is more constant, and does not polarise during discharge, as does the Faure battery. It weighs very much less, occupies less space, and costs less than the Faure battery of like force, and is untrammelled by patent rights."

THE ELECTRIC LIGHT IN HOLBORN.—Information has been sent to us that the Pilsen-Joel, and General Electric Light Company has secured the following orders:—At the Inns of Court Clothing Company and the Bon Marché Clothing Company, respectively, four Pilsen arc lamps, giving a stated luminosity of 2,000 candles each. These will be worked from the station in Whetstone Park to which we have already referred.

THE PILSEN-JOEL AND GENERAL ELECTRIC LIGHT COMPANY.—We believe that the statutory meeting of this company will shortly be held, and it will be interesting to the shareholders to know what progress has been made since its formation. We were under the impression that the system of lamps and machines worked by this company would give it a leading position in the electric lighting world, and we still hold the same opinion, but for reasons we cannot fathom the operations of the Pilsen-Joel Company do not appear to be so energetic as promised in the beginning. This, however, it is to be hoped will soon be remedied, if the directors have any wish to meet the demands likely to be put upon their resources during the forthcoming winter. It is evident that the working arrangements of this company are not yet all that could be desired; in fact, it is but too apparent that there is considerable room for improvement. We would strongly urge upon the directors, in their own interests and in those of their shareholders, to give the subject their earnest and prompt attention. With their good system and business management the Pilsen-Joel Company should be second to none. Commercial ability solely has made one prominent company the enormous success it is.

NEW METHOD OF INSULATING ELECTRIC WIRES.—M. H. Geoffroy has just presented to the Academy of Sciences a process of insulating conducting wires, with the object of preventing all chances of fire, even when the wires are in contact with combustible materials. This process consists in covering the conducting wires with a coil of asbestos fibres and then placing them in a leaden tube as is generally done; the wire can be entirely volatilised without the spark communicating with the outer coverings, the lead not showing any signs of fusion. With a powerful current the volatilisation of the wire lasts the tenth part of a second; the copper being once burned the current is naturally interrupted. Besides, the electrical insulation is satisfactory.

TRANSMISSION OF ELECTRICITY FOR LIGHTING PURPOSES.—At the meeting of the Metropolitan (Brush) Electric Light Company, a full report of which appeared in the ELECTRICAL REVIEW of last week, Mr. Hammond said, in the course of his remarks, that the Charing Cross Railway Station was lighted from the Brush Company's station at Lambeth, *a thing which was only possible with the Brush system.* Mr. Hammond had evidently overlooked the lighting of Victoria (underground) Station by the Jablochkoff Company from their station on the Thames Embankment. He should also be aware that it is quite *possible* for the British Electric Light Company, Messrs. Siemens Brothers, the Pilsen-Joel, &c., Company, and others to extend their systems to long distances from a central station if they choose to construct their machines so as to give a dangerously high electromotive force. At the same meeting Mr. Wm. Ladd spoke in much the same strain as Mr. Hammond, and if his remarks could be looked upon as true, then the Brush machine is superior in every way to others.

THE ELECTRIC LIGHTING BILL.—The Board of Trade notify that the rules with respect to applications for licenses under the Electric Lighting Act of 1882 may be obtained from P. S. King, King Street, Westminster; Knight and Co., 90, Fleet Street, E.C.; Shaw and Sons, Fetter Lane, E.C.; Hadden, Best and Co., 227, Strand, W.C.; A. and C. Black, Edinburgh; and A. Thom and Co., Dublin.

THE LIGHTING OF THE MANCHESTER ROYAL EXCHANGE BY THE BRITISH ELECTRIC LIGHT COMPANY, LIMITED. (Extract from the *Manchester Courier*, Tuesday, August 22nd, 1882).—"It will be remembered that a short time ago the directors of the Manchester Royal Exchange decided to test the capability of the electric light in the illumination of the building, and last evening an experiment was made in the lighting by electricity of the interior of the structure with most satisfactory results. At the same time two lamps were brought into operation on each side of the portico in Cross Street, the effect being that they completely eclipsed what had been up to then considered the brilliant light of the recently introduced patent gas lamps in the adjoining part of Market Street."

SPREAD OF ELECTRIC LIGHTING.—At the last meeting of the Fulham District Board of Works the seal of the board was affixed to an agreement with the West Middlesex Electric Light Company empowering the company to lay wires enclosed in pipes under the footways throughout the parishes of Fulham and Hammersmith. The distance of the roads in the district is 39 miles, and the number of houses 29,000. It is proposed to erect at suitable points central stations upon a large scale within the two parishes for the purpose of generating the electricity. For street lighting Brockie's arc lamps will, at present, be fixed, and for shops and private houses the British incandescent lamp. The light is already being extensively sought after by many of the largest tradesmen in the district, who are desirous of using it. The Brush Midland Electric Light Company (Limited) have entered into a contract for the lighting of the town of Cleethorpe for the next three years. The Severn Tunnel Works, Monmouthshire, are also being lighted on the Brush system, and preparations are being made for extensive lighting at Bristol, Newport, and Cardiff during the coming winter. At St. Martin's-le-Grand the Edison incandescent system has been fitted up in the newsroom. The current is sent from the company's central station on Holborn Viaduct, a distance of about half-a-mile. At Southampton the theatre of the Hartley Institution is being illuminated by this company's system during the meetings of the British Association. At the forthcoming North East Coast Exhibition at Newcastle, the Gülcher, Hammond, and Pilsen-Joel Companies are to display their respective systems. In Scotland there is also evidence of advance. In a recent issue we said the North British Company had decided to extend the electric light at their Waverley Station, Edinburgh. We learn that the number of lamps is to be increased from sixteen to thirty-two and that the cost to the company shall not exceed what they have hitherto paid for gas; which, it may be added, was manufactured by themselves. Each lamp is of 2,000 candle-power, and its cost is put down at $2\frac{1}{2}$d. per hour. In addition to this undertaking, the Scottish Brush Electric Light and Power Company are making arrangements for the lighting of Portobello station and goods loading depôt (one of the busiest stations on the North British system) by electricity at gas rates. A number of other stations are mentioned, among them Dundee, Arbroath, and Inverness. Private firms throughout the country are making inquiries and inviting tenders.

In New York wires have been laid down in the streets by the Edison Company and everything is on the eve of completion, so that by the first week in September a very considerable portion may be wholly lighted up by electricity.

PATENTS FOR INCANDESCENT ELECTRIC LAMPS.—We have received information that the British Electric Light Company have recognised the fact of their infringement of the Edison patents for electric lighting by paying a substantial sum as royalty to the Edison Electric Light Company, Limited. We are advised that this infringement refers only to a feature in the construction of the lamp.

THE GOVERNMENT AND THE TELEPHONE COMPANIES.—We extract from the *Times* the following letter, in reply to one signed "Electrician," part of which we published last week:—

SIR,—Your correspondent "Electrician" states the case of the Telephone Companies' so-called "free competition" well, so far as he goes. But in your article in the *Times* of to-day you speak of "enforcing, in the interests of the Crown and the public, only such conditions as are necessary to protect the revenue and to insure to the Post Office the means of competing freely on its own account."

Note the words, "only such conditions." One of the conditions is that the companies to whom licenses are granted shall supply the same class of instrument used on their lines for use by the Post Office in the same district for which the licence is granted. The price of these telephones to be fixed by arbitration.

The only companies to a certain extent exempt from this obligation to supply telephones are the United and the National.

Another condition is that the telephone companies, before erecting any line, shall supply to the engineer of the Post Office a plan showing how that line will run; and if the engineer thinks that it will interfere either with the existing Post Office wires or with any route they intend to lay out in future, the consent is refused, after the telephone company has had all the trouble and expense of obtaining way-leaves, &c.

In addition to the royalty of £2 per subscriber, the Post Office charges private companies a royalty of about £1 a mile per subscriber for communication between one centre and another; and before granting permission to make the connection makes the telephone company gurantee a *minimum* of eight subscribers. Thus, between Leeds and Bradford, a distance of only nine or ten miles, the Telephone Company is charged £10 per subscriber.

Is this fair competition? the Post Office paying no royalties on instruments and no tax to Government.

Faithfully yours,
FAIR PLAY.

London, *August 17th.*

THE OTRANTO-CORFU CABLE.—On Wednesday, the 16th instant, Mr. W. A. Killingbeck, the electrician to Henley's Telegraph Works Company, returned to England after effecting the repairs of the above cable. He left this country on the 10th of July, and commenced operations about a week afterwards. The fault was found about $1\frac{1}{2}$ knots from the Otranto end of the cable, and the repairs were completed in three days. We understand that the cable, which was manufactured by Messrs. Glass and Elliott is, for a submersion of over 20 years, in excellent condition. It will be remembered that we noticed the departure of the s.s. *Caroline* on this expedition, in our issue of July 8th. We hear that the same telegraph ship is now chartered by the Eastern Telegraph Company for their cable operations in the Mediterranean.

UNDERGROUND CABLE BETWEEN PARIS AND MARSEILLES.—We read that cast iron pipes are now being made to receive the underground telegraph cable which in a few months will put Paris in direct communication with Marseilles. One hundred and fifty navvies are engaged in this work, which is being prosecuted from both ends along the right bank of the Rhone, and following the main roads. The work is pushed forward with vigour, and it is proposed eventually to connect this cable, which will traverse France from north to south, with the cables of the Mediterranean and Atlantic.

CENTRAL AND SOUTH AMERICAN TELEGRAPHIC COMPANY.—We note the following in the *Panama Sta*-

Herald, dated July 18th: "A cablegram received in this city announces the death at Punta Elena, Ecuador, of Mr. MacLachlan, an operator of the Central and South American Cable Company, who left for that point per *Casma*, on her last trip south. The deceased gentleman had formerly been in the Atlantic cable service, and only arrived here per *Bolivia*, on the 27th of last month. It appears that in riding from the port, Mr. MacLachlan fell from his horse and fractured his skull, dying from the effects late on the 6th inst. Prior to his departure from Panama, he had mentioned the fear he felt at having to ride some distance, never having mounted a horse before in his life, and his melancholy death affords another proof that sometimes the shadow may unwittingly be felt of a coming event. There is no operator for the telegraph company at Punta Elena, and the office will consequently have to remain in the contractor's hands, even should the cables be turned over to the company.

India-Rubber Production in Brazil.—A pamphlet, lately issued in Rio de Janeiro by Senhor Pimenta Bueno, calls attention to the great importance of this product, and the influence it has had on the commerce of Para, the value of whose imports and exports has risen from 26,332,580 mils during the years 1849-1854, to, in 1874-1879, 108,702,684 mils, or fully four times as much during the last five years, while the revenue of the city has increased during the same period from 4,368,527,650 reis to 17,825,895,567 reis, having during the five years previously, say, from 1869 to 1874, reached the large sum of 21,245,591,032 reis. To show the proportionate value of india-rubber, as compared with other exports, the return for 1879-1880 apportions them as follows:—

India-rubber	12,242,500 mils
Castanha nuts	1,473,800 ,,
Cacao	1,032,500 ,,
	14,748,800 ,,

On the other hand, the total exports from the two provinces of Para and Amazonas during the same period was 15,497,600 mils, a striking proof of the position held by india-rubber. It is further stated, that "the provinces of Para and the Amazonas import sugar, coffee, Indian corn, beans, and even mandioca flour." Again, the writer of the pamphlet states that india-rubber occupies the third place in the exports of the empire after coffee and sugar, and yet how few of our readers are probably aware of this fact. Para occupying the extreme northern limits of the empire, with its vast river, the Amazon, flowing past.

The writer shows how, owing to the destructive manner in which the india-rubber trees are cut down, this valuable branch of industry is threatened with serious diminution, if not almost extinction, and urges that means ought to be taken to regulate the cultivation and supply of this valuable article, a conclusion in which most people must agree who feel an interest in Brazil, as well as the great river which gives access from Para to the Andes, and whose banks are covered with primeval forests, many as yet almost untrodden by the foot of man.

A great increase in the value of the article is exhibited, that current being 3,100 reis per kilogramme for fine quality, whereas in the year 1825 it was only worth 300 reis the kilogramme. It may also be noticed that india-rubber contributes 25 per cent of its value to the general and municipal taxes of Para.

Magnetic Units.—We are promised shortly an article on magnetic units by Professor Silvanus Thompson, including an account of a magnetic measuring instrument which he has lately devised. This instrument is, we believe, almost identical with that described in our columns on 12th August, by Mr. F. J. Smith. It is, however, only fair to Professor Thompson to state that he mentioned the existence of his instrument to us before the appearance of Mr. Smith's description.

Personal.—Lieut.-Colonel C. E. Webber, R.E., the President of the Society of Telegraph Engineers and of Electricians, has been suddenly called to Egypt, having been appointed A. Q. M. General on the staff of Sir Garnet Wolseley. We believe the Lieut.-Colonel left England on the 18th instant. Sir Garnet has already had the advantage of Lieut.-Colonel Webber's assistance during the South African campaign of 1879.

We trust that before the meetings of the Society of Telegraph Engineers and of Electricians commence again, the Egyptian affair will be settled and the president once more amongst us, completing the term of office which he has up to the present so worthily and energetically filled. Lieut.-Colonel Webber may rest assured that his career in Egypt will be eagerly watched by many outside military circles.

Burglars and Electricity.—Mr. W. H. Akester, F.S.A., electrician to the Universal Electric Company, Glasgow, has been much annoyed for some months past by midnight burglars attempting to break into his residence at Balvaird, Rutherglen, near Glasgow. He has therefore been under the necessity of devising a plan of adapting electric bells so as to warn him of the approach of burglars, and it has proved at once effective and inexpensive. Late on Wednesday night last week, after the family had gone to bed, a couple of burglars opened the gate, which immediately caused the bell in Mr. Akester's bed-room to ring. From the indicator he knew that they were just entering by the gate. Mr. Akester immediately got out of bed and dressed in haste, by which time the bell rang again, the indicator showing that the thieves were at the front bed-room window, on the ground-floor. Thinking that the servant had not retired for the night, and knowing that the bell is sometimes inadvertently rung when closing the shutters of the window he called over the stair to see whether such was the case. No response was made and he proceeded to the point indicated. The burglars, who by this time had obtained access to the bed-room by the window, must have heard his voice, for, without taking any booty, they immediately cleared the window, took to their heels and decamped. Mr. Akester has had no further annoyance from them since. It is obvious that the application of electricity in the direction indicated above may be greatly extended.

A New Theory.—Those who attended at the City Hall, Glasgow, on the afternoon of Sunday last, heard a new theory propounded by Dr. Hately Waddell on the relationship of electrical science to his Satanic Majesty. Choosing for his text the words, "And I saw an angel come down from heaven having the key of the bottomless pit and a great chain in his hand, and he laid hold of the dragon and bound him a thousand years and cast him into the bottomless pit," Dr. Waddell explained that the terms dragon and devil were figurative expressions for falsehood, ungodliness, &c., and proceeded to ask if our successors on this mundane sphere were in the future to be continually looking up to the clouds for the angel spoken of in the text to come down and bind the devil for a thousand years. If ever angel, Dr. Waddell said, came down from heaven to earth for a work like this it was the angel of electrical science. It came direct from heaven. If such an angel brought a chain in his hand it was the telegraph wire and the submarine cable, coiled up and carried on his arm. If ever such an angel had such a key as spoken of in the text, it was the submarine telegraph. Although a thousand years had not yet been accomplished, they had begun, for of all agencies which human ingenuity, human industry, and courage ever carried out, or will ever carry out, this very agency of electric communication from door to door and from one end of the earth to the other, across deserts, over mountains, and under rivers, and deep oceans like the Atlantic and the Pacific, was the most wonderful. It was unquestionably a revelation from heaven. This was the mode of communication by which the devil himself was to be circumvented, surrounded, bound, and imprisoned, so that he dare not at the peril of his existence utter a lie in the hearing of mankind. If there was any place deeper than the bottom of the Atlantic in this terrestrial globe it would soon be found; and the devil, the father of falsehood, fraud, and imposition, would be sent headlong into perdition. Just in proportion as electricity circled the earth just in that proportion would the devil be defeated!

[If any incentive to work were required in the present state of electrical knowledge here is the golden opportunity.

There is something pleasant in the thoughts that electrical men have contributed in no small way to their own salvation without having been conscious of the fact until brought home to them by Dr. Waddell, "*which is tidings of comfort and joy.*"]

ELECTRICAL PHENOMENA IN THE ALPS, &c.—Mr. A. S. M. Buttemer, in a letter addressed to the *Times*, and dated Lausanne, July 26, gives the following description of some electrical phenomena observed by him during a thunderstorm which took place on the Matterhorn :—"The morning had been fine and warm, but about noon snow fell. On the top the sun came out, and the view on the Italian side was perfectly clear. About five minutes after commencing the descent the sky suddenly became dark, and snow fell in such density that, as one of our party described it, you could grasp a handful from the atmosphere. A peal of thunder made our guides hurry on. Directly afterwards we heard a sharp crack resembling the report of a rifle, and each of us felt a slight shock in the head. A peal of thunder followed instantly. The guide, who was carrying an ice axe, threw it away in alarm. A second and much louder crack followed in about a minute, and we all experienced a powerful shock. The guides felt it in the head, and one of them complained of a severe headache for the rest of the day. My wife described it as passing through the body. I felt it entirely in the knees, which seemed as if momentarily dislocated. Thunder followed immediately as before. After this there were a few distant peals of thunder, and in an hour the snow ceased and the sun came out."

A number of years ago M. Fournets, in an interesting communication brought before the members of the French Academy, showed that on the Alpine and Jura mountain chains exist points which are remarkable for electrical phenomena. The following are some of the effects related in the paper :—

Spontaneous Illumination of the Rocks on Mont Blanc.—During the night of the 11th of August, 1854, Mr. Blackwell was stationed in the Grand Mulets, when the guide, M. Couttet, went out of the little hut about eleven o'clock, and perceived that the edges of all the rocks around appeared as if on fire. He mentioned the fact to his companions without delay, and they all witnessed the phenomenon in question. A storm raged at the time, and under its electrical influence all the edges of the mountains appeared illuminated. Moreover, the clothes of the guides became literally covered with electric sparks, and when they raised their arms into the air their fingers became phosphorescent. At the same time (eleven o'clock at night) heavy rain fell at Lyons, with some thunder in the south-west, and the whole day previously the weather had been very stormy. The same guide, M. Couttet, of Chamounix, when he ascended Mont Blanc on the 25th of August, 1841, in company with M. Chenal, was overtaken by a storm which was extremely dangerous to them, for they were completely surrounded by the lightning. All the rocks and stones about the spot emitted numerous electric sparks, whilst the summit of Mont Blanc and the sky above were perfectly serene.

Electricity on the Breven.—The curious phenomena witnessed by De Saussure, Jalabert, and Pictet on the Breven (altitude 2,520 metres) in 1767 is thus related :—"The weather was very stormy. The travellers had only to extend their fingers or to raise their hands in order to feel a peculiar pricking irritation at their extremities. Pictet was the first to remark this, but the phenomena became in a short time much more intense, and was accompanied by a kind of hissing or buzzing noise. Jalabert, whose hat was ornamented with gold braid, according to the fashion of the period, heard a fearful buzzing noise around his head. Some electric sparks were obtained when the others approached their hands to the gold button on M. Jalabert's hat, or to the iron tip of his walking stick. The storm becoming very violent, the three travellers found it necessary to descend some thirty yards lower down on the mountain side, when they no longer felt these electrical effects.

Electric Snow on the Jungfrau.—On the 10th July, 1863, Mr. Watson and several companions visited the Col de la Jungfrau. The morning had been very fine, but on approaching the Col they perceived that heavy clouds had collected there, and as soon as they reached it the whole party was plunged in a strong gust of wind, accompanied with hail. Forced to return they mistook the road, and wandered for some time in the Latoch-Sittel. At this moment a formidable peal of thunder burst forth, and soon afterwards Mr. Watson heard a kind of hissing noise emanate from his stick. It was like the noise of a kettle boiling on the fire. The sticks and axes carried by the others presented the same phenomena. One of the guides took off his hat, exclaiming that his head was burning; and, in fact, his hair stood on end, like that of Mr. Watson's. The snow during this time emitted a sound similar to what might have been produced by a rapid shower of hailstones. No phosphorescent phenomena were observed, but it is highly probable that lights would have been seen if this had occurred at night. Many of the excursionists received electric shocks more or less intense. At about half-past twelve o'clock the clouds passed away and the above effects disappeared, after having lasted some five-and-twenty minutes.

Electricity on the Piz Surley.—On the 22nd June, 1865, M. A. de Saussure ascended the Piz Surley, starting from Saint Moritz in the Grisons. The Piz Surley is a granite mountain some 2,300 metres high. About one o'clock in the day small hailstones fell abundantly, and a kind of sleet covered the rocky needles and the snow-capped peaks around. The cold increased as our observer arrived at the summit of the Piz Surley about half-past one o'clock. The sleet and hail becoming more abundant, it was determined to make a halt, and to lunch under a pyramid of dry stones which crowns the peak. Resting his stick against this rough construction, Saussure felt a sharp pain in his left shoulder; it was like a pin penetrating slowly into his flesh. Thinking that a pin had found its way into his cloak, he took it off, but the pain only increased, and spread from one shoulder to the other. He then took off his coat, and whilst doing so, discovered the electrical nature of the phenomenon by the peculiar buzzing noise which issued from his stick. A little time afterwards he saw electric radiations emanate from his fingers when he raised his hands in the air. His companions noticed the same curious effects. A thunder-clap towards the west warned them that it was time to leave the summit, and they descended some hundred yards down the mountain. These various effects diminished as the travellers descended, and they stopped when their sticks ceased making any noise. The same day a violent storm broke over the Bernese Alps, and a young English lady on her wedding tour in these mountains was killed by lightning.

Field Lightning in the Jura.—Sometimes certain pasture grounds in the Jura district are seen literally covered by flashes of lightning, hence the phenomenon has been denominated *field lightning*. On the 25th August, 1865, between nine o'clock and mid-day two successive storms were noticed by M. Quiquerez, at Porentray, near Courtavon, at the foot of the Jura. At three o'clock in the afternoon a third storm arose, and the clouds were observed to be very low. Electrical effects manifested themselves with fearful intensity on the entire surface of the fields. The electric flashes succeeded each other with extreme rapidity, and formed long luminous tracts along the pasture land, instead of through the air. The general noise was such as to prevent isolated explosions or decrepitations being heard. No rain fell; but the observers of this strange phenomenon were almost in the cloud itself, and the ground was very wet by the rain which had fallen in the morning. The same day, some three or four leagues to the east of Morimont, along the same chain of mountains, but a few minutes later, fearful lightning played along the surface of the fields and pasture grounds, as if the herbage had been on fire. These storms spread as far as Lyons. Phenomena similar to what has just been narrated are occasionally observed at the surface of lakes and ponds. Arago tells that a farmer of Parthenay, in Vendée, saw a vivid flame spread over a pond during a storm which occurred in the night of the 4th September, 1767, and the next day all the fish in the pond were found dead upon the surface of the water. Something very similar happened on the 2nd August, 1850, at eight or nine in the evening on the Lac de Moret, and more recently on the Lac de Bienne.

THE POST OFFICE AND THE TELEPHONES.—With respe-' to the letter of "Fairplay" which we publish in

"Notes," and referring to that portion of his letter concerning the charge of £10 per subscriber between Leeds and Bradford, we may remind our readers that the Post Office Private wire rentals for the provinces—are, for the wire over house, or underground £7, and for roads £5, per mile per annum. If a double wire is rented the charge per mile is £13 10s. Hence if a single wire is used between Leeds and Bradford the charge will be £70, if a double wire £135. Notwithstanding the "conditions" by "Fairplay," there is evidence from all parts that the development of the telephone has received a great impulse from the Postmaster-General's statement that there should be fair competition.

NEW COMPANY REGISTERED.

MEDICAL CONSTANT CURRENT ELECTRIC COMPANY (LIMITED).—Capital, £100,000, in £1 shares. Objects: To purchase for £48,000 in fully paid shares the letter patent, No. 3443 of year 1882, for an improved medical battery. Signatories (with 1 share each): *H. Stanbrough, Gipsy Hill; *J. Wild Hulseberg, M.R.C.S., Upper Norwood; *William Allison, 22, Grosvenor Mansions; *Major-General C. J. Richards, Southsea; *Major A. Campbell-Walker, Walton-on-Thames; C. F. Tombs, 38, Lombard Street; E. Erskine Scott, 38, Lombard Street.

Directing qualification, £250, in shares. Remuneration, £150 per annnum to each director, with an additional £150 to the chairman. Registered 17th instant by W. T. Manning, 2, Westminster Chambers, Victoria Street.

* Signatories denoted by an asterisk are directors.

NEW PATENTS—1882.

3869. "An improved dynamo-electric motor engine." E. DESFOSSÉS. Dated August 14.

3881. "Electric lamps and conductors therefor." F. R. WELLES. (Communicated by C. E. Scribner and W. R. Patterson.) Dated August 15. (*Complete.*)

3882. "Telephone apparatus (switches)." F. R. WELLES. (Communicated by C. E. Scribner and W. R. Patterson.) Dated August 15. (*Complete.*)

3893. "Secondary or storage batteries." H. J. HADDAN. (Communicated by H. Aron.) Dated August 15.

3906. "Electric lamps or lighting apparatus." W. R. LAKE. (Communicated by P. Tihon and E. Régard.) Dated August 15.

3912. "Strengthening and checking electric currents." P. ADIE and W. S. SIMPSON. Dated August 16.

3941. "Secondary batteries, and methods of constructing the same." N. C. COOKSON. Dated August 17.

3946. "Receiving and recording telegraphic signals." B. H. CHARNEROY. Dated August 17.

3949. "Means or apparatus employed in or for supplying electricity for light, power, or other purposes." T. J. HANDFORD. (Communicated by T. A. Edison.) Dated August 17.

3950. "Dynamo-electric machines, or electric generators, and apparatus connected therewith." S. Z. DE FERRANTI and A. THOMPSON. Dated August 17.

3951. "Improvements in water-motors, and in utilising the force of rivers and streams for the purpose of generating electricity, and in the means employed therefor." S. S. ALLIN. Dated August 18.

3955. "Incandescing electric lamps, and means connected therewith." T. J. HANDFORD. (Communicated by T. A. Edison.) Dated August 18.

3961. "Secondary batteries." T. J. HANDFORD. (Communicated by T. A. Edison.) Dated August 18.

3964. "Improvements in secondary or storage batteries, and apparatus connected therewith." H. T. BENNETT. Dated August 18.

3971. "Improvements in insulating compositions to be used in coating or covering wires and appliances employed in conducting electricity for telegraphic, telephonic, lighting, and other purposes." C. J. ALLPORT and R. PUNSHON. Dated August 19.

3974. "Dynamo electric power creating machines." J. E. T. WOODS. Dated August 19.

3975. "Secondary batteries and electric accumulators." J. E. T. WOODS. Dated August 19.

3976. "Electric lights." T. J. HANDFORD. (Communicated by T. A. Edison.) Dated August 19.

3980. "Improvements in the insulation of wires and other electric conductors used for the production and transmission of electric currents." J. H. JOHNSON. (Communicated by I. M. Hirsch.) Dated August 19.

3982. "Electric signalling apparatus." R. H. BRANDON. (Communicated by H. W. Southwood.) Dated August 19. (*Complete.*)

3991. "Manufacture of incandescing conductors for electric [illegible]" T. J. HANDFORD. (Communicated by T. A. Edison.) August 19.

3995. "Underground conductors for electrical distribution." T. J. HANDFORD. (Communicated by T. A. Edison.) Dated August 21.

3996. "Dynamo and magneto-electric machines for regulating the generation of current by such machines." T. J. HANDFORD. (Communicated by T. A. Edison.) Dated August 21.

4003. "Improved safety devices for use with electric apparatus or conductors designed chiefly for preventing or diminishing fire risks." S. P. THOMPSON. Dated August 22.

4005. "Manufacture and composition of non-conducting tubes for electrical and other useful purposes. J. C. MARSH and R. J. SMITH. Dated August 22.

4025. "Working gear and appliances used in electric lighting." K. W. HEDGES. Dated August 22.

4034. "Generation, storage, distribution, regulation and utilisation of electricity and apparatus or means therefor." J. S. WILLIAMS. Dated August 22.

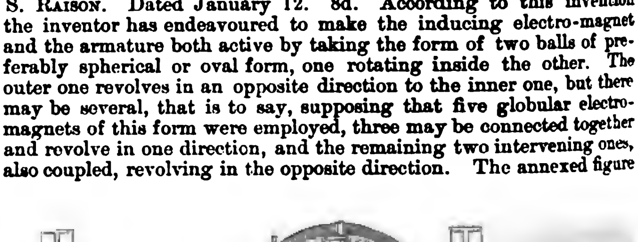
ABSTRACTS OF PUBLISHED SPECIFICATIONS, 1881.

5477. "Electric lamps." W. R. LAKE. (A communication from abroad by C. F. de la Roche, of Paris.) Dated December 14. 6d. Relates to improvements in electric lamps or lighting apparatus. According to the said invention, the inventor develops the voltaic arc in the interior of a chamber or space provided in a block of any kind of refractory material, having in its walls or sides, openings in the form of the frustum of a cone, so as to allow the light produced to emerge in determined directions.

1882.

157. "Apparatus for electric lighting." G. HAWKES. Dated January 11. 8d. Relates to the construction of electric lamps, with a view to simplify the mechanism, shunts, and regulating gear in connection therewith. In constructing an electric lamp according to this invention, the inventor employs mercury or weights for the purpose of forcing the lower or negative carbon by means of tubes into proper position with the upper or positive carbon, and he regulates the ascent of the lower carbon by the varying action of a magnet or solenoid, which is placed in a branch circuit in the lamp. The duty of this magnet is to operate on a movable armature or keeper combined with a clutch or jam ring, turning on two centres, together with a spring descending from the outer one of two screws which operate from the upper one of two metal plates in the negative circuit. This spring in the first instance by its operation prevents the ascent of the lower or metal carbon, but gradually yields and allows it to approach towards the positive carbon, staying the progress, however, of the lower carbon at a proper distance to form the arc and according to the strength of the branch magnet. This action continues until both carbons are consumed or the current be shunted to the next pair.

169. "Electro-motors and dynamo-electric machines, &c." H. S. RAISON. Dated January 12. 8d. According to this invention the inventor has endeavoured to make the inducing electro-magnet and the armature both active by taking the form of two balls of preferably spherical or oval form, one rotating inside the other. The outer one revolves in an opposite direction to the inner one, but there may be several, that is to say, supposing that five globular electro-magnets of this form were employed, three may be connected together and revolve in one direction, and the remaining two intervening ones, also coupled, revolving in the opposite direction. The annexed figure



represents a longitudinal section of a machine constructed in accordance with the invention. a a is the inner core of cast iron, with projections, a^1 a^1, forming pole pieces. This core is cast in two halves, and is mounted on the shaft, x, being fixed thereon by a key, n, and steady pins, b: m is a fixed brass tube, with a groove cut therein to receive the wires, w w, and conduct them to the commutator. The face, g, and collar, p, serve as a guide against which the outer bearings revolve. The core of the outer coil is preferably built up of segments, n^1 n^1, which may be wound separately before fixing in position. The two segments which form the bearings are preferably of brass or other non-magnetic material. A number of openings are left which admit of air circulation to keep the machine cool and to lessen the heating or induction currents, or the core may be made of some non-conductor such as ebonite. The commutator is shown in

the figure, *a* and *b* are complete brass rings, c and c^1 are half rings, *s s* are the brushes pressing on the rings, the course of the currents is shown by the arrows.

178. "Signalling upon railways by means of electricity." C. E. SPAGNOLETTI. Dated January 12. 6d. Has for its object improvements in railway signals and signalling, and is also particularly suitable for working junctions and large station yards, where main lines are intersected by crossings, and shunting operations are frequent or continuous.

231. "Telephonic conductors." C. W. SIEMENS. (A communication from abroad by Frank Jacob, at present on board the steamship *Faraday*, on the high seas.) Dated January 17. 6d. As telephone instruments are usually arranged, a complete circuit is formed including in each case a battery, a sending instrument and a receiving instrument, these two instruments being connected by two insulated wires for the forward and backward electrical currents respectively. The two wires are often twined together in one cord, this having the effect of preventing interference by induction from adjacent wires. When a number of sets of telephonic instruments are employed it is necessary, as they are at present arranged, to provide in the manner described a complete circuit for each receiver, that circuit requiring the two wires as stated above. Now the object of this invention is to render a number of such pairs of wires capable of supplying an increased number of instruments, by arrangements such that one receiver can be worked for each wire instead of one receiver for each pair of wires, as at present. In order to illustrate the invention, let it be supposed that there are two adjacent circuits, A and B, as at present arranged, each circuit having its battery, its sender, its receiver, and its pair of wires, making in all four wires. Now the inventor forms an additional circuit, C, with its battery, sender, and receiver, using the pair of wires of the A circuit for the forward current and the pair of wires of the B circuit for the backward current. There is also formed a fourth circuit, with its battery, sender, and receiver, using the four wires of the C circuit for the forward current and earth for the backward current. In this manner four sets of instruments can be worked by the use of four wires. As another illustration let it be assumed as before that there are the two complete circuits, A and B, and that there are two other similar adjacent circuits, *a* and *b*. There is formed as above described a third circuit, C, by using the pair of wires of A for forward and the pair of wires of B for backward currents, and in a similar manner there is formed another circuit, *c*, by like use of the wires of *a* and *b*, or that there are six circuits with eight wires. But a seventh circuit, D, can be formed by using the four wires of C and the four wires of *c*, and an eighth circuit, E, by using the eight wires of D and earth for return. And thus eight circuits can be effected by the use of eight wires.

In carrying out this invention as above described, any known kind of conductors may be employed, and along with them suitable resistances, condensers, or other known arrangements for determining the various circuits. Fig. 1 of the accompanying drawings illustrates a simple combination in which the two wires, L, connecting two instruments, A and A^1, are utilised as a single line with extensions, l l^1, of any required length for connecting two other instruments, B and B^1, earth, E, being used for the return part of the circuit of the latter pair of instruments. The first instruments, A A^1, are conveniently situated within a bridge, in the limbs of which resistances, R, are introduced, these resistances being arranged so as to equalise the potentials on the two sides of each instrument. Fig. 2 illustrates a combination for working four pairs of instruments with four wires, employing earth for the return part of the circuit of the last pair. In this case the two pairs, A A^1 and A^2 A^3, are connected by their double wires, L L^1, respectively. These two pairs of wires, L D^1, complete a circuit for a third pair of instruments, C C^1, and the four wires of L L^1, with earth for return, complete a circuit for a fourth pair of instruments, D D^1. The instruments, A A^1, A^2 A^3 C C^1, are situated in bridges, with resistances, R, arranged in the limbs of the bridges. As stated above, it is usual to protect telephonic conductors against interference by induction by twining together the pairs of wires forming their respective circuits. When two such pairs are combined to operate for another circuit it is of advantage also to twine together the two strands, each consisting of a twined pair, thus producing a strand which in its turn may be twined with a similar strand when four pairs are combined, and so on according to the number of pairs of wires entering into the combination.

FIG. 1.

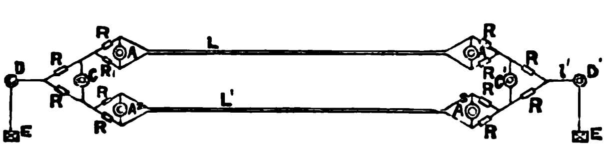


FIG. 2.

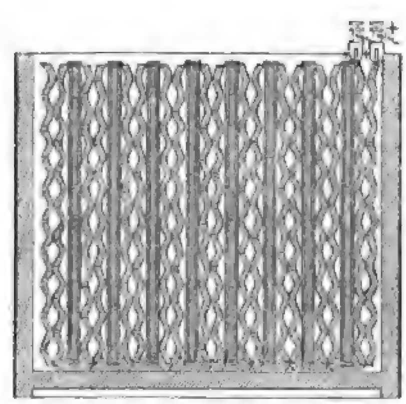
232. "Permanent way for electric and telephonic conductors." H. R. MEYER. Dated January 17. 6d. Relates to an improved permanent way for electric and telephonic conductors, such as wires, or ribbons used for telegraphic electric lighting, telephonic, electric power, and various other like purposes. According to the invention the inventor constructs an underground or subterranean permanent way for electric and telephonic purposes in the following manner. The inventor uses blocks, or slabs, or channels of any suitable non-conducting material such as glass, earthenware, porcelain, terra cotta, cement, or asphalte. The blocks, slabs, or channels are formed of any convenient section, and are tongued and grooved and otherwise attached together end to end. The upper surface of the block, slab, or channel formed with ridges projecting up on each side, and there are also provided such upper surfaces with grooves running longitudinally and the wires, ribbons, or their equivalent, are placed in these grooves. The wires, ribbons, or their equivalent, and all the joints of the permanent way are then covered with a suitable non-conducting material such as asphalte, tar, pitch, resinous gums, cement, paraffin, or stearines. The blocks, slabs, or channels are covered with slabs, flags, or slates of the same material as the blocks, or other suitable material. These covers are pitched to lap the joints of the underneath blocks, and are arranged to lap over each other and over the sides of the blocks, slabs, or channels.

234. "Dynamo-electric machines." W. R. LAKE. (A communication from abroad by C. A. Hussey and Amzi Smith Dodd, both of the City and State of New York.) Dated January 17. 6d. Relates to dynamo-electric machines. It is known that in these machines as ordinarily constructed, only those coils of wire which are passing between the poles or consequent points of the field-magnets are effective in producing currents of electricity, and that the other coils of the armature are for the time rather detrimental than otherwise because they offer a resistance to the passage of the current of electricity produced. One object of the present improvements is to effectually obviate this defect and to this end the said improvements consist in the combination in a dynamo-electric machine, of a field magnet and an armature severally having cores composed of arc-shaped portions wound with wire, intervening arc-shaped portions, and radial portions connecting the two series of arc-shaped portions; the radial portions of both the field-magnet and armature forming poles, polar extensions, or consequent points, and extending towards each other. The field-magnet core will preferably be made of one integral piece of metal and the armature-core of many thin pieces of metal.

245. "Apparatus for regulating electric currents." W. R. LAKE. (A communication from abroad by Achille de Khotinsky, of Paris.) Dated January 17. 6d. This invention has for its object to provide an automatic current regulator which is based on the following principles:—First. To establish, by means of a conductor with variable resistance, a derivation in the circuit of the current operating upon the bobbin of a dynamo-electric machine (either an exciting or a generating machine) before its entrance into the coils of the inducing electro-magnets, and so provide means for varying the electromotive force of the principal current. Secondly. To establish a derivation with variable resistance in the circuit of the current operating upon the bobbin before its entrance into the coils of the electro-magnets, and at the same time to place in the circuit of the current which excites the electro-magnets of the inductor another resistance whereby variations in the intensity of the principal current can be obtained.

252. "Electrical accumulators." H. H. LAKE. (A communication from abroad by La Société Universelle d'Electricité Tommasi, of Paris.) Dated January 18. 6d. Relates to secondary batteries or accumulators, its chief object being to improve the working and increase the power of such batteries by means of a considerable augmentation of the surface of the elements combined with a light weight and small volume. In carrying the said invention into practice each



element of the accumulator is formed of two continuous sheets of lead bent or folded several times and placed in a vessel of gutta-percha or other suitable material in such a manner that a double bend or fold of the one is always contained in a double bend or fold of the other; the sheets being thus placed in juxtaposition at a certain distance from and parallel to each other. The plates are also perforated with holes to allow of the circulation of the liquid. The arrangement is shown by the figure.

278. "Effecting electro-hydo-therapeutic treatment of patients affected by disease." W. A. BARLOW. (A communication from abroad by Messieurs L. Encausse et Canésie, of Paris.) Dated January 19. 6d. The apparatus is disposed in a chamber so that the whole treatment by both the cutaneous absorption and by electricity is effected in a regulated and simultaneous or successive manner. And this will be done without exposing the patient to any change in the temperature, which change is always injurious.

289. "Secondary batteries for storage of electricity." J. HUMPHREYS. Dated January 20. 4d. Relates to improvements in the con-

struction of secondary batteries for storing electricity. It consists in making the plates of which the scondary battery is composed of an open lattice form, that is to say, the sides of the framework of each plate are connected with bars, either of a diamond or oval section, these bars being arranged at an angle on the principle of a "Venetian" blind, thereby exposing a maximum area or surface of spongy lead to the action of the liquid used in the battery.

290. "Telephonic conductors." H. J. Haddan. (A communication from abroad by J. D. Morel, of France.) Dated January 20. 2d. Has for its object to record the conversation carried on through a telephonic conductor by combining with the same a phonograph. (*Provisional only.*)

302. "Voltaic batteries." A. R. Bennett. Dated January 21. 4d. Has for its object the production of a cheap and effective single-fluid voltaic battery. To form the negative portion of the battery the inventor places an electrode of iron or steel packed tightly in small fragments of the same metal, such as iron or steel turnings or borings, or clippings of iron or steel wire, in a solution of potassium monoxide, potassium hydroxide, sodium monoxide or sodium hydroxide. To form the positive portion of the battery, which should be separated from the negative by a porous cell or diaphragm, the same solution is used immersing in it an electrode of zinc, the shape of which is immaterial.

316. "Telephone transmitters." E. G. Brewer. (A communication from abroad by Joseph Olmsted, of New York.) Dated January 21. 6d. Relates to telephone transmitters in which the current from a galvanic battery passing through contact electrodes or points is varied by the impingement of the air waves or vibrations accompanying vocal sounds upon some portion of the instrument to which the electrodes are connected. The invention herein described as applied in connection with transmitters employing a disc or diaphragm, but the novel electrode or contact-piece herein described is applicable to other constructions of telephones, or may be used as a variable contact in a microphone. In telephone transmitters it has heretofore been common to employ but one electrode for making contact with the electrode which receives motion from the diaphragm, and in those cases where a number of electrodes have been employed making contact abreast or in multiple arc with a number of opposite electrodes or a single electrode common to them all, springs have been employed for holding the electrodes in contact and independent adjusting devices have been employed for the various electrodes. This invention consists, first, in a novel construction of telephone in which is employed a series of independently pivoted electrodes forming together a compound electrode, and resting against an opposite electrode by their own gravity, and mounted upon a common adjustable support whereby the same, or practically the same, initial contact is secured for all, and all may be adjusted together for vary-

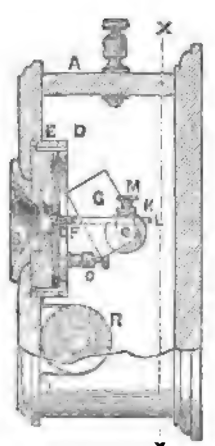


Fig. 1.

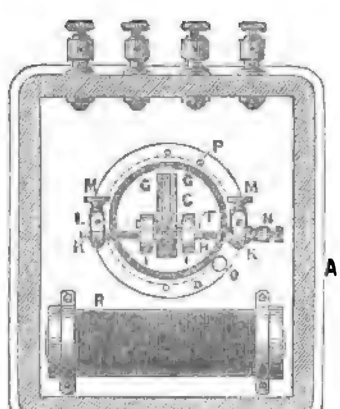

Fig. 2.

ing the contact. In former arrangements employing separate adjusting devices, it is impossible to determine the adjustment that will give the same contact for all, whereas in this arrangement, each electrode being actuated only by an invariable force like gravity, and all having a common adjustable support, the adjustment of the instrument can be accomplished with the certainty that the contact of all the electrodes has been varied to the same extent for all. This invention consists, secondly, in a novel contact or electrode composed of a thin sheet of carbonised paper or cardboard, or of a number of such sheets arranged side by side to make a compound electrode, said sheet or sheets being mounted so as to rest with its edge against the opposite electrode. A compound electrode thus constructed is very constant in its action, and transmits sounds with great volume and accuracy. Instead of carbonised paper a thin sheet of metal, like platinum or german silver, is sometimes used resting in the same manner with its edge against the opposite electrode. In the accompanying drawings fig. 1 is a partial vertical section of a transmitter embodying the invention. Fig. 2 is a rear view of the operative parts of the instrument, the back being removed. A represents the casing of the transmitter, B its mouth-piece, and C the metallic disc or diaphragm which is clamped between a ring, D, and a block, E, in any suitable manner, and is provided at its edge with a rubber dampening ring after a manner common in instruments of this class. F is an electrode which is attached to and moved with the diaphragm. 'ectrode consists of a longitudinal bar, having a bevelled edge ɪvided at or near its centre with a laterally projecting stud ich passes a screw by which said electrode is secured to the gm. The edge of the bar, F, which forms the contact edge, is, by preference, of platinum. G G represent thin sheets of carbonised cardboard or paper strung upon a rod, H, of some conducting material and contained between two blocks, I I, also attached to the rod. The plates, G G, rest with their edges in contact with the edge of the bar electrode, F. The rod, H, is mounted in brackets, K K, which are of hard rubber or similar non-conducting material, and are suspended or attached to rods, L L, mounted upon the clamping ring, D, or any suitable portion of the instrument. The non-conducting brackets may be adjusted horizontally upon the rods, L L, thus carrying with them the supported bar, H, and the electrodes, G, and adjusting the degree of initial contact between the electrodes of the instrument. Upon the end of the conducting-rod, H, is a binding screw, N, which serves for the attachment of one portion of the circuit wire coming from the galvanic battery. Electrical connection is made with the electrode, F, by means of binding-screw, O, which is mounted directly upon the clamping iron, D, of metal, the latter being electrically connected with the diaphragm by means of a screw, P, which passes through the ring, D, and against or into the edge of the diaphragm. M M are set screws which serve to hold the brackets, K, at any desired position upon the rods, L. R represents the induction coil of the transmitter, the primary coil of which makes a portion of a local circuit, including the electrodes, G, F, and a galvanic battery, while its secondary coil is connected to line in the well-known manner. The various parts are electrically connected in the ordinary way well understood in the art, and the instrument operates after the manner of any contact telephone or microphone. The transmission of sounds is, however, accomplished with great distinctness and volume of tone, and the instrument will operate for an indefinite period without adjustment. The carbonised sheets, G G, may be of any desired number, and may be supported after any suitable plan. They are made by carbonising thin sheets of paper, cardboard, or other suitable material after the manner employed in forming the carbon strips of incandescent electric lamps, or in any other suitable manner.

392. "Obtaining light by electricity, &c." W. P. Thompson. (A communication from abroad by the Union Electric Manufacturing Company, of New York.) Dated January 26. 6d. Relates to the electric regulator, described in the number of this Journal for July 29th, page 66.

2416. "Electric batteries." H. H. Lake. (A communication from abroad by J. B. Wallace, of America.) Dated May 22. 6d. The object of the said invention is to construct a battery in which the largest carbon surface may be provided in the smallest space, and in the nearest or most uniform relation to the zinc; and the said invention comprises a glass or equivalent non-conducting covering plate for the battery jar, having a central opening to receive the zinc, and a series of openings around the central opening, combined with a metallic plate resting on the top of the glass cover and having openings corresponding with the openings which surround the central opening, each of the said openings being constructed to receive and hold a "carbon" (that is to say, a rod or piece of carbon) introduced through the openings in the glass cover, and so as to make an electrical connection between all of the carbons, and a connection for one wire with the central zinc independently of the carbon connecting plate, and the said carbon connecting plate being fitted for connection with the other wire.

DISCLAIMER.

The Edison Electric Light Company (Limited). "Systems of conductors for the distribution of electricity, &c." No. 3880. 1880.

CITY NOTES.

Old Broad Street.

THE NATIONAL TELEPHONE COMPANY (LIMITED).

The report of the directors for the year ending 30th June, 1882, states that a reference to the capital account will show the amount expended to 30th June. The directors beg to remind the shareholders that this company took over the businesses of several others, especially in Glasgow, Edinburgh, and Belfast, and has had to amalgamate their various systems. The outlay caused by this amalgamation has been considerable, but it has enabled the company to make important reductions in the staff and expenses. The various exchanges are now in good working order and the service offered to the public in all respects satisfactory. The gross revenue of the company at the 30th of June, 1881, was at the rate of £15,050 19s. 9d. per annum; at the end of the month of June this year, £26,996 3s. 10d., being an increase of 80 per cent. The net profits, after allowing for interest at the rate of 5 per cent. upon calls paid in advance, are £4,217 13s. 2d., which will enable the company to pay the preference shareholders 6 per cent. and to carry over £144 9s. 8d. The amount of rentals and subscriptions credited to the year was £19,243 10s. 11d., and the amount carried forward as gross revenue available for the current year £15,643 5s. 6d. The revenue is steadily increasing, at a higher ratio than the expenditure, and the directors anticipate a much larger profit during the current year. The company have twenty-six exchange licences from the Postmaster-General. The stations for which these licences are held are divided into those completed and contributing to the profits of the company, and those in course of construction, and drawing for their support from capital. There are now nine stations of the former kind, and it is the anticipation of the board that most of the new stations will be added to the self-sustaining list during the current year. The private wire business of the company is also steadily increasing.

Your directors are happy to be able to report that the United Company's defence of its patents in the courts of England and Scotland has been decisive and successful, making good its claim to the possession of the master patents for both transmitter and receiver. They have also pleasure in reporting to the shareholders that the Post-office officials throughout the company's districts act with consideration and courtesy in all their relations with its staff, and that so far as is consistent with the lines laid down by the Postmaster-General, the Department manifests a disposition to avoid placing unnecessary difficulties in the way of the operations of the company. The Postmaster-General has decided to grant exchange licences to responsible parties complying with certain specified conditions. Your directors do not apprehend that this decision will embarrass the transactions of the company, or tell against its prosperity. So long as the United Company's patents are maintained, and equally useful inventions not infringing them remain undiscovered, the decision of the Postmaster-General will not expose the company to legal or serious competition. Practically the company remains in the same position as regards exchange rivalry as if the Postmaster-General had not succeeded in establishing his right of monopoly in the public telegraph system.

On Friday the 18th instant the second annual ordinary general meeting of the shareholders of the above-named company was held at 11, Queen Victoria Street, under the presidency of Col. R. Raynsford Jackson, chairman of the company.

The secretary, Mr. W. B. Campbell, having read the notice convening the meeting,

The Chairman said: Gentlemen, you have all received the directors' report; do you wish to hear it read, or will you take it as read?

The report having been taken as read, the Chairman continued: Gentlemen, I have to move that the report of the directors be accepted and confirmed by the shareholders. It is not my intention to dwell at any great length upon the position and prospects of the company. They are sufficiently, I think, indicated in the balance-sheet and in the report. You will see that the company's income for last year—or rather its revenue at the end of the last year—had reached within a small fraction of £27,000; then the profits for the year were £4,217 15s. 2d., which has enabled the directors to declare a dividend upon the preference shares of 6 per cent. and to carry forward a balance of £144 9s. 8d. One feature in the position of the company, which I think will be regarded as favourable, is that we carry forward £15,643 5s. 5d. towards the gross revenue of the current year. The company's business is divided into two kinds. There is the private wire business, which is entirely independent of the control of the Post-office, for which we do not require the Postmaster-General's licence. That business is on the increase, and I have no doubt that in the course of the current year and in future years it will receive a very large development. For the exchange business we require the Postmaster-General's licence, and it has been the policy of the Postmaster-General up to recently not to grant licences to more than one company in one town. I do not mean to say that there has been no exception to that rule, because in Dundee two existing telephone companies were granted licences. But the Postmaster-General has resolved to alter that rule that there should not be rival telephone companies in one town, and to allow responsible parties applying for licences to the Department to enter into rivalry for the telephone business, for the exchange and branch of the telephone business. This company is under no apprehension whatever as to the consequences of the competition which may arise from the decision which I have just mentioned of the Postmaster-General. In the first place, the company's business is based to a certain extent upon the exclusive license it holds from the United Telephone Company to use its telephones, to act under its patents, and as the United Telephone Company has with great spirit defended its practical and legal possession of the master patents which control the telephone business, the Postmaster-General's licence will not be of any great value to any rivalry. Unless a company enters into the exchange business with full possession of telephones it is practically out of the field. Therefore we do not fear competition. There is another and stronger reason why I do not think we have much to fear from competition of that character, that is that we have the Postmaster-General's licence to establish exchanges in many of the most important towns in the United Kingdom. We have already established exchanges that are giving a good and satisfactory and cheap service, and therefore we do not think that any competitor would have very much chance of successfully taking us in in any way in those places where we have established. The Postmaster-General, in a speech which he made in the House of Commons last Saturday has, whilst indicating his change of policy, made some remarks which, I think, are deserving of attention of all who are interested in the telephonic enterprise. He says that if the private telephone companies do the telephone business better than the Post-office, the Department would be delighted to have all the telephone business of the country conducted by private companies. He says later, if on the other hand it was proved that the business was done better by the Government than by the companies, the Government would have beaten the companies in the open field of competition, and occupy the ground without any question of purchase arising. Now the Postmaster-General is a man of logical mind, who weighs most minutely all his utterances before he puts them into speech before the House of Commons; and I think we may fairly conclude that he has thoroughly made up his mind before making this speech, and we may regard it as indicating truly his purpose. If therefore, he is prepared to welcome the development of the private telephone business, if he will be quite satisfied should the telephone companies beat the Post-office in fair competition, if he is prepared that the competition shall be a fair one, then I think that we have very little to apprehend from the competition of the Post-office; and I am quite convinced that so long as the present Postmaster-General is in office we shall only be opposed by fair competition from the Department. The Department has some advantages over a private company. It is in the position of having a very experienced staff. It has the advantage of being able to rest upon Acts of Parliament. It has also behind it the national purse. On the other hand the private companies have advantages of another kind, upon which they may rely with confidence. They have more elasticity of action; they are better able to secure large and generous support in the various localities; they have representatives of influence and importance in every district where they do business on their board of directors; and they are assisted by local boards and influential gentlemen in the towns where they do business, aiding to carry forward the business of the company. I think the National Telephone Company, constituted as it is and relying as it does on the absolute fairness of the Post-office department—I think that, bearing all these things in mind, the National Telephone Company may rest perfectly satisfied upon the basis upon which its business rests. I have to point out to the shareholders that there has been a loss during the current year in the trunk business of the company, and it may be necessary that I should explain what the character of that business is. When the Postmaster-General agreed to grant exchange licences to the various companies, he determined to keep the trunk business, that is the telephonic business between town and town, because he apprehended that if he did not the Post-ffice would lose very considerably in its postal telegraph revenue. After representations made to him he agreed that the Post-office should itself erect communications between our central exchanges in different towns. For example, the Postmaster-General has given us communication between Leeds and Bradford by a wire erected by the Post-office, but the terms upon which that privilege was granted us was upon terms that we should pay the Postmaster-General for eight subscribers, whether we obtained eight or not, and we have, in order to develop the telephonic enterprise in our various districts, run the risk of paying the Postmaster-General for a trunk wire, without having in the first instance secured eight subscribers. In some places we have only three subscribers where we have paid for eight. You will say, perhaps, that it was unwise for the company to have agreed with the Postmaster-General for the erection of these wires without having first secured the number of subscribers required by the Postmaster-General. It was, however, thought that it was necessary in the public interest and for the sake of developing the telephonic enterprise to run some risk, and in Yorkshire we ran the risk of coupling up the various towns in which we are interested, and agreeing to pay the Postmaster-General for nine different trunk wires. One effect of the course we have pursued is that the *Leeds Mercury* has become a subscriber to every one of our wires and to every one of our exchanges, and it is thus enabled to hold communication with its agents in Yorkshire a minute or two before going to press. Now, had we not run some risk of incurring some loss in adopting the trunk system the *Leeds Mercury* would not have been able to do that, and the force of its example on the telephonic enterprise would have been lost. I have an idea that there will be before long a change in the decision of the Department with regard to the trunk system. The inclination of the Postmaster-General and of the Post-office is to feel its way, and as it discovers that the alteration is beneficial to the public and the companies, without being detrimental to the interests of the Department, it is disposed to make changes which seem to be indicated as wise by the circumstances. I have great confidence that before we next meet the shareholders at an annual meeting I shall be able to announce that the trunk system is on a better footing. I am sure we should be, if we were as free with the trunk system as with the exchange. I have thought it necessary to enter into these explanations for two reasons, one that the shareholders may understand our position in this important matter, and that our subscribers may understand that we are giving them this service at a loss to the company. There is nothing further of moment that it is necessary to bring before the shareholders. I think they will be satisfied with the progress that the company has made, and I feel confident we shall be able to put before you another year a better and more favourable report, showing a larger balance on the year, and I have great confidence in the success of our enterprise. I may, however, return to the Post-office in order to refer to a matter of the Postmaster-General's, which, I think, it is well that I should make reference to. The Postmaster-General is apprehensive lest the idea that the Government intends taking over the telephone companies should lead to speculation in the shares, and thus undoubtedly enhance their value. I must say that, for this company, I learn with great satisfaction that the Postmaster-General has no idea of purchasing the telephone companies. When the Postmaster-General granted to us the exchange licences, he reserved to himself the right to take over the companies at certain periods upon valuations based upon certain principles. I think he proposed to take over the exchanges in 1890. If I could put him off till 1990 I should be glad (laughter). Therefore I learn that it is not the intention of the Postmaster-General to buy up the telephone companies. We ask only to be left free to enter into competition with the Post-office and other telephone companies, and we shall then have the fruit of our enterprise without the risk of having it taken over by the Government. I beg to move the adoption of the directors' report by the shareholders.

Mr. W. A. Smith said he rose to second the adoption of the report, but after the Chairman's very exhaustive statement, he did not think there was very much left for him to say. He could only heartily endorse all that he had said. He should like to point out to them one of the best features in the report. It was called the second annual meeting, but it really was the first, for their first annual meeting was almost a statutory meeting, as it was held very shortly after the formation of the company. In the brief space of one year, then, they had more than doubled their revenue. He did not require to point out to them the good point that was in the balance-sheet, because there were many charges fixed, or practically fixed. If their revenue went on in future years as it had done in the past the result could not fail to be highly satisfactory to the shareholders.

The proposition was then put by the Chairman and carried unanimously.

The re-election of the following retiring members of the board, Messrs. Jeremiah Garnett, John Bruce, and W. A. Smith was proposed by the Chairman, and having been duly seconded they were accordingly declared members of the board.

The Chairman also proposed the re-election of the auditors of the company, Messrs. Quilter, Ball & Co., which, having been seconded by Mr. W. A. Smith, was declared carried.

Mr. F. F. Begg (Edinburgh), in proposing a vote of thanks to the chairman and directors, said they had listened with pleasure to his exposition of the position of the company. He thought Colonel Jackson had shown them very clearly that he had a thorough grasp of the whole subject, and did not neglect any opportunity of advancing the interest of the company. But there was one matter upon which he did not enter, and to which he should like to refer. They might suppose that in making up a report the figures were made up from theoretrical knowledge, but he knew of his own knowledge that Colonel Jackson had made repeated visits to all the centres of the company during the year. He had gone as far north, he believed, as Aberdeen, certainly to Dundee. In fact, he had done the work of a general manager. He would be the last, he knew, to take all the credit to himself, for he was surrounded by a board of directors who seconded his efforts to the best of their power. He would, therefore, move that the thanks of the meeting be given to the chairman and directors.

Mr. C. J. Bell seconded.

The Chairman briefly returned thanks for himself and his colleagues. The board, he said, were representative men in their respective districts; they were men of energy and business, and had been selected for their local influence and business capacity.

The proceedings then terminated.

THE SOUTH EASTERN BRUSH ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

ON Thursday afternoon an extraordinary general meeting of the members of this company was held at the Cannon Street Hotel, under the presidency of Sir Michael Kennedy, for the purpose, if thought proper, of confirming the following special resolutions modifying the Articles of Association, passed at the extraordinary general meeting of the company held on the 9th inst., viz.:—"That the Articles of Association of the company be, and the same hereby are, altered as follows:—(1) By the insertion of the following words at the end of Article 4: 'Provided always that no share shall be issued at a discount without the sanction of a general meeting;' (2) by the alteration in Articles 81 and 89 of '1886,' therein mentioned, to '1884.' (3) By the omission of Articles 85 and 100."

There being just a quorum of shareholders present,

The Secretary, Mr. Alfred Jermyn, having read the notice convening the meeting,

The Chairman said: Gentlemen, we have met here only for the formal purpose of confirming the resolution which we passed at our last special meeting. There is no other business to be done at this meeting, and I need not address you at any length upon this matter. I merely propose the resolution which has been read to you, and I suppose you will take it as read?

Mr. Fry (a Director): I will second that.

The Chairman then put the resolution to the meeting, and it was carried unanimously.

PROVINCIAL (BRUSH) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

SIR MICHAEL KENNEDY presided on Thursday over an extraordinary general meeting of the members of this company, held at Cannon Street Hotel, for the purpose, if thought proper, of confirming the following special resolutions, modifying the Articles of Association, passed at the extraordinary general meeting of the company held on the 9th inst., viz.:—"That the Articles of Association of the company be, and the same are hereby, altered as follows:—(1) By the insertion of the following words at the end of Article 4:—'Provided always that no share shall be issued at a discount without the sanction of a general meeting.' (2) By the alteration in Articles 81 and 89 of '1886,' therein mentioned, to '1884.' (3) By the omission of Articles 85 and 100."

The notice convening the meeting having been read by the Secretary, Mr. Alfred Jermyn,

The Chairman said: Gentlemen, our meeting is very special, and I think will be very brief. It is merely called that I should move the resolution which you have heard read by the secretary, which is confirmatory of the resolution passed on the occasion of the last meeting. I beg to move the resolution which has been read to you by the secretary.

Mr. Fry (a Director): And I beg to second it.

The resolution having been put to the meeting was carried unanimously, and the proceedings terminated.

BRUSH MIDLAND ELECTRIC LIGHT AND POWER COMPANY, LIMITED.—The directors have elected Mr. R. H. Glyn as chairman.

LONDON AND GLOBE TELEPHONE AND MAINTENANCE COMPANY.—The letters of allotment of this company have been ·ted.

WESTERN UNION TELEGRAPH COMPANY.—Messrs. Morton, Rose and Company notify the payment on September 1 of the interest due on the bonds of this company's Six per Cent. Sterling Loan.

BIRMINGHAM MUSICAL FESTIVAL.—There is to be a somewhat extensive installation of Electric Light at this festival, the work being undertaken by Mr. Crompton, in conjunction with Messrs. Winfield & Co. Twelve Bürgin machines are to be used, driven by a 120 horse-power engine; these to be stationed about 200 to 300 yards away from the hall.

TRAFFIC RECEIPTS.

The Eastern Telegraph Company. The traffic receipts for July were £31,608, against £33,171 in the same month of 1881.

The Western and Brazilian Telegraph Company, Limited. The traffic receipts for the five weeks ending 21st and 28th July and 4th, 11th and 18th August, 1882, were £1,623, £1,882, and £1,661, £1,718, £1,752, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited.

West India and Panama Telegraph Company (Limited). The estimated traffic receipts for the half-month ended the 15th August are £2,382, as compared with £1,704 in the corresponding period of 1881. The May receipts, estimated at £6,542, realised £6,501.

Electrical Review.

Vol. XI.—No. 249.

ASSOCIATION FRANÇAISE POUR L'AVANCEMENT DES SCIENCES.

(*From our own Correspondent.*)

ELEVENTH SESSION.

August 24th to 31st, held at La Rochelle.

General Opening Sitting.

The eleventh meeting of the "Association Française pour l'Avancement des Sciences" was opened on August 24th, 1882, at half-past two o'clock p.m., under the presidency of M. Janssen, a member of the institute.

M. Janssen thanked La Rochelle for its sympathetic reception and called attention to the gratitude which it owes to one of its members, M. Brunet, a wealthy merchant of the French Antilles, lately deceased, who left a considerable fortune to the association, a fortune of which it will make the best use in the interests of the progress of science.

According to custom, M. Janssen, who has devoted all his time and all his knowledge to the study of physical astronomy, took for the subject of his speech: "The Condition of Physical Astronomy." He showed how this science, purely descriptive at its commencement, soon developed into celestial mechanics and tends now to become, with the aid of lenses, of spectrum analysis, and of photography, a physical science. He showed what advantages can be derived from the new photographic processes, which, owing to their exquisite sensibility, enable the sun to be photographed in one hundred thousandth part of a second, and predicted that before long the gelatine plate would become the veritable retina of the *savant*.

After the remarkable speech of M. Janssen, of which we can only indicate the principal points in a review devoted specially to the progress of electricity, M. S. Dor, Mayor of La Rochelle, welcomed the members of the association, and pointed out the numerous subjects of study which could be found in the department of La Charente-Inférieure.

M. Emile Trélat, Professor at the Conservatoire des Arts et Métiers, general secretary of the association, then alluded to the history of La Rochelle; he touched upon the homage due to deceased members, the honours accorded to a large number of the members of the association, and described the salient features of the tenth session, held at Algiers in the spring of the year 1881.

M. G. Masson, treasurer, then gave a report of the increasing prosperity of the financial condition of the association, which numbers at present more than 4,000 members. After this speech the meeting concluded, and the members met in their respective sections to proceed to the nomination of offices, and to fix the order of the section sittings.

Section Sittings.

The association is divided into four groups; the first devoted to mathematical science, the second to physical and chemical science, the third to natural science, and the fourth to economic science. These groups are themselves sub-divided into sections to the number of fifteen. We will only give account here of the labours of the fifth section—Physics—which holds its sittings in the physical laboratory of the Lycée de La Rochelle.

PHYSICAL SECTION.

Sitting of the 24th of August.

President—M. Lallemand, doyen de la Faculté des Sciences de Poitiers.

Secretary—M. Leblond, professor of the torpedo school at Boyardville.

The members of this section, very few in number, at the first sitting separated, fixing the order of procedure, which it is useless to give here, since we shall devote an analysis, more or less detailed, to each of the electrical subjects treated of in each sitting.

Sitting of the 25th of August.

NEW ELECTRO-DYNAMIC BALANCE.

(*For figure see next page.*)

By M. Debrun, Professor at the Lycée de Pau.

The inventor sought to construct an instrument at once easily worked, sensitive, and exact. The apparatus is composed of a pair of fixed bobbins and a pair of movable bobbins, placed at both ends of a horizontal beam. The current to be measured traverses these four bobbins, arranged in circuit in such a manner that the two fixed bobbins repel the movable bobbins placed upon the beam. To protect the system from the action of terrestrial magnetism the beam is placed perpendicularly to the plane of the magnetic meridian. The beam supports two scale-pans, intended to hold the weights, which give equilibrium to the system. The method consists of balancing the dynamic action of the current by weights, until the beam recovers its equilibrium, and the spirals of the bobbins are at the same relative distance asunder.

To avoid the use of weights, which is inconvenient, M. Debrun combined a hydraulic *compensator*, which replaces them. Under one of the scale-pans is fixed a platinum cylinder, dipping half-way into water.

By altering the height of the liquid the pressure is altered. Knowing the diameter of the platinum wire, and the variation of the level of the liquid, one easily deduces the value of the pressure. M. Debrun increases the sensitiveness of the apparatus by making use of a large cylindrical vase, in communication with a tube and a narrow graduated gauge. Equilibrium is restored by forcing the water backwards or forwards by the aid of an india-rubber bulb, worked by a screw and fixed to the end of it; thus readings are more easily and more exactly taken upon a graduated scale, occupying the length of the gauge. For accurate experiments, M. Debrun brings the balance always to the same position by providing the extremity of the needle of the balance with a net formed of spider's web, and by making use of a micrometer microscope. It is with an apparatus of this kind, divided for the purpose, that M. Debrun has examined the electrical discharges produced by surfaces of mercury vibrating in liquid conductors.

For intense currents, such as those employed for the electric light, M. Debrun replaces the hydrostatic pressure by a spiral spring, which is stretched more or less by means of a graduated screw.

RESEARCHES UPON THE PHOTOMETRIC COMPARISON OF VARIOUSLY COLOURED SOURCES.

Paper by MM. Macé de Lépinay and N. Nicati, read by M. Marcel Brillouin.

This question, apparently foreign to the subject which we are treating, is nevertheless directly attached to it, and is especially interesting to electricians who are in search of a simple, and above all, exact photometric process.

Two quantities of light may be considered equal when they illuminate the same colourless object (black upon a white ground, such as printed characters) placed always at the same distance from the same observer, and make him perceive the details of it with the same clearness, that is to say, when both quantities of light present the same clearness of outline.

We can, besides, consider two quantities of light as equal when they illuminate two colourless surfaces (white) and these surfaces appear equally illuminated; for example, in the Rumford photometer, when they give two shadows of the same intensity.

Unfortunately, it is difficult to appreciate the equality of clearness of two neighbouring surfaces differently coloured—for example, one blue and the other yellow. It is necessary in such a case to limit considerably the illuminated surfaces, as the smaller a surface is the less can the eye estimate its colouring.

The two methods above, based, one upon clearness of outline, the other upon the equality of illumination of two neighbouring surfaces,

The proposition was then put by the Chairman and carried unanimously.

The re-election of the following retiring members of the board, Messrs. Jeremiah Garnett, John Bruce, and W. A. Smith was proposed by the Chairman, and having been duly seconded they were accordingly declared members of the board.

The Chairman also proposed the re-election of the auditors of the company, Messrs. Quilter, Ball & Co., which, having been seconded by Mr. W. A. Smith, was declared carried.

Mr. F. F. Begg (Edinburgh), in proposing a vote of thanks to the chairman and directors, said they had listened with pleasure to his exposition of the position of the company. He thought Colonel Jackson had shown them very clearly that he had a thorough grasp of the whole subject, and did not neglect any opportunity of advancing the interest of the company. But there was one matter upon which he did not enter, and to which he should like to refer. They might suppose that in making up a report the figures were made up from theoretrical knowledge, but he knew of his own knowledge that Colonel Jackson had made repeated visits to all the centres of the company during the year. He had gone as far north, he believed, as Aberdeen, certainly to Dundee. In fact, he had done the work of a general manager. He would be the last, he knew, to take all the credit to himself, for he was surrounded by a board of directors who seconded his efforts to the best of their power. He would, therefore, move that the thanks of the meeting be given to the chairman and directors.

Mr. C. J. Bell seconded.

The Chairman briefly returned thanks for himself and his colleagues. The board, he said, were representative men in their respective districts; they were men of energy and business, and had been selected for their local influence and business capacity.

The proceedings then terminated.

THE SOUTH EASTERN BRUSH ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

On Thursday afternoon an extraordinary general meeting of the members of this company was held at the Cannon Street Hotel, under the presidency of Sir Michael Kennedy, for the purpose, if thought proper, of confirming the following special resolutions modifying the Articles of Association, passed at the extraordinary general meeting of the company held on the 9th inst., viz.:—"That the Articles of Association of the company be, and the same hereby are, altered as follows:—(1) By the insertion of the following words at the end of Article 4: 'Provided always that no share shall be issued at a discount without the sanction of a general meeting;' (2) by the alteration in Articles 81 and 89 of '1886,' therein mentioned, to '1884.' (3) By the omission of Articles 85 and 100."

There being just a quorum of shareholders present,

The Secretary, Mr. Alfred Jermyn, having read the notice convening the meeting,

The Chairman said: Gentlemen, we have met here only for the formal purpose of confirming the resolution which we passed at our last special meeting. There is no other business to be done at this meeting, and I need not address you at any length upon this matter. I merely propose the resolution which has been read to you, and I suppose you will take it as read?

Mr. Fry (a Director): I will second that.

The Chairman then put the resolution to the meeting, and it was carried unanimously.

PROVINCIAL (BRUSH) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

Sir Michael Kennedy presided on Thursday over an extraordinary general meeting of the members of this company, held at Cannon Street Hotel, for the purpose, if thought proper, of confirming the following special resolutions, modifying the Articles of Association, passed at the extraordinary general meeting of the company held on the 9th inst., viz.:—"That the Articles of Association of the company be, and the same are hereby, altered as follows:—(1) By the insertion of the following words at the end of Article 4:—'Provided always that no share shall be issued at a discount without the sanction of a general meeting.' (2) By the alteration in Articles 81 and 89 of '1886,' therein mentioned, to '1884.' (3) By the omission of Articles 85 and 100."

The notice convening the meeting having been read by the Secretary, Mr. Alfred Jermyn,

The Chairman said: Gentlemen, our meeting is very special, and I think will be very brief. It is merely called that I should move the resolution which you have heard read by the secretary, which is confirmatory of the resolution passed on the occasion of the last meeting. I beg to move the resolution which has been read to you by the secretary.

Mr. Fry (a Director): And I beg to second it.

The resolution having been put to the meeting was carried unanimously, and the proceedings terminated.

Brush Midland Electric Light and Power Company, Limited.—The directors have elected Mr. R. H. Glyn as chairman.

London and Globe Telephone and Maintenance Company.—The letters of allotment of this company have been posted.

Western Union Telegraph Company.—Messrs. Morton, Rose and Company notify the payment on September 1 of the interest due on the bonds of this company's Six per Cent. Sterling Loan.

Birmingham Musical Festival.—There is to be a somewhat extensive installation of Electric Light at the Festival, the work being undertaken by Mr. Crompton, in conjunction with Messrs. Winfield & Co. Twelve Bürgin machines are to be used, driven by a 120 horse-power engine; these to be stationed about 200 to 300 yards away from the hall.

Vol. XI.—No. 249.

ASSOCIATION FRANÇAISE POUR L'AVANCEMENT DES SCIENCES.

(*From our own Correspondent.*)

ELEVENTH SESSION.

August 24th to 31st, held at La Rochelle.

General Opening Sitting.

The eleventh meeting of the "Association Française pour l'Avancement des Sciences" was opened on August 24th, 1882, at half-past two o'clock p.m., under the presidency of M. Janssen, a member of the institute.

M. Janssen thanked La Rochelle for its sympathetic reception and called attention to the gratitude which it owes to one of its members, M. Brunet, a wealthy merchant of the French Antilles, lately deceased, who left a considerable fortune to the association, a fortune of which it will make the best use in the interests of the progress of science.

According to custom, M. Janssen, who has devoted all his time and all his knowledge to the study of physical astronomy, took for the subject of his speech: "The Condition of Physical Astronomy." He showed how this science, purely descriptive at its commencement, soon developed into celestial mechanics and tends now to become, with the aid of lenses, of spectrum analysis, and of photography, a physical science. He showed what advantages can be derived from the new photographic processes, which, owing to their exquisite sensibility, enable the sun to be photographed in one hundred thousandth part of a second, and predicted that before long the gelatine plate would become the veritable retina of the *savant*.

After the remarkable speech of M. Janssen, of which we can only indicate the principal points in a review devoted specially to the progress of electricity, M. S. Dor, Mayor of La Rochelle, welcomed the members of the association, and pointed out the numerous subjects of study which could be found in the department of La Charente-Inférieure.

M. Emile Trélat, Professor at the Conservatoire des Arts et Métiers, general secretary of the association, then alluded to the history of La Rochelle; he touched upon the homage due to deceased members, the honours accorded to a large number of the members of the association, and described the salient features of the tenth session, held at Algiers in the spring of the year 1881.

M. G. Masson, treasurer, then gave a report [illegible] creasing prosperity of the financial con[illegible] ciation, which numbers at present [illegible] bers. After this speech the [illegible] members met in their resp[illegible] nomination of offices [illegible] sittings.

The associati[illegible] devoted to mathe[illegible]

[illegible] copper tube. [illegible] concentrically round the axle o, o'. [illegible] ng the weight P. [illegible] e magnet, bearing two knife edges upon its axis. [illegible] of this magnet is an iron tube, surrounded by [illegible] be, to which a rapid rotary motion is imparted. The [illegible] nduction tend to attract the magnet in the direction of the [illegible] on, and it is necessary, in order to maintain equilibrium, [illegible] alance this action by the aid of a counterpoise,* sus-

[illegible] d-indicator properly so called, the magnet, which has been properly [illegible] ed at a certain angle dependent on this speed, and it is this angle [illegible] of its determination.

[illegible]

President—M. [illegible] Sciences de P[illegible]

Secretary—[illegible] at Rochefort.

The members of [illegible] first sitting [illegible] it is useless [illegible] more or less [illegible] treated of in each sitting.

SITTING OF THE [illegible]

NEW ELECTRO[illegible] BALANCE.

By M. [illegible]

[illegible]

To avoid the use of weights [illegible] M. Debrun [illegible] combined a hydraulic [illegible] of the scale-pans is fixed a platinum [illegible] dipping half-way into water.

By altering the height of the liquid the pressure is altered. Knowing the diameter of the platinum wire and the variation of the level of the liquid, one easily deduces the value of the pressure. M. Debrun increases the sensitiveness of the apparatus by making use of a large cylinder [illegible] graduated gauge. [illegible] backwards or forwards by the aid of [illegible] by a screw and fixed to the end [illegible] and more exactly taken upon a graduated [illegible] of the gauge. For accurate experiments M. Debrun brings the balance always to the same point [illegible] the extremity of the needle of the balance with a [illegible] and by making use of a micrometer microscope. [illegible] an apparatus of this kind, divided for the purpose, that M. Debrun has examined the electrical discharges produced by surfaces of [illegible] vibrating in liquid conductors.

For intense currents, such as those employed for the electric light, M. Debrun replaces the hydrostatic pressure by a spiral spring, which is stretched more or less by means of a graduated screw.

RESEARCHES UPON THE PHOTOMETRIC COMPARISON OF VARIOUSLY COLOURED SOURCES.

Paper by MM. Macé de Lépinay and N. Nicati, read by M. Macé de Lépinay.

This question, apparently foreign to the subject which we are treating, is nevertheless directly attached to it, and is especially interesting to electricians who are in search of a simple, and above all, [illegible] metric process.

[illegible] of light may be considered equal when they illu[illegible] the me[illegible] a white ground [illegible] ingenious [illegible] the principle to [illegible] always at the same distance from the [illegible] the details of it with the same [illegible] tities of light present the [illegible] as equal when [illegible] surfaces [illegible] meter,

SITTING OF THE 28TH [illegible]

ELECTRICAL INCANDESCENT LAMP[illegible] OPEN AIR.

By M. Emile Reynier.

The process of incandescence in the open air, which [illegible] known in 1878, is now abandoned. Various causes bro[illegible]

are evidently equivalent when luminous sources of the same colour are being tested. For variously coloured lights, the experiments of M. Siemens and those of MM. Macé de Lepinay and Nicati prove that they are inapplicable.

Two quantities of light capable of giving two shadows of the same clearness, will not make equally distinct, black printed characters upon a white ground.

MM. Macé de Lepinay and Nicati have, therefore, undertaken some comparative experiments, and have established numerical relations which have led them to conclusions particularly interesting to electricians. We will reproduce them here.

It is quite evident that the principal object of public and private illumination is not to produce upon the eye a more or less intense sensation of light, but rather to enable us to distinguish what is round about us. Consequently, with equal illuminating power, there is evidently every advantage in the employment of a yellow illuminating source—intense gas jets or electric incandescent lamps—in preference to the employment of a source rich in blue rays, as is the electric arc.

This conclusion results from the fact that experiments made by both methods lead to results that correspond for all radiations *less* refrangible than greenish yellow, but that completely differ for radiations *more* refrangible.

Also, in order to characterise the practical value of a source of light, it is not sufficient to give its value in Carcels, a value deduced from the comparison of the shadows produced by these two sources, but there will be every advantage in determining at the same time the illuminating power of the source by a method deduced from clearness of outline. In this manner two numbers would be obtained which in some cases might be widely different, according to the nature of the source employed.

SITTING OF THE 26TH AUGUST, 1882.

LIGHT BICHROMATE OF POTASH BATTERY.

Result of the preliminary experiments performed by the aid of a dynamo-electric motor actuating an aerial screw.)

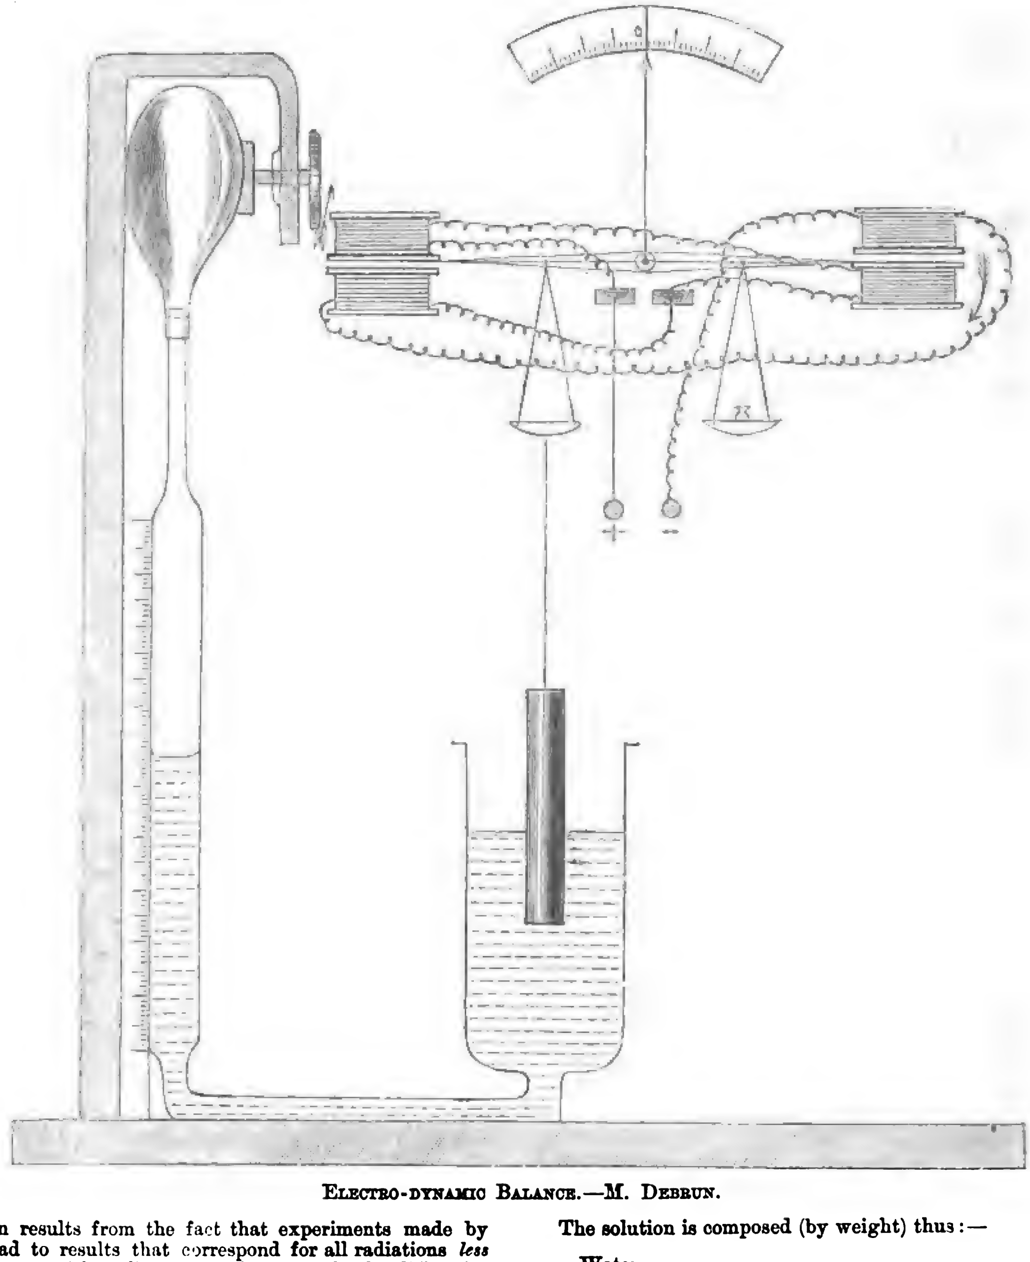
By M. GASTON TISSANDIER.

The writer proposed in his researches to realise the experiment made by M. Giffard in 1852 with a steam motor, making use of an aerial screw actuated by an electric motor. Its employment presents two advantages—absence of fire and constancy of weight. After having made experiments on a small scale with accumulators and bichromate of potash batteries on the model of M. Trouvé, and calculated that the bichromate batteries present greater constancy than is commonly supposed, M. Tissandier conceived the idea of the model which we shall describe, giving the results obtained from it.

Each element is composed of a parallelopipedical trough of ebonite, containing 10 plates of zinc alternated with 11 carbon plates. The weight of each element is expressed thus:—

	Grammes.
Zincs	1,200
Carbons	900
Ebonite vessel	860
Liquid (about four litres)	4,800
Accessories	200
Total	7,960

Or *eight* kilogrammes, in round numbers.



ELECTRO-DYNAMIC BALANCE.—M. DEBRUN.

The solution is composed (by weight) thus:—

	Parts.
Water	100
Bichromate of potash	16
Sulphuric acid	37

With the addition of a little bisulphate of mercury to maintain the amalgamation of the zincs. The great concentration of the solution diminishes the internal resistance of the element, increases its discharge per unit of time, and reduces the weight of water, which is a dead weight, to its minimum.

The constants of the element are:—

$$E = 2 \text{ volts.}$$
$$r = 0{\cdot}01 \text{ ohm.}$$

A battery of 18 elements in tension weighs 140 kilogrammes. [illegible] can supply upon an external circuit of 0·54 ohm resistance a c[illegible] of 50 ampères for about an hour and a half, and a usefu[illegible] force of 135 kilogrammètres per second, from which could [illegible] 100 kilogrammètres of effective work (1¼ horse-power [illegible] 90 minutes.

We will pass over the description of the screw [illegible] the motor.

The motor is a continuous current dynamo [illegible]

on the Siemens system, constructed and adapted specially for this purpose at the Siemens establishment at Paris, directed by M. Boistel.

All its parts, except the induced part, are of cast-steel, but they have been reduced to a minimum of weight and dimensions, for the machine, constructed to furnish 100 kilogrammètres with a current of 50 ampères, making 1,200 revolutions, only weighs 55 kilogrammes.

The battery and the machine, therefore, weigh no more than 200 kilogrammes; an elongated balloon of 1,000 cubic metres, 27 metres long and 9 metres diameter at the centre, is sufficient to support them. With a machine giving 100 kilogrammètres and a screw of 2·85 m. diameter, making 100 revolutions per second, M. Tissandier expects to obtain an average speed of 4 metres per second, which will allow him to deviate sensibly from the line of the wind, and even to direct himself in any direction in calm weather.

ON THE METHODS OF COMPARING THE CO-EFFICIENTS OF INDUCTION; CAUSES OF ERRORS, AND MEANS OF PREVENTING THEM.

By M. MARCEL BRILLOUIN.

The nature of this communication, of an order at once theoretical and experimental, does not admit of a succinct analysis, and could find no place here except with developments, which would lead us out of the course which we have traced for ourselves.

REGISTERING CAPILLARY ELECTROMETER.

By M. E. DEBRUN.

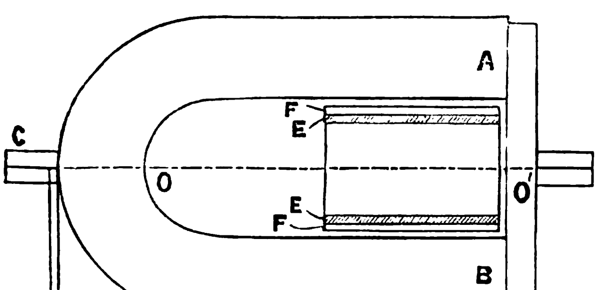
In certain investigations which demand an almost continuous observation of the difference of potential between two given points, it is very fatiguing to observe and record the variations of height of the column of mercury of the electrometer.

M. Debrun has combined, with the object of suppressing this fatigue, and of obtaining continuous and more precise results, a recording system, which is ingenious, but rather complicated. It would be impossible to make the mechanism understood without the assistance of a figure.

ELECTRO-MAGNETIC DETERMINATION OF THE MECHANICAL EQUIVALENT OF HEAT.

By M. MARCEL DEPREZ.

The experiments hitherto made to determine the mechanical equivalent of heat have given numbers which vary between 420 and 432. The errors arise chiefly from the imperfect process which serves to determine the labour expended. The method proposed by M. Marcel Deprez depends in principle upon a measurement of the effects of induction in the Foucault disc. To understand this method, it is necessary, in the first place, to remember the magnetic speed-indicator of M. Marcel Deprez. This apparatus is composed of



SPEED-INDICATOR.—MARCEL DEPREZ.

A, B. Horse-shoe magnet.
C, D. Knife edges.
E. Iron tube. F. Copper tube.
The two tubes turn concentrically round the axle O, O'.
L. Lever supporting the weight P.

m

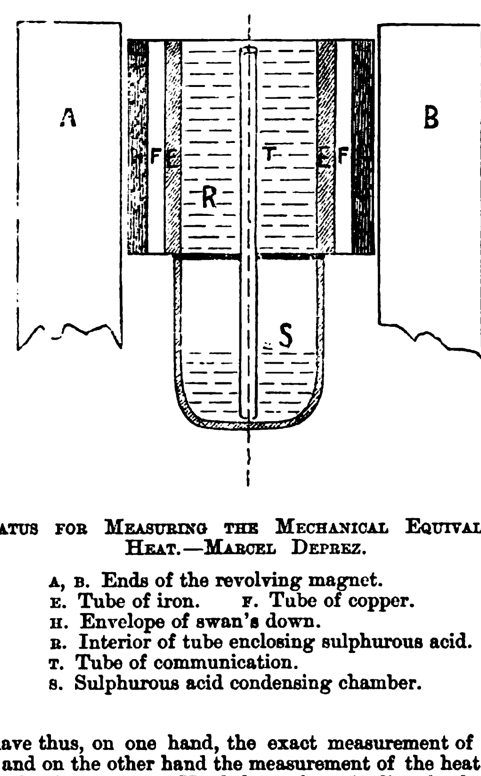
nomi a horizontal horse-shoe magnet, bearing two knife edges upon its axis. Between the poles of this magnet is an iron tube, surrounded by sittings. copper tube, to which a rapid rotary motion is imparted. The ...cts of induction tend to attract the magnet in the direction of the ...ry motion, and it is necessary, in order to maintain equilibrium, ...unterbalance this action by the aid of a counterpoise,* suspended at the extremity of a horizontal lever, perpendicular to the common axis of the magnet, and the revolving copper and iron tube.

Knowing the speed of rotation and the couple which equalises the inductive action, it is very easy to deduce therefrom the inductive energy absorbed by the system, energy which is transformed entirely into heat.

To obtain a constant speed, the copper and iron tube is set in motion by means of an electro-motor provided with a centrifugal interrupter, invented by M. Marcel Deprez. We can thus, and this is the preferable means, utilise the tendency to displacement of the magnet, under the influence of feeble variations of speed, to break or close the circuit of the electric motor which actuates the apparatus. The speed varies then only to a very small degree. The speed-indicator is therefore transformed into a Foucault disc, with a constant speed and of a peculiar form, in which the quantity of inductive energy, transformed into heat, is measured very exactly by means of the speed of rotation, and of the couple which equalises the magnet. It is important to observe that this method eliminates all passive resistances, only taking account of the inductive energy transformed into heat in the copper and iron tube. It remains now to measure the quantity of heat given out in the system in rotation.

To this end M. Marcel Deprez applies the principle of the sulphurous acid calorimeter of M. d'Arsonval. The apparatus designed for measurement comprises a movable magnet and a fixed copper and iron tube, that is to say, an arrangement the reverse of that for the speed-indicator. The interior of the fixed tube, closed at both extremities, is filled with sulphurous acid in communication by a small tube with an external reservoir. The evaporation of the sulphurous acid and its condensation in the external tube are effected by the most slight elevation of temperature. The volume of acid condensed in a given time indicates the number of calories furnished by the apparatus. Condensation occurring at the temperature of the surrounding air, there is no correction to make in this respect. In order that the feeble elevation of temperature of the tube of copper and iron may not produce any radiation and any loss of heat, this tube is enveloped in swan's down, which opposes radiation.

The tube being fixed and the magnet movable, the tube tends to be attracted by the magnet. The torsion couple is equalised by a platinum wire, the effect of which is measured, applying the laws of elasticity.



APPARATUS FOR MEASURING THE MECHANICAL EQUIVALENT OF HEAT.—MARCEL DEPREZ.

A, B. Ends of the revolving magnet.
E. Tube of iron. F. Tube of copper.
H. Envelope of swan's down.
R. Interior of tube enclosing sulphurous acid.
T. Tube of communication.
S. Sulphurous acid condensing chamber.

We have thus, on one hand, the exact measurement of inductive energy, and on the other hand the measurement of the heat liberated by this inductive energy. He deduces from it directly the value of the mechanical equivalent of heat, writing that the inductive energy in a given time, when the *régime* is established, is equal to the heat evolved deducted from the quantity of sulphurous acid condensed during the same time, multiplied by the mechanical equivalent of heat, the only unknown quantity in the problem. The apparatus is constructed with great accuracy, and gives the hope of determining the mechanical equivalent of heat as near as 1-1000 owing to the ingenious method of which M. Marcel Deprez has just presented the principle to the association.

SITTING OF THE 28TH AUGUST, 1882.

ELECTRICAL INCANDESCENT LAMPS ACTING IN THE OPEN AIR.

BY M. EMILE REYNIER.

The process of incandescence in the open air, which I made known in 1878, is now abandoned. Various causes brought

The associati ...e speed-indicator properly so called, the magnet, which has been properly ...nclined at a certain angle dependent on this speed, and it is this angle devoted to mathe ...mits of its determination.

this about; not to mention those of a technical order. I recognise that my old lamps have a rather low photometric effect; that certain of their parts are delicate, and call for attentions sometimes incompatible with the requirements of practice.

FIG. 1.

But these defects, connected with one system of lamp, and to the dispositions which have been given to it, are not inherent to the process of incandescence in the open air itself. I was therefore able to seek, with the same view, new systems, giving, like the old one, a white and fixed light, and in which the defects recognised in the old lamps will be eliminated or decreased. It is the results of these new researches which I wish to explain clearly.

I shall only illustrate by figures the principle of my old system (fig. 1) and its most usual form (fig. 2), to bring immediately to the fore the description of the unpublished details.

Second System.

With a given electric conductor, one can considerably increase its resistance by cutting it transversely in various places. The increase

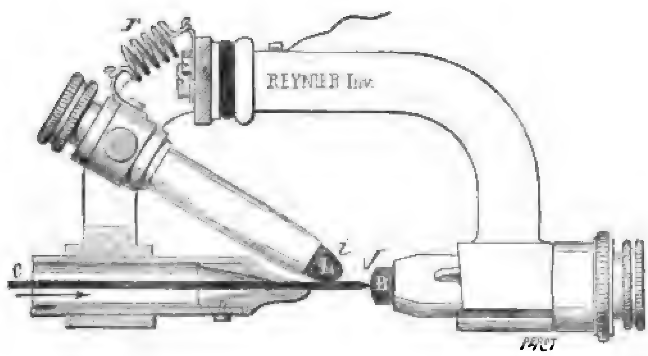


FIG. 2.

of resistance is more considerable in proportion as the sections are more numerous and smaller.

Fig. 3 shows a conductor of graphite composed of a certain number of superposed layers, moderately pressed together between two contacts.

FIG. 3.

FIG. 4.

Such a conductor, mounted in a transparent, hollow, and completely closed receptacle, would constitute a good electric lamp; but its construction gives rise to difficulties which have not been overcome.

In air the combustion of the incandescent carbon necessitates the renewal of the material of the luminous matter. This is how the difficulty may be surmounted.

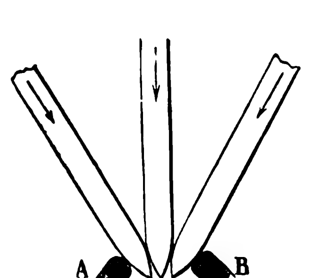

FIG. 5.

The dissected conductor is composed of the converging extremities of small rods of carbon, which come together between the two contacts, A and B (fig. 4), each rod is traversed, transversely and at its extremity only, by the electric current. With n carbons, one obtains $n + 1$ contacts. The renewal of the carbon as consumed is brought about by the continual progression of the carbons, which coincide, like the *voussoirs* of an arch, of which the contact pieces will be the piers.

The arrangement indicated in fig. 4 is only realisable with very thin carbons in the transverse direction; carbons of round or square section take a wolf's tooth form (fig. 5), which is unfavourable to the luminous effect of the apparatus, for the points relatively cold which stand out from the dissected conductor are the seat of a very important superfluous emission of heat.

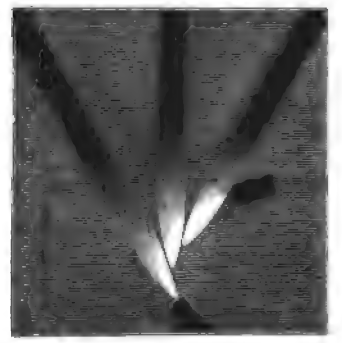

FIG. 6.

We have overcome this difficulty in the arrangement, fig. 6. The dissected conductor describes a broken line, and the current, traversing the end of each rod obliquely, leaves no point out of circuit. Fig. 7 represents an electric lamp constructed upon this principle. The carbons, guided between two pumice-stone plates, are respectively propelled towards the opening of the lamp by unequal weights, sliding in grooves made in a brass triangle. The insulated pieces, A and B, serve as stops and as terminal contacts.

This lamp acts well, but we must wait, to judge of it, until it is provided with carbons of a very

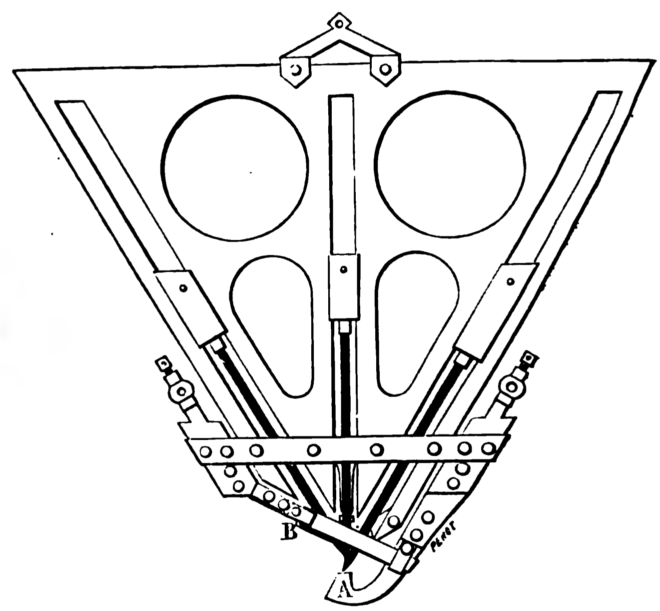

FIG. 7.

flattened section, which will allow of multiplication and of approximating the contacts, to simplify the lamp and diminish its size.

Provisionally, I prefer the following recent invention, which is more simple, less voluminous, and acting with any carbons whatever.

Third System.

I utilise here the thin form which we notice in the two preceding systems.

There are two rods of carbon made thinner at one end (fig 8); they are placed in the same plane, almost parallel to each other, and are approximated until they touch; their point of contact, x, will be

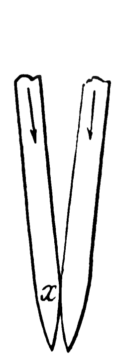

FIG. 8.

FIG. 9.

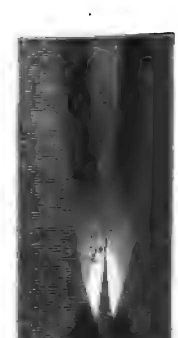

FIG. 10.

situated above the points, towards the base of the coning. The points being free, one can make them rest upon two contacts, A and B (fig. 9), and thus obtain an incandescent system in which the electric current

traverses successively, in the opposite direction, the two pointed ends, passing from one to the other by their lateral mutual contact.

To maintain the parts in this condition, notwithstanding the combustion of the points, it is necessary continuously to impel the carbons, in a longitudinal direction, and to give to the supporting contacts a suitable obliquity (fig. 10); the rods ought also to be guided in their common plane. Under these conditions, the pointed form is maintained; the carbons continue to impinge upon their respective contacts, and to touch each other at a certain distance above the points. Fig. 11 represents one practical form given to the apparatus. The carbons, A and B, are respectively impelled by weights, P and Q, sliding upon two metallic guides, C and D. The oblique contacts, E, F, are two sheets of copper, fixed upon bronze arcs, G, H. Two pairs of insulated clamps, I and J, connect the two halves of the lamp; the first pair is of wood, the second is of slate, and forms a slot, which guides the two carbons in their common plane.

The weights, P and Q, are insulated from the carbons which they impel, by ivory caps, *r* and *s*.

The electric current, entering by the terminal, K, follows the brass guide, C, the bend, G, the contact, E, goes up the pointed extremity of the carbon, A, passes over the contact, *x*, descends by the carbon end, B, and follows the contact, F, the bend, H, and the guide, D, to the terminal, L.

The two extreme contacts make little shadow; the middle contact causes no loss of heat or light, and usefully increases the total resistance of the lamp.

This combination of two very approximate incandescent points, and of three neighbouring contacts, procures a concentration of heat favourable to the photometric effect of the apparatus.

The experiments in progress will give, on this point, figures which will confirm the favourable impression produced by the first trials.

The apparatus is simple, easily manipulated, and of certain action; its narrow and symmetrical form allows of using it everywhere.

As to the necessity of renewing the carbons daily, it has been necessary, up to this day, to submit to it in all systems capable of giving *white* light with a good photometric effect.

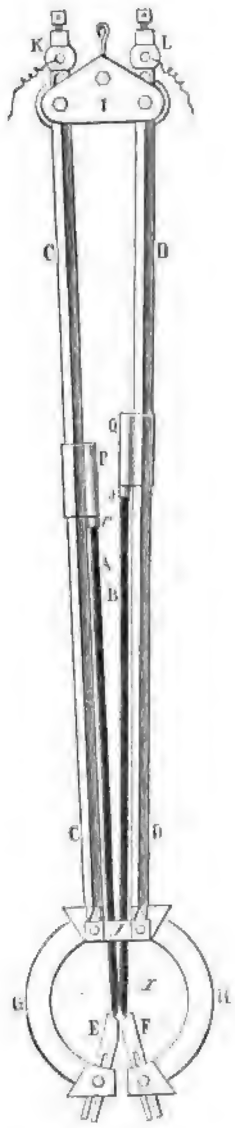

FIG. 11.

The most grave defect of my incandescent lamps is their too feeble resistance, which necessitates the employment of intense currents, the transmission of which is costly.

From this point of view, the third system, is superior to the first, but inferior to the second.

A DIFFERENTIAL ELECTRIC THERMOSCOPE.

By W. F. NOSWORTHY.

IT has of late frequently been pointed out to students and others that little real progress can be made in any branch of science from the cursory reading of a book; that by experiment alone can such subjects be successfully grappled with.

This is undoubtedly true; but it must be remembered that by far the greater portion of such persons are unable to attend lectures, join societies, or otherwise avail themselves of the facilities offered to those who have the good fortune to reside in London or other large city where these institutions exist, while the excessive cost of scientific apparatus, even of the most elementary nature (frequently exceeding many times the intrinsic value of the articles), forbids their procuring the necessary instruments wherewith to experiment at home.

This latter fact is undeniably a great obstacle to the progress of science, therefore whatever steps are taken tending to reduce the price of scientific apparatus generally will, I venture to say, be welcomed by all, and prove a material aid to science by increasing the number of workers in the field.

To persons engaged in the study of radiant heat, or even those who have occasionally to measure small differences of temperature, the possession of a thermopile is of paramount importance. The cost of this instrument is about £4 4s.

The object of the present communication is to call the attention of those interested to a simple arrangement which may with advantage replace the thermopile, and be constructed by any one at a cost not exceeding five shillings.

It has long been known that the electrical resistance of a wire varies with every change of temperature, the resistance increasing with a rise and diminishing with a fall of temperature. This fact forms the principle upon which the instrument about to be described is based.

Four coils of fine, silk-covered copper wire are joined up with a delicate galvanometer and a couple of Daniell's cells as a Wheatstone's bridge (fig. 1). If the resistances of the

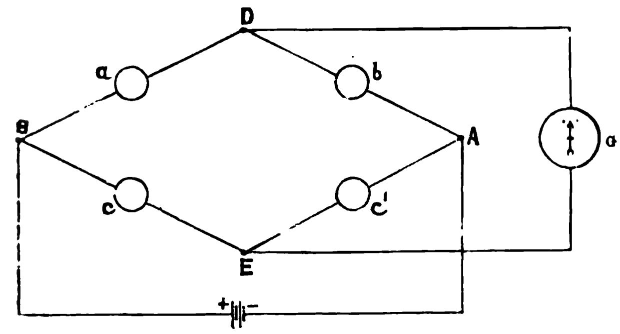

FIG. 1.

coils, *a*, *b*, c, c′, are equal and at the same temperature, the points, D and E, will be at the same potential; therefore no current will flow through the galvanometer, G.

Suppose, now, the temperature of one of the coils, c, for example, be raised, the resistance of that coil will be increased and the potential of the point, E, thereby reduced relatively

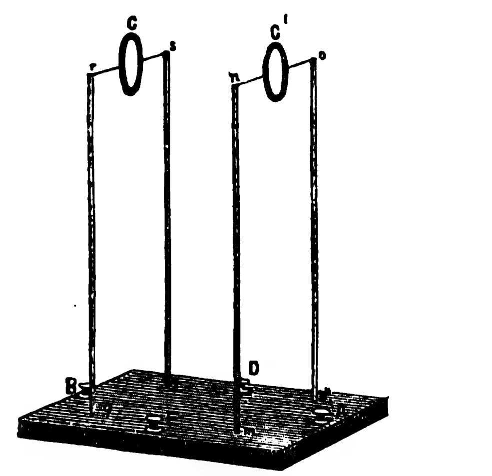

FIG. 2.

to that of D, consequently a current will flow through G in the direction from D to E, causing a deflection, say, to the left. On the other hand, if it be the temperature of c′ that is increased the potential of E will be raised above that of D, and the direction of the current through G reversed, the deflection in this case being to the right. If however the temperature of both c and c′ be increased or reduced by exactly equal amounts, no change will take place in the potential at E, and there will be no deflection of the galvanometer.

From what has now been stated fig. 2 will be readily understood.

The two coils, *a*, *b* (fig. 1), are embedded in the base of the instrument, while the coils, c, c′, are supported, as shown, by the four glass tubes, *m n*, *o p*, *q r*, *s t*, through which the connecting wires from the respective coils pass to the terminals on the base. The battery may be connected to the terminals, B, A, and the galvanometer to D, E, or *vice versâ*. Arranged thus, the instrument forms a differential thermoscope of great sensibility, and can be used in every case where the thermopile has hitherto been employed.

In the instrument represented by the drawing the four coils are composed of No. 40 silk-covered copper wire and

have a resistance of 20 B.A. units each. The coils, c, c′, are further coated with lampblack. The galvanometer used in connection therewith is an astatic mirror, of which a section having a resistance of 125 ohms has been employed.

It will be seen that the relation between the resistance of the galvanometer and coils is not such as to give the maximum sensibility to the arrangement, nevertheless the comparisons made between this instrument and a thermopile of forty-eight pairs of antimony-bismuth plates, having a resistance of 1·4 units, and joined up with an astatic reflecting galvanometer of 1·5 units resistance, specially constructed for use with the pile, are extremely satisfactory, for when a source of heat is placed equidistant from the two the galvanometer in connection with the thermoscope invariably gives the highest deflection, and is also the first to sink to zero when the source of heat is removed.

For those who have not the means of measuring the resistance, the coils may be made of equal lengths of wire. As, however, owing probably to mechanical defects in manufacture, two equal lengths of the same wire seldom have exactly the same resistance, it will be necessary to finally adjust the coils by adding or cutting off a small piece of the wire until the galvanometer shows no movement when the battery circuit is closed. Sufficient time should elapse between touching the coils and making this trial to allow the wire to assume the temperature of the atmosphere, otherwise the coil last touched will appear to have the greatest resistance.

Many improvements in the construction of the instrument will readily suggest themselves, the form shown in the figure has, however, answered all my requirements, indeed since its completion I have seldom used the thermopile.

CHASTER'S TELEPHONIC APPARATUS.

THIS arrangement, which is shown in general appearance by fig. 1, is the invention of Mr. J. E. Chaster. It is a very convenient and neat adaptation of an electro-magnetic telephone with a microphonic transmitter.

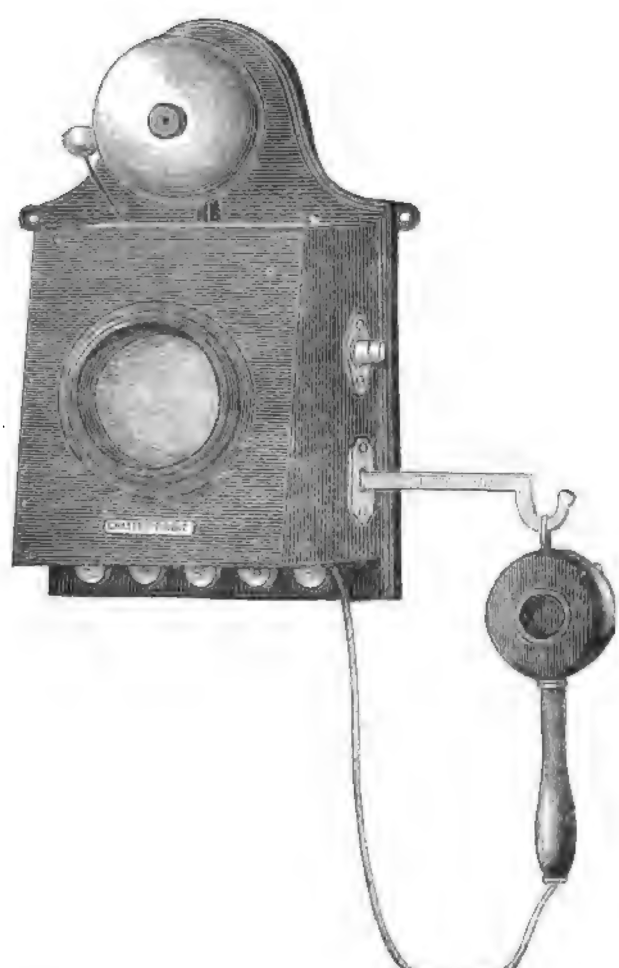

FIG. 1.

The receiver of this apparatus (the essential portion of which is shown in section by fig. 2) will be readily understood by those conversant with telephonic matters. The metal case in which the electro-magnetic coil is enclosed is of iron, and practically forms a prolongation of the lower pole of the electro-magnet. The edges of the ferrotype diaphragm rest on the edge of the metal box, and are secured by means of a screw cap. The magnetisation of the electro-magnet is effected by means of the line current, there being no induction-coil in the apparatus.

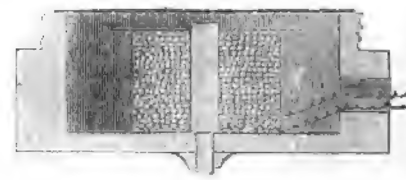

FIG. 2.

The microphonic transmitter, which is a feature in the apparatus, can be seen in fig. 3. It is formed of four vertical carbon pencils connected up in sets of two, the current passing down one set and up the other, as can be seen. The microphones are set on a thin board, which is hinged at the top, and which is kept pressed gently forward against its frame by means of a lead weight. The front surface of the board is opposite a round orifice (seen in fig. 1), into which the operator speaks. We may mention in conclusion that the four upright pieces of carbon-pencil belonging to the microphone transmitter are each wrapped round their middles with a band of sheet lead for the purpose of increasing their weight.

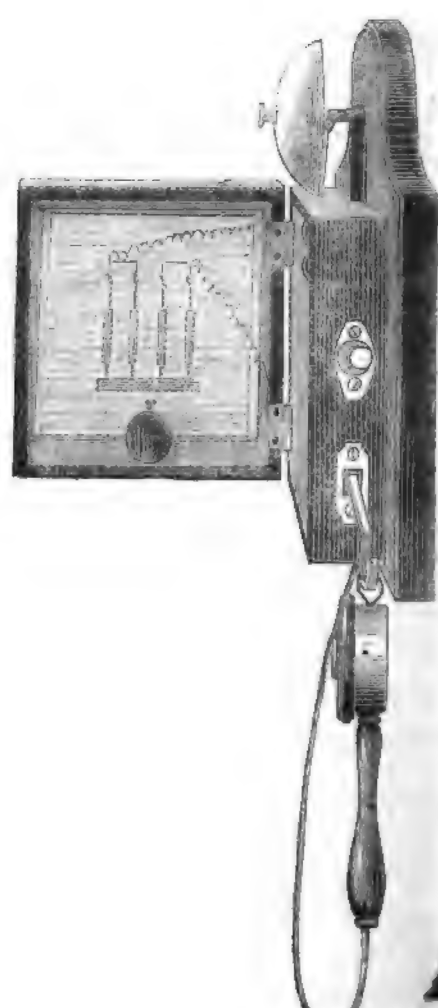

FIG. 3.

The apparatus is provided with the usual switch lever, alarum bell, and push button.

REPORT OF ELECTRICAL TESTS OF THE "1881" AND "1882" ATLANTIC CABLES OF THE AMERICAN TELEGRAPH AND CABLE COMPANY.

Taken at Penzance on the 1st and 2nd July, 1882.

SIEMENS BROTHERS & CO.'S TELEGRAPH WORKS,
MESSRS. SIEMENS BROS. & CO., Charlton Pier, Woolwich, Kent.
12, Queen Anne's Gate, Westminster. *July 27th*, 1882.

DEAR SIRS,—In accordance with your instructions, I proceeded to Penzance for the purpose of testing the "1881" and "1882" cables of the American Telegraph and Cable Company, to which end every facility was afforded me by the Company's Superintendent there, Mr. Mockridge. On the evening of the 1st instant, I tested the "1881" and "1882" cables separately, and on the 2nd instant, took a series of tests of both cables together, their ends being joined at Canso. I enclose a detailed description of the methods employed, the observations recorded, and the results deduced therefrom. I was fortunate in finding the cables remarkably free from disturbance by earth currents during the whole time I tested, and the results obtained are therefore the more accordant, and, as you will gather from inspection of the results, highly satisfactory, and evidencing both cables to be in perfect electrical condition.

I am, dear Sirs, yours faithfully,
FRANK JACOB, M.S.T.E., M.P.S. Lond., &c.

METHODS OF TESTING.

CONDUCTOR RESISTANCE.

This was determined by "reproduced deflection" as follows:—

The cable, with its distant end to earth, is connected through a suitably shunted galvanometer and battery with reversing key to earth, and a series of deflections (the battery being reversed between each reading) are taken as rapidly as possible and recorded; a resistance box is then substituted in place of the cable, and varied until the same deflections are reproduced; the resistances thus obtained are equal to the apparent resistances offered by the cable to either current. The harmonic mean of the results, with positive and negative current to line respectively, gives the true resistance of the conductor. The advantage gained by this over the usual "bridge" method is, that reversals can be taken far more rapidly, and the variation caused by earth currents, as well as being continuously under observation, be most easily eliminated; and if an "inferred zero" be used, by having the spot, when no current is passing through the galvanometer coils, considerably off the scale, the results can be determined to the same degree of accuracy as in the method referred to above.

ELECTRO-STATIC CAPACITY.

This was determined by the "Balance" method, as described by Sir W. Thomson in his Report of Testing the Direct United States Cable Company's cable, on the 16th and 17th December, 1875.

DIELECTRIC RESISTANCE.

This, as the earth currents were found to be remarkably steady, was measured in the ordinary way by the "deflection" method.

A battery of 40 Daniell's elements in series was used for all the tests.

Length of Cables from Sennen (Cornwall) to Dover Bay (Nova Scotia):

"1881" cable .. .. .. 2517·76 nautical miles.
"1882" cable .. .. .. 2562·70 ,, ,,

At the Cornwall end there is a quadruple underground cable laid to Penzance, the resistance of each core being 19·5 Siemens units, and electro-static capacity 3·1 microfarads. On the Nova-Scotian side four underground cables connect to Canso, having each a resistance of 15·5 Siemens units, and a capacity of 2·5 microfarads. The dielectric resistance of these may be neglected, in comparison with that of the submarine cables, without introducing any perceptible error.

Earth is obtained for each cable by one of the underground cables, which is connected at the landing place by well-soldered and massive joints to the sheathing wires of each shore-end cable respectively.

ELECTRICAL TESTS OF THE "1881" CABLE.

From 8.15 to 8.25 p.m., on July 1st, this cable was earthed and then insulated until 9.15 p.m. at Canso.

CONDUCTOR RESISTANCE.

Negative current to line 8,570 S.U. } harmonic mean =
Positive ,, ,, 7,650 S.U. } 8,084 Siemens units.

Subtracting 70 S.U. for the resistance of the underground cables at each side, we obtain 8,014 Siemens units as the resistance of the submarine cable, or a mean, per nautical mile, of 3·184 Siemens units.

ELECTRO-STATIC CAPACITY.

Negative current to line 904·9 mfds. } mean = 892·6
Positive ,, ,, 880·3 ,, } microfarads.

Subtracting 5·6 microfarads for that of the underground cables, we obtain 887 microfarads as the capacity for the submarine cable, or a mean of 0·352 microfarad per nautical mile.

DIELECTRIC RESISTANCE.

The "constant" of the galvanometer or the resistance which with infinite resistance in the shunt would give a deflection of one division, was 19,700 millions Siemens units, and the deflections through the cable were taken with a shunt having one-ninth of the galvanometer's resistance.

The results are exhibited in tabular form.

Column I. gives the time of electrification;
,, II. ,, the mean deflection observed each minute;
,, III. ,, the resistance calculated from "II.";
,, IV. ,, these resistances reduced for electrification to the value for the first minute's electrification, so as to obtain the mean first minute result from the ten minutes' test.

POSITIVE CURRENT TO LINE.

I. Minutes.	II. Deflection.	III. Millions Siemens units.	IV. Millions Siemens units.	
1	320	6·16	6·2	
2	230	8·56	7·1	
3	300	6·57	5·1	
4	230	8·56	6·3	Mean of results reduced to electrification after first minute = 8·3 millions Siemens units, or 20,900 millions Siemens units per nautical mile.
5	100	19·70	[14·2]*	
6	180	10·95	7·6	
7	150	13·14	8·9	
8	120	16·42	10·9	
9	120	16·42	10·6	
10	100	19·70	11·9	

NEGATIVE CURRENT TO LINE.

I. Minutes.	II. Deflection.	III. Millions Siemens units.	IV. Millions Siemens units.	
1	410	4·80	4·8	
2	330	5·97	4·9	
3	200	9·85	7·6	
4	100	19·70	14·6	Mean of results reduced to electrification after first minute = 7·4 millions Siemens units, or 18,640 millions Siemens units per nautical mile.
5	50	39·40	[28·3]*	
6	180	10·95	7·6	
7	180	10·95	7·4	
8	200	9·85	6·5	
9	200	9·85	6·3	
10	170	11·59	7·3	

The cable was earthed for ten minutes between the tests with the two currents.

Mean of results with both currents to line, reduced to electrification after first minute:

7·85 millions Siemens units for the whole cable, or 19,770 millions Siemens units per nautical mile.

ELECTRICAL TESTS OF THE "1882" CABLE.

Earthed at Canso 9.15 to 9.25 p.m., and insulated till 10.15 p.m.

CONDUCTOR RESISTANCE.

Negative current to line 8,334 S.U. } Mean:
Positive ,, ,, 8,334 ,, } 8,334 Siemens units.

No difference between the results with each current, thus evidencing the smallness of the earth currents. Subtracting 70 Siemens units for the resistance of the underground cables, this gives 8,264 Siemens units for the resistance of the submarine cable, or a mean, per nautical mile, of 3·225 Siemens units.

ELECTRO-STATIC CAPACITY.

The same with both currents to line, viz., 930·6 microfarads. Subtracting 5·6 microfarads for the underground cables, the submarine cable has a capacity of 925 microfarads, or a mean of 0·361 microfarad per nautical mile.

DIELECTRIC RESISTANCE.—POSITIVE CURRENT TO LINE.

I. Minutes.	II. Deflection.	III. Millions Siemens units.	IV. Millions Siemens units.	
1	320	6·16	6·2	
2	270	7·30	6·1	
3	260	7·58	5·9	
4	250	7·88	5·8	Mean of results reduced to electrification after first minute = 7·0 millions Siemens units, or 17,940 millions Siemens units per nautical mile.
5	220	8·95	6·4	
6	210	9·39	6·5	
7	170	11·59	7·8	
8	160	12·31	8·1	
9	160	12·31	7·9	
10	140	14·07	8·9	

* The figures in brackets are excluded, being due to a variation in earth currents.

NEGATIVE CURRENT TO LINE.

I. Minutes.	II. Deflection.	III. Millions Siemens units.	IV. Millions Siemens units.	
1	320	6·16	6·1	
2	170	11·59	9·6	
3	170	11·59	9·0	
4	220	8·95	6·6	Mean of results reduced to electrification after first minute = 7·8 millions Siemens units, or 20,000 millions Siemens units per nautical mile.
5	170	11·59	8·3	
6	150	13·14	9·1	
7	180	10·95	7·4	
8	100	19·70	[13·0]*	
9	220	8·95	5·8	
10	150	13·14	8·3	

The cable was earthed for ten minutes between each series.

Mean of results with both currents to line, reduced to electrification after first minute,

= 7·4 Siemens units for the whole cable, or 18,970 millions Siemens units per nautical mile.

ELECTRICAL TESTS OF THE "1881" AND "1882" CABLES JOINED.

July 2nd, 8.15 a.m., both cables were joined at Canso.

CONDUCTOR RESISTANCE.

Measured by the "bridge" method.

$\left.\begin{array}{l} -\ 16{,}409 \text{ Siemens units} \\ +\ 16{,}284 \text{ Siemens units} \end{array}\right\}$ mean = 16346·5 Siemens units.

Subtracting 70 Siemens units for the resistance of the underground cables at each end, gives:

16276·5 Siemens units for the sum of the resistance of the two cables, which agrees very closely with the sum of the resistances of the two cables taken separately the day before, viz., 16,278 Siemens units.

DIELECTRIC RESISTANCE.

The deflections were taken with a shunt having a resistance 1-99th of that of the galvanometer, and the "constant" was 19,600 millions Siemens units.

For these two series the ends of both cables were connected at Penzance, and thus the circuit was charged simultaneously from both ends.

NEGATIVE CURRENT TO LINE.

I. Minutes.	II. Deflection.	III. Millions Siemens units.	IV. Millions Siemens units.	
1	70	2·80	2·80	
2	58	3·38	2·82	
3	32	6·12	4·74	
4	55	3·56	2·64	Mean reduced to electrification after first minute = 3·945 millions Siemens units, or 20,040 millions Siemens units per nautical mile.
5	20	9·80	7·05	
6	60	3·26	2·27	
7	25	7·84	5·30	
8	35	5·60	3·71	
9	40	4·90	3·16	
10	25	7·84	4·96	

Cable earthed for ten minutes, then

POSITIVE CURRENT TO LINE.

I. Minutes.	II. Deflection.	III. Millions Siemens units.	IV. Millions Siemens units.	
1	90	2·18	2·18	
2	60	3·26	2·72	
3	47	4·17	3·23	
4	35	5·60	4·15	Mean reduced to electrification after first minute = 3·961 millions Siemens units, or 20,120 millions Siemens units per nautical mile.
5	35	5·60	4·03	
6	20	9·80	6·80	
7	40	4·90	3·31	
8	20	9·80	6·49	
9	40	4·90	3·16	
10	35	5·60	3·54	

The cable was again earthed for fifteen minutes, and then the following series taken by charging the end of the "1881" cable and leaving the end of the "1882" cable insulated free in air at Penzance. It will be noticed that the first three minutes' readings give higher deflections than in the former series; this is due to the length of cable now existing between the charging battery and the distant end, which is insulated, thus increasing the time required for the cable to arrive at a uniform tension throughout.

* The figures in brackets are excluded, being due to a variation in earth currents.

NEGATIVE CURRENT TO LINE.

I. Minutes.	II. Deflection.	III. Millions Siemens units.	IV. Millions Siemens units.	
1	190	1·03	1·03	
2	75	2·61	2·18	
3	50	3·92	3·04	
4	45	4·36	3·23	Mean of results reduced to electrification after first minute = 4·25 millions Siemens units, or 21,600 millions Siemens units per nautical mile.
5	30	6·53	4·70	
6	20	9·80	6·80	
7	20	9·80	6·62	
8	20	9·80	6·49	
9	30	6·53	4·21	
10	15	13·06	[8·26]*	

The cable was then earthed for ten minutes, and the following series taken, with the end of the "1882" cable charged, and the end of the "1881" cable insulated free in air at Penzance.

POSITIVE CURRENT TO LINE.

I. Minutes.	II. Deflection.	III. Millions Siemens units.	IV. Millions Siemens units.	
1	200	0·98	0·98	
2	75	2·61	2·18	
3	60	3·27	2·53	
4	30	6·53	4·84	Mean of results reduced to electrification after first minute = 3·95 millions Siemens units, or 20,070 millions Siemens units per nautical mile.
5	30	6·53	4·70	
6	10	19·60	[13·61]*	
7	30	6·53	4·41	
8	25	7·84	5·19	
9	30	6·53	4·21	
10	20	9·80	6·20	

The mean of the four series of tests of the two cables joined at Canso gives a result for the first minute's electrification of 4·026 millions Siemens units, or 20,450 millions Siemens units per nautical mile.

Appended is a summary of the tests of the two cables since completion of laying up to date, as well as of the results obtained from the sum of the tests of the separate coils composing each cable, which were taken at the works during the manufacture of the cable at the two fixed temperatures of 75° and 50° Fahrenheit.

SUMMARY OF RESULTS OF ELECTRICAL TESTS OF THE "1881" AND "1882" ATLANTIC CABLES.

THE BRITISH ASSOCIATION.

[*Specially reported for the* ELECTRICAL REVIEW.]

ADDRESS TO THE MATHEMATICAL AND PHYSICAL SCIENCE SECTION.

By LORD RAYLEIGH, M.A., F.R.S., F.R.A.S.

IN common with some of my predecessors in this chair, I recognise that probably the most useful form which a presidential address could take would be a summary of the progress of physics, or of some important branch of physics, during recent years. But the difficulties of such a task are considerable, and I do not feel myself equal to grappling with them. The few remarks which I have to offer are of a general—I fear it may be thought of a commonplace—character. All I can hope is that they may have the effect of leading us into a frame of mind suitable for the work that lies before us.

The diversity of the subjects which come under our notice in this section, as well as of the methods by which alone they can be adequately dealt with, although a sign of the importance of our work is a source of considerable difficulty in the conduct of it. From the almost inevitable specialisation of modern science, it has come about that much that is familiar to one member of our section is unintelligible to another, and that details whose importance is obvious to the one fail altogether to rouse any interest in the mind of the other. I must appeal to the authors of papers to bear this difficulty in mind, and to confine within moderate limits their discussion of points of less general interest.

Even within the limits of those departments whose foundation is evidently experimental, there is room, and indeed necessity, for great variety of treatment. One class of investigators relies mainly upon reiterated appeals to experiment to resolve the questions which appear still to be open, while another prefers, with Thomas Young, to base its decisions as far as possible upon deductions from experiments already made by others. It is scarcely necessary to say that in the present state of science both methods are indispensable. Even where we may fairly suppose that the fundamental principles are well established, careful and often troublesome work is necessary to determine with accuracy the constants which enter into the expression of natural laws. In many cases the accuracy desirable, even from a practical point of view, is hard to attain. In many others, where the interest is mainly theoretical, we cannot afford to neglect the confirmations which our views may derive from the comparison of measurements made in different fields, and in face of different experimental difficulties. Examples of the inter-dependence of measurements apparently distinct will occur to every physicist. I may mention the absolute determinations of electrical resistance, and of the amounts of heat developed from electrical and mechanical work, any two of which involve also the third, and the relation of the velocity of sound to the mechanical and thermal properties of air.

Where a measurement is isolated, and not likely to lead to the solution of any open question, it is doubtless possible to spend upon it time and attention that might with advantage be otherwise bestowed. In such a case we may properly be satisfied for a time with work of a less severe and accurate character, knowing that with the progress of knowledge the way is sure to be smoothed both by a better appreciation of the difficulties involved and by the invention of improved experimental appliances. I hope I shall not be misunderstood as underrating the importance of great accuracy in its proper place if I express the opinion that the desire for it has sometimes had a prejudicial effect. In cases where a rough result would have sufficed for all immediate purposes, no measurement at all has been attempted, because the circumstances rendered it unlikely that a high standard of precision could be attained. Whether our aim be more or less ambitious, it is important to recognise the limitations to which our methods are necessarily subject, and as far as possible to estimate the extent to which our results are uncertain. The comparison of estimates of uncertainty made before and after the execution of a set of measurements may sometimes be humiliating, but it is always instructive.

Even when our results show no greater discrepancies than we were originally prepared for, it is well to err on the side of modesty in estimating their trustworthiness. The history of science teaches only too plainly the lesson that no single method is absolutely to be relied upon, that sources of error lurk where they are least expected, and that they may escape the notice of the most experienced and conscientious worker. It is only by the concurrence of evidence of various kinds and from various sources that practical certainty may at last be attained, and complete confidence justified. Perhaps I may be allowed to illustrate my meaning by reference to a subject which has engaged a good deal of my attention for the last two years—the absolute measurement of electrical resistance. The unit commonly employed in this country is founded upon experiments made about twenty years ago by a distinguished committee of this association, and was intended to represent an absolute resistance of 10^9 C.G.S.—*i.e.*, one ohm. The method employed by the committee at the recommendation of Sir W. Thomson (it had been originally proposed by Weber) consisted in observing the deflection from the magnetic meridian of a needle suspended at the centre of a coil of insulated wire, which formed a closed circuit, and was made to revolve with uniform and known speed about a vertical axis. From the speed and deflection in combination with the mean radius of the coil and the number of its turns, the absolute resistance of the coil, and thence of any other standard, can be determined.

About ten years later Kohlrausch attacked the problem by another method, which it would take too long to explain, and arrived at the result that the B.A. unit was equal to 1·02 ohms—about 2 per cent. too large. Rowland, in America, by a comparison between the steady battery current flowing in a primary coil with the transient current developed in a secondary coil when the primary current is reversed, found that the B.A. unit was ·991 ohms. Lorentz, using a different method again, found ·980, while H. Weber, from distinct experiments, arrived at the conclusion that the B.A. unit was correct. It will be seen that the results obtained by these highly competent observers range over about 4 per cent. Two new determinations have lately been made in the Cavendish laboratory at Cambridge, one by myself with the method of the revolving coil, and another by Mr. Glazebrook, who used a modification of the method followed by Rowland, with the result that the B.A. unit is ·986 ohms. I am now engaged upon a third determination, using a method which is a modification of that of Lorentz.

In another important part of the field of experimental science, where the subject-matter is ill understood, and the work is qualitative rather than quantitative, success depends more directly upon sagacity and genius. It must be admitted that much labour spent in this kind of work is ill-directed. Bulky records of crude and uninterpreted observations are not science, nor even in many cases the raw material out of which science will be constructed. The door of experiment stands always open; and when the question is ripe, and the man is found, he will nine times out of ten find it necessary to go through the work again. Observations made by the way, and under unfavourable conditions, may often give rise to valuable suggestions, but these must be tested by experiment, in which the conditions are simplified to the utmost, before they can lay claim to acceptance.

When an unexpected effect is observed, the question will arise whether or not an explanation can be found upon admitted principles. Sometimes the answer can be quickly given; but more often it will happen that an assertion of what *ought* to have been expected can only be made as the result of an elaborate discussion of the circumstances of the case, and this discussion must generally be mathematical in its spirit, if not in its form. In repeating, at the beginning of the century, the well-known experiment of the inaudibility of a bell rung in vacuo, Leslie made the interesting observation that the presence of hydrogen was inimical to the production of sound, so that not merely was the sound less in hydrogen than in air of equal pressure, but that the actual addition of hydrogen to rarefied air caused a diminution in the intensity of sound. How is this remarkable fact to be explained? Does it prove that, as Herschel was inclined to think, a mixture of gases of widely different densities differs in its acoustical properties from a single gas? These questions could scarcely be answered satisfactorily but by a mathematical investigation of the process by which vibrations are communicated from a vibrating solid body to the surrounding gas. Such an investigation, founded exclusively upon principles well established before the date of Leslie's observation, was undertaken years afterwards by Stokes, who proved that what Leslie observed was exactly what ought to have been expected. The addition of hydrogen to attenuated air increases the wave-length of vibrations of given pitch, and consequently the facility with which the gas can pass round the edge of the bell from the advancing to the retreating face, and thus escape those rarefactions and condensations which are essential to the formation of a complete sound wave. There remains no reason for supposing that the phenomenon depends upon any other elements than the density and pressure of the gaseous atmosphere, and a direct trial, *e.g.*, a comparison between air and a mixture of carbonic anhydride and hydrogen of like density, is almost superfluous.

Examples such as this, which might be multiplied *ad libitum*, show how difficult it often is for an experimenter rightly to interpret his results without the aid of mathematics. It is eminently desirable that the experimenter himself should be in a position to make the calculations, to which his work gives occasion, and from which in return he would often receive valuable hints for further experiment. I should like to see a course of mathematical instruction arranged with especial reference to physics, within which those whose bent was plainly towards experiment might, more or less completely, confine themselves. Probably a year spent judiciously on such a course would do more to qualify the student for actual work than two or three years of the usual mathematical curriculum. On the other side it must be remembered that the human mind is limited, and that few can carry the weight of a complete mathematical armament without some repression of their energies in other directions. With many of us difficulty of remembering, if not want of time for acquiring, would impose an early limit. Here, as elsewhere, the natural advantages of a division of labour will assert themselves. Innate dexterity and facility in contrivance, backed by unflinching perseverance, may often conduct to successful discovery or invention a man who has little taste for speculation; and on the other hand the mathematician, endowed with genius and insight, may find a sufficient field for his energies in interpreting and systematising the work of others.

The different habits of mind of the two schools of physicists sometimes lead them to the adoption of antagonistic views on doubtful and difficult questions. The tendency of the purely experimental school is to rely almost exclusively upon direct evidence, even when it is obviously imperfect, and to disregard arguments which they stigmatise as theoretical. The tendency of the mathematician is to overrate the solidity of his theoretical structures, and to forget the narrowness of the experimental foundation upon which many of them rest.

By direct observation, one of the most experienced and successful experimenters of the last generation convinced himself that light of definite refrangibility was capable of further analysis by absorption. It has happened to myself, in the course of measurements of the absorbing power of various media for the different rays of the spectrum, to come across appearances at first sight strongly confirmatory of Brewster's views, and I can therefore understand the persistency with which he retained his opinion. But the possibility of further analysis of light of definite refrangibility (except by polarisation) is almost irreconcilable with the wave theory, which on the strongest grounds had been already accepted by most of Brewster's

contemporaries; and in consequence his results, though urgently pressed, failed to convince the scientific world. Further experiment has fully justified this scepticism, and in the hands of Airy, Helmholtz, and others, has shown that the phenomena by which Brewster was misled can be explained by the unrecognised intrusion of diffused light. The anomalies disappear when sufficient precaution is taken that the refrangibility of the light observed shall really be definite.

On similar grounds undulationists early arrived at the conviction that physically light and invisible radiant heat are both vibrations of the same kind, differing merely in wave-length; but this view appears to have been accepted slowly, and almost reluctantly, by the experimental school.

When the facts which appear to conflict with theory are well-defined and lend themselves easily to experiment and repetition, there ought to be no great delay in arriving at a judgment. Either the theory is upset, or the observations, if not altogether faulty, are found susceptible of another interpretation. The difficulty is greatest when the necessary conditions are uncertain, and their fulfilment rare and uncontrollable. In many such cases an attitude of reserve, in expectation of further evidence, is the only wise one. Premature judgments err perhaps as much on one side as on the other. Certainly in the past many extraordinary observations have met with an excessive incredulity. I may instance the fire-balls which sometimes occur during violent thunderstorms. When the telephone was first invented, the early reports of its performances were discredited by many on quite insufficient grounds.

It would be interesting, but too difficult and delicate a task, to enumerate and examine the various important questions which remain still undecided from the opposition of direct and indirect evidence. Merely as illustrations I will mention one or two in which I happen to have been interested. It has been sought to remedy the inconvenience caused by excessive reverberation of sound in cathedrals and other large unfurnished buildings by stretching wires overhead from one wall to another. In some cases no difference has been perceived, but in others it is thought that advantage has been gained. From a theoretical point of view it is difficult to believe that the wires could be of service. It is known that the vibrations of a wire do not communicate themselves in any appreciable degree directly to the air, but require the intervention of a sounding-board, from which we may infer that vibrations in the air would not readily communicate themselves to stretched wires. It seems more likely that the advantage supposed to have been gained in a few cases is imaginary than that the wires should really have played the part attributed to them.

The other subject on which, though with diffidence, I should like to make a remark or two, is that of Prout's law, according to which the atomic weights of the elements, or at any rate of many of them, stand in simple relation to that of hydrogen. Some chemists have reprobated strongly the importation of *à priori* views into the consideration of the question, and maintain that the only numbers worthy of recognition are the immediate results of experiment. Others, more impressed by the argument that the close approximations to simple numbers cannot be merely fortuitous, and more alive to the inevitable imperfections of our measurements, consider that the experimental evidence against the simple numbers is of a very slender character, balanced, if not outweighed, by the *à priori* argument in favour of simplicity. The subject is eminently one for further experiment; and as it is now engaging the attention of chemists, we may look forward to the settlement of the question by the present generation. The time has perhaps come when a redetermination of the densities of the principal gases may be desirable—an undertaking for which I have made some preparations.

If there is any truth in the views that I have been endeavouring to impress, our meetings in this section are amply justified. If the progress of science demands the comparison of evidence drawn from different sources, and fully appreciated only by minds of different order, what may we not gain from the opportunities here given for public discussion, and, perhaps more valuable still, private interchange of opinion? Let us endeavour, one and all, to turn them to the best account.

THE EDISON SYSTEM OF ELECTRIC DISTRIBUTION.

[Paper by F. J. Sprague, read at meeting of Section A of British Association, Friday, August 25th, 1882.]

I wish to speak of Mr. Edison's system as it has appeared to me after a thorough investigation and study of the same, extending over several months and with great facilities at my command, and my conclusions are based not on Mr. Edison's claims, or those of his friends, but as the result of a candid investigation. Mr. Edison's ambition has been far reaching, and he designs to establish a system of distribution, not alone for lighting, but for almost every purpose to which the electric current can be put: and he recognises the all-important principle that all parts of such a system are mutually dependent; that thorough mathematical and engineering talent must be used; that no detail is so unimportant, no real objection so trivial, but that it requires patient consideration; that dynamos, meters, lamps, motors, conductors, districts laid out, capital invested, and energy wasted, must all be calculated with reference to each other; in short, that economy and reliability are the great ends to be attained. The result is that he comes now before the world, after three years of hard work and patient experimenting, feeling fully equipped and able to establish thoroughly reliable and extensive installations. I have stated some of the requirements of a system of general distribution, and will consider that of Mr. Edison in detail and as a whole. I shall not give a full description of all the parts, but intend rather to consider it from a practical and economic point of view.

Dynamos.

These generators, which have armatures wound or connected on a modification of the Hefner-Alteneck system, may be divided into three classes.

1. Those having wire-wound armatures, the coils being wound on a wooden cylinder wrapped with a soft iron wire. These armatures are driven by belting, and rotate between the faces of long vertical magnets at a speed of 800 to 1,200 revolutions per minute, according to the size of machine and the number of lamps. By using a large mass of metal a powerful magnet may be created, rendering necessary a less number of convolutions of wire, and consequently less heat and waste in the armature for a given electromotive force. By using long magnets the mean resultant of the convolutions of wire is brought much nearer the centre of the core than would be the case with the same weight of metal and a shorter length. On account of this a more active magnetic field is produced, one with a greater projective power, and less current may be used in the field coils. This can be exemplified in a striking manner by reforging the cores with the same amount of iron, but making them shorter and rewinding with the same amount of wire as now used. With the same speed of armature and the same number of convolutions the electromotive force of the machine will fall very appreciably; and this lower electromotive force can be obtained by using the large magnets with the faces at a much greater distance from the surface of the armature. The commutator is long; its life or time of running without repair is thus increased, and should a movable commutator be fitted, the trouble of taking care of a machine would be reduced to a minimum. There are four varieties, or classes, with capacities of 70, 150, 250, and 500 lamps, and the number of magnets depends on the size of the machine. Each pair of cores are in series. If two or more pairs are used, the pairs are thrown in parallel circuit.

The resistance of the field coils may be roughly expressed by $\frac{3{,}000}{L}$ where L is the maximum number of lamps. In the 70 lighter this resistance is 40·4 ohms cold, and 41·5 warm, and the field is in parallel circuit with the external circuit. The machine generates an electromotive force of about 110 volts and runs very quietly. Ordinarily 60 lamps would be the proper load if running for a long time, but 85 can be readily carried for a shorter period. The ordinary limit to the power of a machine is the heating of the armature, which depends upon the total volume of current flowing. The armature has a resistance of ·16 ohms cold and ·20 warm. With a difference of potential of 100 volts at the terminals, the field coils would require 10,650 foot-pounds of electrical energy expended per minute, or ·32 horse-power, *i.e.*, about a pound of coal per hour. The energy lost in the armature would be $c^2 \times 8{\cdot}848$, c being total current in ampères. With a circuit of seventy 140-ohm lamps, the external resistance, including the field coils, but not the conductors which are very low, would be two ohms, over 9·5 times the internal. My experience with the larger machines of this type does not warrant me in commenting on their performance, but from the knowledge of their construction, I should judge their efficiency to be about the same. 9 or 10 horse-power should be delivered to the pulley of the 70-light machine.

2. The second class comprises machines with magnets as in the first, which may be coupled in series, or in parallel circuit making their resistance about ¼, and enabling a given electromotive force to be obtained with a lower speed. The armature is built up of iron discs, and has a sheathing of copper bars, connected across the ends by copper discs. It is of very low resistance, in the ordinary size 1-10th of that of the 70-lighter. It is run at the same speed, develops a lower locomotive force, and is suitable for lamps of lower resistance. The following table is from a careful test of this machine by Mr. J. A. Howell, at Stephen's Institute. These tests were made—the first, by means of the voltameter; the second, by calorimeter; and the third, by the electromotive force and resistance method. By "efficiency" is meant the ratio of the total electrical energy developed to the power required to turn the armature in the magnetic field. By "commercial efficiency" is meant the ratio of energy appearing in the external circuit to the power required to drive the machine, including friction.

DATA.	1st Experiment.	2nd Experiment.	3rd Experiment.
Time of duration	·15	·16	—
Speed of dynamometer	400·5	394·	355·
Resistance of armature	·016	·016	·016
Total resistance of circuit	·773	·696	·658
E.M.F.	64·74	55·10	53·00
C.	83·75	79·17	80·55
Efficiency	·955	·967	·935
Commercial efficiency	·861	·901	·87
Foot-pounds of electrical energy in—			
1. Armature	4965·	5604·	5026·
2. Field coils	4647·	4216·	3347·
3. External circuit...	230268·	233940·	198301·
Percentage of same appearing in—			
1. Armature	2·07	2·30	2·43
2. Field coils	1·94	1·73	[illegible]
3. Both	4·01	4·03	4·0[illegible]
4. External circuit...	95·99	95·97	95·95

These armatures are somewhat difficult of construction, bu[t it] seems to me their efficiency is so remarkable that the extra ex[pense] is warrantable, and I should like to see all the machines const[ructed] on this rather than on the wire principle.

3. This class comprises machines with armatures on the same plan as the last, but are much larger, of lower resistance and of double the electromotive force. The field magnets are horizontal, have twelve cores, and their resistance is about 1-7th that of the 70 lighter. The armature is connected directly to the engine, which is a well proportioned, high speed, non-condensing engine, known as the Porter-Allen; only three of these dynamos are in Europe, one being in Paris and two at the central station at Holborn Viaduct. The normal capacity of No. 3 is 1,000 lights, but it can be readily run up to 1,200 or 1,300, and by coupling the field magnets so that their resistance is about 4-9ths of the Holborn machine, Mr. Edison recently ran 1,630 lamps at twenty candle-power, and I have been informed that No. 3, before leaving New York, was tested with 1,320 lamps for fifteen consecutive hours, I suppose at sixteen candles. From Howell's experiments, one lamp of 140·5 ohms resistance required for an illumination of sixteen candles a potential of 99 volts, and used 3,107·41 foot-pounds of energy per minute. The potential and resistance give a current of 0·7046 ampères, which is about the average of five lamps. 1,320 lamps would then require 930·072 ampères, and the external resistance would be ·1064 ohms, or twenty-eight times the internal. Call the resistance of leading wires ·01 ohm, a tenth of the lamp resistance, which will give a lamp circuit resistance of ·1164 ohm. The resistance of the field magnets is 6·73 cold. Allow 5 per cent. increase in these coils, and 10 per cent in the armature for heating, and consider the conductor resistance as between the lamps and machines. Thence we have a difference of potential at the brushes, and terminals of the field coils, of 108·05 volts and a field current of 15·29 ampères, giving a total current in the armature of 945·36 ampères, and an electromotive force of 111·67 volts. This gives an equivalent of 73,090 foot-pounds in the field coils, 387,200 in the leading wires, 163,690 in the armature, and 4,064,050 in the lamps, making a total of 4,688,030 foot-pounds of electrical energy per minute. In the absence of exact data, suppose the efficiency of this machine to be 93 per cent., two less than that of the small machine before considered; then we would have 5,040,860 foot-pounds per minute applied to the axis of the armature, or 152·75 horse-power, of which there was expended in the lamp circuit 123·15, in the external conductors 11·73, in the field circuit 2·22, in the armature 4·96, and wasted 10·69—*i.e.*, 80·6, 7·6, 1·5, 3·3, and 7·0 per cent. respectively. Although 4·96 horse-power may seem a large loss in the armature, it is a very small percentage on the whole; yet a diminution of ·0001 ohms would diminish the loss by 3,916 lbs. per minute. We thus see how absolutely necessary it is to have the lowest possible resistance in the armature when dealing with large currents, the energy of which, expended within a circuit of given resistance, increases with the square of the current. Were this same current, 945·36 ampères, to flow through an armature of a tenth of an ohm resistance, there would be a loss of over 118 horse-power, and were the resistance one ohm, nearly 20,000 foot-tons would be converted into heat per minute. In fact, it would be practically an impossibility to build an armature of this resistance to stand the current. Another instructive calculation may be made by reducing a armature to a nominal equivalent foot conductor. In this it is not necessary that we may compare with another machine to consider the relative intensities of the field. All machines have certain parts of the conductors which are inactive, and the less this proportion the better for the machine and higher its efficiency. In this generator there are 98 bars on the armature, the average length being four feet nine inches. The circle of revolution is 27·5 inches in diameter. At each end are 49 circular plates, each of these being the equivalent of a conductor 27·5 inches long. The speed of the engine is about 320 revolutions. From these data I find the useful part of the armature equivalent to a conductor one foot long, moving with a velocity of 15,682 feet per second, and the inactive part equal to a foot conductor with a second velocity of 6,507 feet, or the whole equivalent to a foot conductor with velocity of 22,189 feet per second. With an electromotive force of 111·67 volts this gives a foot conductor a second velocity of 198·7 feet per volt developed, and with 5,040,860 foot-pounds per minute, an absorption of 3·78 foot-pounds in a foot conductor per foot per second, of which 93 per cent. is developed into electrical energy. This is an admirable showing, and affords some data on which to build a still larger machine. I am inclined to think that were the armature built of rings instead of discs, even less power would be wasted. The limit to the size of machines to be built is reached when we determine how much waste can be afforded, and how much must of necessity be lost in the armature. The current generated is taken off by four pairs of independent brushes, the surface of the commutators being slightly amalgamated. The sectional area of the brushes on one side is about 4 square inches. The commutator blocks should be movable, and I understand all large machines now are so constructed. I have seen the largest machine here run one lamp of about 16 candles, and at other times 800 to 1,000 at from 20 to 25 candles, or even higher.

The potential is such that the commutator brushes can be readily grasped. The armature heats moderately—the radiation being hindered by a thorough insulation—but a blower forces air around it to prevent undue rise of temperature. The engine seems to me an excellent one, and now that certain opposition to large dynamos has been hushed, the engine becomes the moot point. The general experience has been that high speed engines on variable work and long runs have given a great deal of trouble with lost action, back lash, loosening nuts, and wear of piston, cylinder, valves, and guide-bars. In a large system of distribution the variation of load is much more gradual than in a tool shop or factory, and consequently the work is better adapted for a high speed engine than many other kinds might be. For large engines there may be urged less wear and tear, fewer individual parts to look after, less liability to a break down, a greater number of good engines to choose from, and higher economy. In favour of the higher speed engine, there is less boiler space required, the individuality of each engine, the less inertia, and in case of break down the disabling of a much smaller part of the plant. I confess to have had a prejudice against high speed engines, but this has mostly disappeared, and an inspection of one of the engines at Holborn Viaduct shows it to be in thoroughly good condition. The boilers are the Babcock & Wilcox patent, adapted to quick steam and high pressure. They need to be well taken care of, but are widely and favourably enough known to engineers to need no comment.

LAMPS.

On account of the need of having the external resistance high compared with the internal, and this ratio necessarily increases with the volume and current required; the resistance entering into a part of the lamps and not into others; the necessity for allowing a smaller illumination for different lamps; and from the fact that a given illuminating power can be obtained from a fine filament with a less loss of energy in conductors than from a coarse one, Mr. Edison has aimed at carbons of a very high resistance. There have been difficulties in the way by no means easy to surmount. One is that carbon diminishes its resistance when hot, another that strength, elasticity, and life are wanted. A third is that lamps of like illuminating power should have the same resistance and certain to last a reasonable time. Remarkable advance has been made, and 16-candle lamps are now made of 240 ohms resistance cold, and 140 hot, and 8-candle lamps of about 475 ohms cold and 275 hot, exceedingly strong and elastic, and of long average life. This life is still quite variable and it cannot be foretold, about 1,100 hours being their average at present. Made of the finest bamboo, they are fibrous, of very even texture and very fine. The carbons are joined to copper terminals of the platinum wires in the glass, the copper clamps and ends of the carbons being plated in a solution. The platinum wires are sealed in a hot press joint at the inner end of a tube sealed in the neck of the globe, whence copper wires lead to brass connections, which are brought into contact with similar connections in the socket. The carbons are so elastic that they will vibrate from one side of the globe to the other. When hot they are less elastic. For lamps of higher illuminating power the width of the carbon is increased while the thickness remains about the same. The use of two or more carbons is not a practical arrangement. This gives about double the illuminating surface, half the resistance, and requires double the energy. There is room for great improvement in the matter of lamps of high power, for I have no doubt that in the near future incandescent lamps of 200 or 300 candle-power and higher will be perfectly practicable. It has been said that lamps should have the highest possible resistance. This is not so. The carbons have been reduced about as far as possible in width. They may be made thinner, and thus a step made to lighter weight, higher resistance, and greater economy. But the real limit is the potential which can be used. The resistance of a carbon of given illuminating power must depend on the foot-pounds of energy expended and the potential at the terminals. The following table will show the resistances for several degrees of potentials and economy:—

Foot-pounds of Electric Energy used in Lamp per minute.	Number of Lamps per H.-P.	Candles per H.-P.	Resistance of Lamps in ohms when the Electromotive Force is in volts. 100	125	150	175	200
3,000	11	176	147	246	332	452	590
2,500	13·2	211·2	177	293	398	542	708
2,000	16·5	264	221	367	498	677	885
1,500	22·	352	295	489	664	903	1180

Already there has been produced about twelve lamps per horse-power, but I think that 2,000 foot-pounds of energy is as low as can be hoped for, and I do not feel that we should go above 150 volts potential at the lamp terminals. If this end can be obtained, the carbons must have a resistance of 498 ohms hot, and there will be produced over 260 candles per horse-power of electrical energy. I am confining these computations and statements to the case of lamps not giving over 16 candles, a standard of which the long use of gas has led to the adoption. The difference in work between a 140-ohm lamp at 15 and 16 candles power is about 84 foot-pounds, which will allow two ohms difference of line resistance for two lamps, *i.e.*, about 1,000 feet of No. 15 wire, or one mile of No. 8. Neither a high resistance nor a high potential is necessary to get a certain candle-power with a certain expenditure of energy in a lamp of given mass, but a greater current is necessary with the lamp of low resistance. This means a greater loss in the conductors, a loss efficiency of generators, and a much more limited distribution. Let me illustrate by a particular instance. A current of 400 or 500 ampères flowing through a conductor an inch in diameter, exposed to the air, would heat it very appreciably, say, 15° C. above the atmosphere. Now, what are the conditions in a system of distribution? The cable must be thoroughly insulated, and hence there will not be a free radiation of heat, although surrounded by moist earth, and the rise in temperature will be fully as great as in the case of the exposed conductor. But copper increases its resistance ·4 per cent. for each degree of rise. Supposing our lamp to have but a fourth of the resistance; with the same economy double the current would be required. If the resistance of the cable were fixed, this double current would develop four times the heat, but the increased temperature is attended by a rise of fully 30 per cent. in resistance, and the work done would be more than five times as great. Further than this, the temperature of the cable would be dangerously high.

METERS.

After many trials of various kinds of meters, or registers, Mr. Edison has adopted that which depends on electrical deposition, and has selected pure zinc for his plates, a strong solution of sulphate of zinc for the liquid, and places the register in a shunt circuit, allowing but about 1-800th of the current to pass through it. The weight of

deposited in one hour by the ampère of current is 1198·8 milligrammes. Polarisation is remarkably weak, and there is very little variation when a large number of the meters are tested together. Very careful weighing is necessary, and probably the popular desire to see for one's self what current one is using, and thus have a check on the readings of the company, could only be met, with this meter, by having a competent supervisor of the weighing who was in no way connected with the company. But in the meter economy and accuracy seem to have been the objects. Error from a change of temperature is almost entirely eliminated by a proper proportion of plates and solution, the resistance of which changes in opposite directions.

SAFETY ARRANGEMENTS.

Much has been said about the danger of fire from the introduction of electricity; but if the wires are properly laid, and means be taken to cut out a circuit, when for any reason a short circuit takes place, causing of course an instant increase of current, there is no cause for apprehension. All wires, besides being insulated, should either be run through the brick or stone of a structure or run along the walls, and covered by a moulding to prevent accidental joining of the two wires. Mr. Edison has adopted this plan. The switches have large bearing surfaces, and the contacts are broken sharply to prevent arcing. Aside from these arrangements, he has introduced a feature which is an absolute necessity, and which is now recognised essential to all systems of distribution for domestic purposes. This is a weak point in every main, derived, and sub-derived circuits—a bit of wire of lead and tin alloy, which is mounted in a plug and can be readily replaced when destroyed. In the event of a short circuit the sudden increase of current fuses this wire before it can possibly heat the copper conductors. This is, I think, one of the most admirable features in this system.

Having thus considered the principal points of Mr. Edison's system in detail, let us look at it as a whole. At the late Crystal Palace Exhibition there were about 1,075 mixed lamps distributed, all supplied by the same main conductors, and arranged in branch circuits with switches and safety plugs. These were equivalent to 840 standard lamps, and the current was supplied by twelve dynamos. One object in designing the plant was to get an independence of power such that the failure of any part would not cause extinction of the lamps. The motive power consisted of three Robey, non-condensing, double cylinder engines. Each fly-wheel gave motion to a loose pulley, which through a movable cone pulley drove a section of shafting to which were belted the dynamos. Thus the breaking of an engine would stop four machines only; two could be stopped by shifting the cone pulley, and one by throwing off its belt. This arrangement steadied the current, and minimised the effect due to any irregularity of an engine. With 70 standard lamps as the full work of a dynamo, one machine should be added to every 70 lamps added to the circuit, so that the relation of internal and external resistances should remain the same. The internal resistance was about ·017. The 12 pairs of field coils, like the machines, were in parallel circuit, making their resistance 3·46 ohms, and the external resistance was about ·17 ohms. The engines run at 120 revolutions, driving the dynamos at 1,150. The machines run very quietly, with very little sparking. In the field circuit was placed the regulator, a series of open wire coils joined to segments of a circle around which travels an arm which by successive contact throws into circuit one or more coils, thus increasing the resistance of the field circuit. By the movement of a lever the lights could be thus regulated in intensity. The eye is a very poor judge of this intensity, and to indicate an abnormal potential a magnet is bridged across the mains just as the lamp is done, and the tension of the armature spring regulated, so that when the potential increased, the increase caused the armature to move and a bell to ring. Such an arrangement, however, shows only the fact that the potential is too high, and in a larger system a much more delicate arrangement is used, the deflection of a spot of light on a graduated arc of large radius. The manual labour now used could be readily dispensed with, for the current in the galvanometer circuit can control a delicately adjusted armature, which being moved one way or the other would throw into action mechanism to operate the lever, or can close or reverse the current of a small motor, which moves the lever one way or the other. The use of the regulator should be as limited as possible, because a resistance which has no other function than diminishing a current is not to be commended, therefore very few coils should be in circuit for any length of time, and the regulator should find its office principally in meeting any sudden changes in the external resistance. The small amount absorbed in regulation, about the energy used in four lamps for a 70-light machine, cannot be objected to. Whether the shunt system, or the method of separate exciting for the field magnets will be found preferable, will probably be ascertained only after considerable experience. With but few machines in action, I think unquestionably the shunt system, with comparatively high resistance of the field coils, is by far the best. These are matters of relative economy and practice, not at all of the successful distribution of electricity. Just as small machines may be coupled in parallel circuit, so may large ones, with satisfactory results. This coupling of machines of low resistance in parallel circuit is absolutely necessary, and the only way practicable for a system of distribution directly from the generators. When so joined, loss of energy in the armatures bears precisely the same ratio to the total energy expended as exists in a single machine. Were the lights at the Crystal Palace furnished by one machine, having an armature with a resistance equal to that of one of the armatures of the small machines, there will be a loss of over 90 horse-power, enough to drive nine machines. When the machines are joined, there is the same immunity from harm in case of contact as in a single machine.

At Holborn Viaduct there are from 1,100 to 1,150 lamps furnished from the central station. The system of distribution is that of multiple arc and branch circuits. It is this question of distribution over large areas to which Mr. Edison has given a great deal of thought, and has, I think, satisfactorily solved the problem. Imagine two great sheets of copper in juxtaposition, maintained at a certain difference of potential. If in either there exists a difference of potential at any two points there will be a general flow of electricity set up to restore the plate to a state of equilibrium. If these plates be joined by conductors, currents will flow proportional to the difference of potentials and the resistance of the conductor, just as if these plates were the terminals of a machine. Let such plates be the terminals of a machine, or, better still, of several machines, and let the connections be made at several points. There would be a system of distribution, as far as regards the conductors, on the most perfect principles; and if the resistance of the connecting paths is less, that is, the number of paths greater, at one point than at another, there would be at that point a greater tendency to reduce its potential, and currents would flow to it from the surrounding parts. Perforate these plates, or replace them by networks, or meshes of cables, and we have a perfectly practicable method of providing a distribution, and I think the most satisfactory one. The way of laying down a district on this system is to lay the main cables in each street, and wherever they cross join like to like. This is to be supplied from the central station at several different points, which points are determined by the relation of the size of the conductors and the resistance of, and allowed variation in the intensity of the lamps. The direction of the current in the street conductors will not always be the same, but will change so that the maximum flow is towards the point where there is the greatest demand. The relative sizes of conductors are calculated for the maximum currents they are to carry, and in order that the percentage of loss may be the same a double current would require a conductor of double cross section. The main conductors diminish in size as the distance from the several sources of supply increase, and the several districts in the city, each being primarily fed by a single system of generators, are joined together. If one-half of these conductors were broken the remainder could still supply the district. Small wires from every part of the city can be taken to one central office so that the actual state of the potential may be known at any instant at any point, and even an automatic record kept. Thus one man can keep constant supervision over the whole system, having thus a check on the engineers, and by telephonic communication give the necessary directions to increase or lower the supply. In every dynamo room a dial can be placed in a shunt from the cable of each machine which will indicate the number of lamps or the amount of current which the machine is supplying. I have made no mention whatever of the application to power, which I will consider later. Nor have I spoken of storage batteries in connection with this system, and I think with Mr. Edison that they are not a necessary adjunct. The variation of light would be remarkably small, and the failure, as far as the street mains are concerned, is practically impossible. There then remains the question: What is the liability of break down at a central station? If there is but one such station, the only way in which it could be disabled would be the blowing up of the major parts of its boilers, and this is not very probable. The break down of a single engine, the failure of one or two armatures, is quite possible, and we may say at times probable. But such a breakage would not seriously affect the supply, for, aside from the fact that there would probably be a reserve dynamo, the machines can be easily run to over their normal power. In a city the entire destruction of a central station would not put out the lights in its own district, for the mains would be supplied from those of the surrounding districts. The calculation of the size and number of the supply and distributing means is a work of most careful engineering. It involves the cost of iron and copper, of coal and property, of labour, of capital invested and interest required—in short, how much of the energy of the coal can be wasted, and in what part of the system. So each city must be the subject of special calculation, and, although a complicated work, it is perfectly practicable.

Such is a brief *résumé* of Mr. Edison's system, as it has appeared to me after long and thorough study, a system in the fullest sense of the word—one of supply, measurement, and consumption, elaborate in detail, broad in conception. When we consider the present uses of electricity, and the uses which will be developed when it is at every householder's command, we will be more able to appreciate the importance of Mr. Edison's work, and recognise his clearness of conception and great foresight in thus practically solving the great problem of the distribution of electricity.

(*For discussion on this paper see page* 179.)

A NEW ELECTRICAL CONTACT MAKER.

[Paper read before Section A, Tuesday, August 29th, 1882, By Prof. H. S. HELE SHAW.]

THE author first calls attention to the want of an absolutely reliable and at the same time sufficiently sensitive electrical contact maker. Such an instrument is often required to measure or control the relative motion of bodies in conjunction with delicate clockwork. He then proceeds to discuss the ways in which such contact may be made. In theory there is no distinction in the modes of doing this, but practically they may be separated into—

(1.) Relative motion of the two terminal surfaces normal to both.
(2.) Motion tangential to both.
(3.) Motion compounded of these two.

These modes are separately discussed, and also the various objections with all when solid terminals are used. The use of a liquid terminal with which the other terminal being solid is brought into contact obviates most of these objections. Of all liquids mercury is the only one which can practically be employed. There are, however, two

objections to its use which have prevented its being hitherto adopted for more than temporary and experimental purposes. These are:—

(1.) The fact that it readily combines with oxygen on the passage of the electric spark.

(2.) The difficulty of making a contact maker of this kind portable.

The earliest form of instrument in which the author has endeavoured to overcome these difficulties, was then shown on a diagram and described. Its principle of action is briefly this: A short glass tube, closed at the upper end (such as an inverted test tube), is filled with mercury and inverted in a vessel of mercury. The mercury in the tube is then partially displaced by hydrogen gas. A very light bent lever, consisting of a platinum wire, passes through the mercury into the gaseous space, and there makes contact between the mercury below and a smaller quantity of mercury in an insulated capsule above the other portion, but within the tube. This lever works on a pivot, being actuated from the outside by the escapement of an ordinary clock, and is extremely sensitive in its action. The positive and negative poles of the terminals are respectively connected with the mercury in the capsule, and that in the vessel below. It is evident that although the lever is always in electrical contact with the latter, the circuit is only completed when it is brought into contact with the former. Accounts of experiments showing the satisfactory action with this apparatus are then given. Finally, the most recent form of apparatus which is portable is illustrated and described.

RECENT PROGRESS IN TELEPHONY.

[Paper read before Section G, Monday, August 28th, 1882,
By WILLIAM HENRY PREECE, F.R.S.]

THE telephone was first introduced to the British public at the meetings of the British Association. In 1876, at Glasgow, Sir William Thomson startled all his hearers by announcing the fact that he had heard, in Philadelphia, Shakespeare quoted through an electric wire, by the aid of the invention of Mr. Graham Bell, which he then pronounced to be "the greatest by far of all the marvels of the electric telegraph." In 1877, at Plymouth, I had the pleasure of showing in actual operation the finally developed instrument now known as the Bell Telephone, which I had just brought over from America, and conversation was actually maintained between Plymouth and Exeter. Five years have elapsed since then, and it is fitting that the British Association should hear of the progress made in the application of this astonishing apparatus.

In 1877, it was simply a scientific toy; it has now become a practical instrument. £1,550,000 capital is already embarked in its extension in England, and it is earning a revenue of £109,000. Hitherto it has been practically a monopoly in the hands of a private company, who hold the controlling patents, and of the Post-office, who possess the controlling power, but owing to the policy of the present Postmaster-General, this monopoly has been broken up, fresh patents have come into existence, and we are about to witness severe competition. It is often said that competition in any business will have the effect of reducing the rates charged to the public, but the experience of the past in railways and telegraphs scarcely teaches this lesson; competition does not always benefit the public. Undue competition tends to lower the rates for a time, but it eventually leads to amalgamation, to the absorption of the weak by the strong, to swollen and watered capital, and finally, in many instances, to higher rates to a too-confiding public. Competition however induces better service, and ultimately, in this respect, the public gain.

The free traffic in patents, however, leads to jobbery and speculation of the worst type. We have recently seen a mania for electric speculations that almost rivals the South Sea Bubble period. The public have wildly rushed into ill-matured schemes that have swollen the purses of gambling promoters, have turned the heads of inventors, have retarded the true progress of the beneficial application of this new science to the wants of man, and have thrown away millions upon imperfect schemes. Much has been said against the monopoly of the Post-office in telegraphic business, but it has, at any rate, the merit that it has checked the rapacity of company promoters and patent-mongers in that branch of the practical application of electricity, while no one can assert that it has checked the progress of telegraphy. During the first week that the telegraphs in this country were transferred to the State, the total number of messages transmitted was 26,000, while in the week ending August 11th, it amounted to 724,000. There is no inventor who can assert that his scheme has not received proper consideration, nor show a real improvement that has not been adopted and remunerated; while the improvements of the Post-office itself are freely adopted by other countries, and America itself, the home of the inventor, has found the advanced system of England worthy of acceptance.

Receivers.—The original telephone receiver of Bell has scarcely been improved upon; it remains in form and construction very nearly the same as that which I exhibited in 1877. The perfection of its working depends upon the truth and perfection of its manufacture. It is now more solid and substantial than it was at first, more powerful magnets are used; but still it is the same simple, marvellous, and beautiful instrument that I brought over from America. Mr. Gower has increased its loudness by varying the form of its various parts, and using very powerful horse-shoe magnets of peculiar form; but experience shows that loudness is always obtained at the expense of clearness of articulation; and, although for many purposes the Gower-Bell instrument, which is adopted by the post-offices, and is now in use to connect together all the sections of the British Association scattered through the town of Southampton, is more practical, nothing for delicate articulation surpasses the original Bell.

The Paris Exhibition of last year, so fruitful in electrical novelties, did not bring forth any marked improvement in telephonic apparatus. It was noticeable chiefly for its practical applications of the telephone, and particularly to the transmission of singing and music to a distance. M. Ader's modification of Bell's receiver is that almost universally used in Paris. It is a very handy, pretty, and convenient form. He utilises a principle which he calls "surexcitation." A thick ring of soft iron is inserted between the ear-piece and the diaphragm, and this is said to increase the attractive power of the little horse-shoe magnet upon the vibrating iron diaphragm. A simple experimental apparatus of M. Ader's shows that there is some foundation for this fact: when a thin steel spring is adjusted close to the poles of a magnet without being attracted by them, the near approach of a mass of iron to the spring will cause it to be attracted by the magnet.

D'Arsonval has also modified the Bell receiver. He has placed the coil in a powerful magnetic field of annular form, and has thereby concentrated the lines of force upon the induced coil. He brings the whole coil within the influence of the field. The effects are considerably magnified, and the increased loudness is not accompanied by the usual loss of articulation. Speech is said to be reproduced without any change of *timbre*.

Telephone receivers of the Bell type are all based upon the magnetic effects of currents of electricity flowing around magnets or bars of soft iron.

The rapid and rhythmic magnetisation and demagnetisation of a bar of iron, or the increment and decrement of the magnetism of a magnet, will produce molecular disturbances, in its own mass and in the matter about it, that lead to the oscillatory motions of the whole, which produce sonorous vibrations that can be made manifest by various devices, and particularly by that patented by Graham Bell.

Other principles of electricity have also been utilised for telephonic receivers.

For instance, Mr. Edison used the electro-chemical effect. The decomposition of a chemical solution in paper or on chalk by the passage of currents through it produces a modification of the friction of two moving surfaces, which can reproduce sonorous vibrations, and the result is a very loud-sounding apparatus. I myself had the pleasure, in 1880, of submitting to the Royal Society a receiver based on the electro-thermal effects of the current. The passage of a current through wires always heats them and therefore produces expansion. If the wire be made fine enough, the heat is generated and dissipated so rapidly, the expansion and contraction are so quick, that sonorous vibrations are the result. Although I was able to speak through it very clearly, I have not as yet developed this instrument into a practical form. Professor Dolbear has recently utilised the electro-static effects of currents. His receiver is even more simple than that of Bell. Two flat circular discs of metal are rigidly fixed very close to each other in an insulated case of ebonite. When one disc is electrified positively by a charge of electricity, the other is electrified negatively by induction. These two opposite states produce attractions varying in force with the strength of the signals sent, and the result is that, when telephonic currents are transmitted, we obtain sonorous vibrations, and consequently, the reproduction of speech.

Many other forms of telephone receivers have been devised and exhibited, in fact I have recently seen quite a crop of them; but as they involve no new principle, and introduce no particular improvement, having been brought out chiefly to try to avoid existing patents, I pass them over, and proceed to the next branch of my subject.

Our present Patent Law is, unfortunately, in so disorganised and chaotic a condition that evasion is often possible, and hence the questionable morality of doing a thing in another way in order to avoid the incidence of a royalty, is practically encouraged.

The possession of a patent is now no guarantee of property: it is granted without any discrimination, and cannot be upheld without tedious litigation and wasteful expenditure before a non-technical and scientifically incompetent tribunal. We therefore cannot hope for any virtue in English inventors or security for real improvements until our law is thoroughly revised. The question is before the House of Commons, and when wordy agitators have fully exhausted the patience of our legislators, we may hope for some attention to so real and pressing a want.

Transmitters.—The great novelty and peculiarity of Bell's telephone was that the receiver and transmitter were similar and reversible. Sonorous vibrations of air impinging on an iron disc caused it to vibrate in front of a magnet, around one pole of which a portion of an electric circuit was wound. These vibrations of a magnetic substance in a magnetic field produced currents of electricity in the coil of wire on the magnet, varying in strength and direction with the sonorous vibrations, which, proceeding along a wire to a distant station, there varied the magnetic strength of a similar magnet so as to vary its attractive force on a similar disc, by which it reproduced the motions of the first disc, and thus, reproducing the sonorous vibrations of the air, repeated speech. The currents, however, were very feeble; much energy was lost *en route*, and the effect scarcely attained a practical standard. Mr. Edison showed how to strengthen these currents. Taking advantage of a peculiar property of carbon, which was supposed to vary in electrical resistance with the amount of pressure brought to bear upon it, he caused the vibrating disc which was spoken against to press upon a button of carbon, and so to vary the strength of a current of electricity passing through it. This varying current, passing through the primary wire of an induction coil, set up in the secondary coil more powerful currents than the Bell instrument produced, and caused louder and more marked effects at the receiving station. Professor Hughes went a step further. He found a combination of materials that were directly affected by sonorous vibrations, which he called a "microphone," and he proved that the effect of the carbon transmitter of Edison was not due to any influence of varying pressure on the mass of the carbon, but was a phenomenon of loose contact. He found a new fact in nature, and

he startled the scientific world by introducing an instrument which did for minute sounds what the microscope had already done for minute objects. By the light thrown on the theory of the instrument by Hughes, Edison's carbon transmitter has been so improved by Blake, Hunnings, Moseley, Anders, and others, that little apparently remains to be done. The telephone as a speaking instrument is now well-nigh perfect. It is quite possible to swear to a friend's voice at 100 miles distance. The difficulty of making the telephone a practical instrument under all circumstances is not due to any defects in the instrument itself, but to disturbing influences external to it, and consequent on its surroundings. The very perfection and sensitiveness of the apparatus itself are its chief enemies.

The true action of the microphone, or carbon-transmitter, is very little understood: it introduces into a closed electric circuit, through which a current is flowing, a resistance which, varying exactly with the sonorous vibrations impinging upon it, causes the current to undulate in a way exactly analogous to the varying sound waves. This effect is generally assumed to be due to a greater or less intimacy of electrical contact between two semi-conducting surfaces abutting upon each other; but there is now little doubt that it is due to effects of heat generated by the passage of electricity between two points in imperfect contact, whose relative distance is variable. Carbon is the best material for the purpose—first, because it is inoxidisable and infusable; secondly, because it is a poor conductor; and thirdly, because it has the remarkable property of having its resistance lowered when it is heated—the reverse of metals. This observation is due to Mr. Shelford Bidwell.

The resistance of microphones is very variable: some only give 10, while others give 25, and some even 125 ohms. The best transmitters that I have worked with (Moseley's) give an average of 20.

Attempts have been made to apply mathematical analysis to the determination of the best form and arrangement of microphones, but at present the microphone defies mathematics.

Theory would lead to the conclusion that a carbon transmitter should have the lowest possible resistance, but practice does not confirm that idea.

Theory again asserts that the resistance of the secondary coil of the induction coil should be equal to that of the line it works, but practice proves the very reverse. On a line giving nearly 1,800 ohms resistance, the best effects were produced with a secondary wire of only 30 ohms resistance. The fact is that the conditions due to heat in the microphone, and to self-induction in the induction coil, are very complicated, and are not yet sufficiently understood to bring the phenomena they affect within the region of mathematical analysis.

Accessories.—I do not intend to speak here of the bells, calls, switches, &c., used in carrying out telephonic operations: there has been nothing that is particularly novel introduced, or that was not previously used in telegraphy. In fact, the whole operations carried on in connection with the so-called "exchange" working are simply telegraphic, and are still in a somewhat tentative condition.

Long-distance Speaking.—I have said that the difficulty in speaking is chiefly due to the environment of the wires employed. Were we to erect a wire from Land's End to John o' Groats, upon lofty separate poles and away from all other wires, there would be no difficulty whatever in speaking between those two places. Conversation has been held in America over 410 miles; in Persia it has been effected between Tabreez and Tiflis, 390 miles apart; in India, over a distance of nearly 500 miles; in Australia, of 300 miles; but in all these cases it was done either at night or under exceptional circumstances, and in all cases the wires were overground. Had they been underground or submarine, the case would have been very different. Conversations have been held between Dover and Calais, between Dartmouth and Guernsey, and between Holyhead and Dublin, but I know of no case where any persons have spoken through more than 100 miles of submerged cable. The reason of this diminution of speaking distance is due to the electro-static capacity of the telegragh line, which absorbs the minute quantity of electricity that makes up the currents employed for telephonic purposes.

In every submarine cable, before a signal can be made at the receiving end, the whole cable must be charged up with electricity, and if there be not sufficient electricity sent in to effect this purpose, practically no signal appears at the distant end. With telephone currents on long cables the whole of the electricity is, as it were, swallowed up—that is, none appears at the distant end, or, if it does appear, it is rolled up in one continuous wave, bereft of those rapid variations that reproduce sonorous vibrations. The newspapers said that the sound of the bombardment of Alexandria was heard at Malta; but, in the first place, the experiment was not tried, and, even if it had been tried, it could not have succeeded. The use of underground wires very seriously impedes telephonic extensions, and with our present apparatus and present knowledge we cannot readily speak over greater distances than 20 miles.

Disturbances.—But there are other disturbing influences at work of more serious import.

When two or more telephone wires run side by side, what is said on one can be overheard on all the others; and when a telephone wire extends alongside telegraph wires, every current on the telegraph circuit is repeated in the telephone, leading to a hissing, frying, bubbling sound that is not only very irritating, but which on busy lines entirely drowns speech. When music is transmitted on one wire, it can be heard equally well on all wires running parallel and contiguous. This is due to induction and to leakage.

(A.) *Induction.*—Induction is a term employed to designate the peculiar influence which electrified and magnetised bodies exert upon conducting and magnetic masses in their neighbourhood. If two wires run side by side for some distance, every current of electricity sent upon one wire will produce two currents in the contiguous wire, the one at the commencement and the other at the end of the primary current of electricity. The greater the intensity, and the more sudden and abrupt the commencement and the ending of the inducing the greater effect it has on the induced wire. Those instruments, consequently, which reverse their currents the most rapidly and suddenly, produce the greatest disturbance. The powerful alternative and intermittent currents used for certain electric light systems are death to telephones: they cause an incessant roar that renders speech an impossibility. There are some apparatus in telegraphy that require very powerful currents to work them, which are equally detrimental. Many attemps have been made to cure this evil.

1. The sensitiveness of the receiver has been reduced to lessen the influence of the disturbing currents, and the strength of the telephonic transmitting currents has been increased so as to overpower the induced currents.

2. The influence of one wire on the other has been screened off by inserting metal coverings in connection with the earth between them.

3. The suddenness of the rise and fall of the inducing currents has been modified by the insertion of condensers or electro-magnets.

4. Counterbalancing or neutralising effects have been set up by counter-induction apparatus.

But all these plans, and many others, have been proved either only partially successful or wholly abortive; the only effective mode of curing the evil at present practically used is to employ a complete metallic circuit, so contrived that the two wires are in very close proximity to each other, or that they twist round each other, so as to maintain a mean average equality of distance between themselves and the disturbing wires. When we have the two wires of a circuit kept at the same mean distance from the disturbing causes, however near they may be, the influence on each must be identically the same, and as the one is used for going and the other for returning, the similar influences must be opposite in direction, and they must therefore neutralise each other. This plan, which was originally devised for underground wires by Mr. Brookes, of Philadelphia, was found to be absolutely true in practice, and the Post-office, having laid down many hundreds of miles on this system with perfect success, invariably constructs its circuits both underground or overground in this way. It is, of course, more expensive than a single wire, but the great gain—the absolute freedom from overhearing the privacy, and the absence of crackling—is well worth the extra cost. Wires in submarine cables are invariably laid up with a twist, so that no special contrivance is needed on such wires, and in underground wires not laid up together as cables, they are, as a rule, so close to each other that twisting is unnecessary; but for overground purposes twisting is essential, and special arrangements have to be carried out. Professor Hughes showed how this was to be done, and Messrs. Moseley carried it out practically in the neighbourhood of Manchester. The plan adopted by the Post-office for *two* and for *four* wires is shown by the diagram. It is simply and easily carried out, and entails no practical difficulty whatever.

In the neighbourhood of Manchester there are over 400 miles of overground double wire twisted on this plan, working efficiently and thoroughly. I have spoken to a friend 76 miles off, through wires that were erected on poles carrying busily-occupied telegraphic currents, without disturbance or difficulty.

(B.) *Leakage.*—The double-wire system is only absolutely effective so long as the insulation is good. The moment insulation fails, connection with the earth is made, and then we have disturbing causes, due to currents flowing through the ground, which are increased in proportion to the deterioration of the insulation. Hence, good insulation is essential to telephone working.

The discovery of the telephone has made us acquainted with another phenomenon. It has enabled us to establish beyond doubt the fact that currents of electricity actually traverse the earth's crust. The theory that the earth acts as a great reservoir for electricity may be placed in the physicist's waste-paper basket, with phlogiston, the materiality of light, and other hypotheses. Telephones have been fixed upon a wire passing from the ground floor to the top floor of a large building, the gas pipes being used as a return, and the Morse signals sent from a telegraph office 250 yards away have been distinctly read; in fact, if the gas and water systems be used, it is impossible to exclude telegraphic signals from the telephone circuit. There are several cases on record of telephone circuits miles away from any telegraph wires, but in a line with the earth terminals, picking up telegraphic signals. When an electric light system uses the earth, it is stoppage to all telephonic communication in its neighbourhood. The whole telephonic communication of Manchester was one day broken down from this cause, and in the City of London the effect was at one time so strong as not only to destroy telephonic communication, but to ring the bells. A telephone circuit using the earth for return acts as a shunt to the earth, picking up the currents that are passing, in proportion to the relative resistances of the earth and the wire. The earth offers resistance, and consequently obeys the law of Ohm: hence it is not only essential for a telephonic system that the earth should not be used on any electric light system, but it is also desirable that the earth should be eschewed for telephonic purposes. Thus, the double-wire system adopted by the Post-office and by the Société Générale des Téléphones of Paris, not only cures the ill-effects of induction, but it materially diminishes the disturbing influences of earth conduction. The four-wire system of the Post-office effectually checks leakage from one wire to the other, cross contact, as we call it in England, for each wire of the same current is always on a different supporting arm.

A telephone circuit when in connection with the earth gives distinct evidence of every visible flash of lightning, however far off the thunderstorm may be. No difference in time has been observed between seeing the flash and hearing the crash.

It is said that if a telephone be connected between the gas and water systems of a house, distinct evidence of every flash can be heard. There have been several cases of persons being knocked down while experimenting during a thunderstorm, but no personal injury has been sustained, although the apparatus itself [illegible] quently damaged. In England, at present, we have not found damage done sufficient to justify the employment of li[illegible]

protectors. The use of double wires diminishes the danger to a minimum. On the Continent and in America, however, telephones are invariably protected by lightning arresters where one wire only is used.

There are certain natural currents flowing through the crust of the earth. They are called "earth" currents, and at times acquire such considerable energy that with a telephone pressed to each ear, I have been told, although I have not experienced it, that the noise made is as though "your brains were boiling." This is due to the intermittent currents produced by the polarisation of the earth plates.

M. Van Rysselberghe has recently spoken between Paris and Brussels upon a wire nearly 200 miles long, which was used at the same time for ordinary telegraphy, but the experiment was made early in the morning (4 a.m.), and was effected by retarding the telegraphic currents, so as to modify the suddenness of their rise and fall, by means of condensers and electro-magnets. I am unable to understand the advantage of any gain in speaking on a wire which is detrimental to telegraphic communication. Speed is of more importance than speech, and we can telegraph much faster than we can speak. In England speed is everything, and we eliminate every influence that retards speed—condensers and electro-magnets in telegraph circuits are out of the question. M. Van Rysselberghe has endeavoured to extend the idea to cure the effects of induction by destroying the main cause of the disturbance—that is, by reducing the sudden rise and fall of the prime telegraphic currents; but to do this means to retard telegraphy, and we cannot afford in England to cripple the one system in order to benefit the other.

I have recently tried an extremely interesting experiment between this place (Southampton) and the Isle of Wight, namely, *to communicate across seas and channels without the aid of wires at all.* Large metal plates were immersed in the sea at opposite ends of the Solent, namely, at Portsmouth and Ryde, six miles apart, and at Hurst Castle and Sconce Point, one mile apart. The Portsmouth and Hurst Castle plates were connected by a wire passing through Southampton, and the Ryde and Sconce Point plates by a wire passing through Newport; the circuit was completed by the sea, and signals were passed easily so as to read by the Morse system, but speech was not practical.

The telephone is very rapidly gaining ground, and as improvements are effected in its accessories, in its installation, and in its mode of working, its use will still further extend. In Germany it is used very extensively for telegraphic business, there being 1,280 stations worked entirely by telephones, but in England it is not possible in the numerous open and public shops employed as post-offices to secure that privacy which the telephones require, nor have we yet got over our early prejudices, resulting from the errors made through the inability of the instrument in its earlier form to repeat the sibilant sounds. The instruments of the present day (thanks to the improved transmitters), however, transmit "s's" perfectly. By Mr. Smith's inductophone it is quite possible to make use of air between us to hear perfectly; so that air conducts sound, so does water, so does wire, and indeed with our present knowledge our difficulty is not so much to make things speak as to prevent them from speaking.

THE DEMANDS OF A SYSTEM OF ELECTRICAL DISTRIBUTION.

[Paper read before Section A, Friday, August 25th, 1882, By F. J. SPRAGUE, U.S. Navy.]

IN order to more fully understand the subject of incandescent electric lighting, let us consider the requirements graphically. I hardly need to argue that the multiple arc system is preferable to that of the series, and is in fact the only admissible one which can have any wide application. In fig. 1, let M be the generator, p and p' the terminals, R, R', R'', R''' circuits in multiple arc or parallel circuits; in other words, derived circuits from the same terminals. Now it matters not what the resistance of the machine, or the number, or resistance of the derived circuits, if they be connected to the same terminals, the current in any circuit will be equal to the difference of potentials at the points, p, p', divided by the resistance of the circuit in question. Nor does the addition or subtraction of any number of circuits make the slightest difference in the currents flowing in the circuits already established if this difference of potentials, $p - p'$, is kept constant. Consequently, the currents over the different paths will be inversely proportional to their resistances, and perfectly independent of each other. Since the external resistance diminishes with the increase in the number of the derivation circuits, the whole current flowing from the terminals will vary inversely with the external resistance. But the whole current is the current flowing through the armature. Since the internal resistance enters as a factor, although the difference of potentials at the terminals remains constant, the electromotive force of the machine does not. Let us consider a machine which, with an external resistance equal to the internal a, a given velocity and strength of field current, generates an electromotive force, ϵ. Call the external resistance $a\,r$, i.e., some ratio r of the internal, and let the current in the field magnets, independent of the current generated, or the velocity, or both, be changed as the external resistance changes, so that the difference of potential at the terminals may remain constant. Consider the change in the electromotive force of the generator. We have for two external resistances, one, a, equal to the internal, another, $a\,r$, greater or less, two currents.

$$c = \frac{\epsilon}{2a} \quad \text{and} \quad c^1 = \frac{\epsilon^1}{a(1+r)}$$

whence

$$\frac{c}{c^1} = \frac{\epsilon\, a\,(1+r)}{2\,a\,\epsilon^1} = \frac{\epsilon\,(1+r)}{2\,\epsilon^1}$$

But by condition of working

$$\frac{c}{c^1} = \frac{a\,r}{a} = r$$

$$\therefore \quad r = \frac{\epsilon\,(1+2)}{2\,\epsilon^1}$$

$$i.e., \ \epsilon^1 = \frac{\epsilon\,(1+2)}{2\,r} = \frac{\epsilon}{2}\left(\frac{1}{r}+1\right)$$

Differentiating this last equation with ϵ as the unit of electromotive force and ϵ^1 and r variables, we have—

$$\frac{d\,\epsilon^1}{d\,r} = -\frac{\epsilon}{2\,r^2}$$

and

$$\frac{d^2\,\epsilon^1}{d\,r^2} = \frac{\epsilon}{r^3}$$

which give the character of the curve of electromotive force under the conditions assumed. Fig. 2 gives the curve, with r and ϵ^1 as the

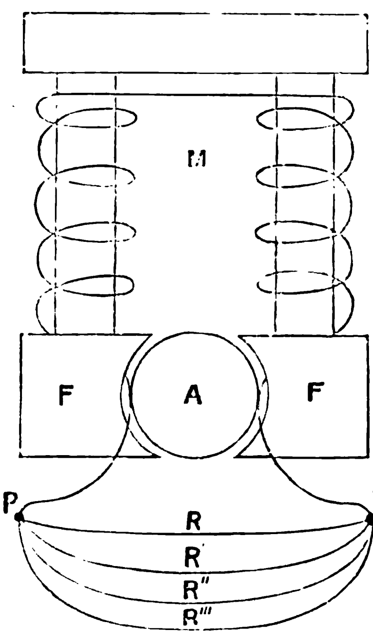

FIG. 1.

co-ordinates, x and y, with the bend near the origin, and with branches having for asymptotes the axis of y, and a line parallel to the axis of x, and distant $\frac{\epsilon}{2}$ from it. Vertical lines on to the axis of x represent the electromotive force compared with the unit, ϵ, which may

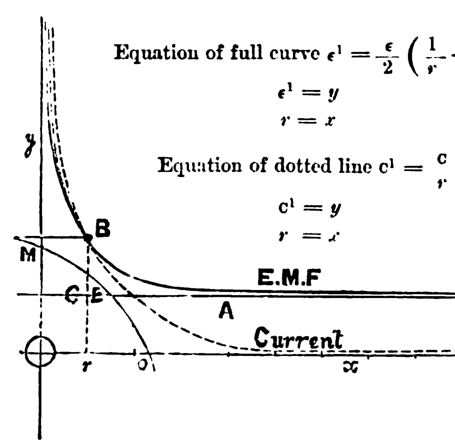

FIG. 2.

be of any number of volts, and the distance from the origin the ratio of the external to the internal resistance. This curve shows some important truths, a part of them familiar, others perhaps not so, concerning the economy and practice of the distribution of electricity, or the supplying of currents which will be inversely proportional to the resistance of the derived circuits, remembering meanwhile that the electromotive force of a machine excited by a separate circuit is very nearly proportional to the strength of the free magnetic field and the velocity of the armature. Of course this is somewhat affected by the heating of the metallic conductor for an increased current, the consequent change of resistance, the displacement of the magnetic field, and the heating of the iron part of the armature, if iron enter as a component. We notice

1. In a single generator the electromotive force is not proportional to the number of lights or motors, or the current developed.

2. No matter how high the external resistance, or how limited the number of derived circuits, the electromotive force of a machine required to maintain a fixed difference of potential at the terminals can never be less than half that developed when the external and internal resistances are equal.

3. The increase of electromotive force required as the external resistance decreases, or the number of derived circuits is increased, is very gradual up to the point where the external resistance is three or four times the internal, beginning then to rise more rapidly.

4. When the external resistance falls below the internal, the rise is very rapid, and if their difference is marked, then it becomes impossible to maintain a fixed difference of potential, because of the great increase necessary in the strength of the magnetic field and the velocity of the armature. A great amount of heat, and consequently of wasted energy, would be developed in the armature.

Let us consider another curve. Our requirements demand that the whole current should be inversely proportional to r, the ratio of external to internal resistance, or C being the current developed when the electromotive force is ϵ, $C^1 = \frac{C}{r}$. Let this curve be traced on the same axes as the preceding, and let the same unit of measure be used for C as for ϵ. (See dotted curve in fig. 2.) We find the curve somewhat similar to the curve of electromotive force; but it approaches both axes as asymptotes and falls rapidly below the first curve on the right, while rising above it on the left. A glance shows the relations of current and electromotive force for different ratios of external to internal resistance.

Note one curve more on the same sheet, though not with the same units; the curve of magnetic strength (M) is measured here vertically, the increase of field current being measured horizontally and to the left. The strength of the magnet increases at first quite regularly; the curve, however, flattens more and more as the current increases, until at the point of practical economic saturation a large further increase of the field current would produce but a much smaller ratio of increase of magnetic strength. Part of the energy of the increased current would undoubtedly manifest itself in heat both in the coils and in the iron of the magnet.

Now in a general distribution of electricity, a large number of derived circuits existing, there must necessarily be a low external resistance. Large currents flow through the generator, and we wish to have the energy of the current in the external circuit and not in the machine. It has often been said that the external resistance being thus reduced, the resistance of the individual lamps should be as high as possible. This is not so, for certain relatives exist between the weight and resistance of carbons, the illuminating surface, the electromotive force and current required, and the energy expended, which determine a limit. The expression for the work done is $\frac{\epsilon^2}{R} \times 44{\cdot}24$, or C^2 R, $44{\cdot}24$. Hence, with a given electromotive force the work done varies inversely as the resistance, and with a given resistance the work varies as the square of the electromotive force or the square of the current. If we increase the resistance to any ratio, d, of a given resistance, to maintain the same expenditure of force, we increase the electromotive force, but only in the ratio $\sqrt{d}$; so that with four times the resistance only twice the electromotive force would be required. Consider for a moment the size and shape of the carbon. If a carbon of circular form be used, the same weight would enter in a piece of half the diameter and four times the length of a given piece, giving sixteen times the resistance and twice the illuminating surface. With half the weight, we have the same surface and eight times the resistance. If the same energy be expended there will be necessary $\sqrt{8}$ times the electromotive force used with the coarse carbon, but $\frac{1}{\sqrt{8}}$ of the current. This would mean that with the same lamp expenditure for given illumination, one ton of coal would be used on the conductor for the high resistance lamp to eight tons for the low resistance one, a strong argument in favour of high resistance carbons.

Our first conclusion would then be to diminish the diameter and increase the length and resistance of the carbon, meeting this increase by an increased electromotive force. But in a system of general distribution, safety from fire, due to piercing the insulation, abnormal increase of current when short-circuited, and immunity from harm when by any accident the body forms a part of the circuit, demand a low electromotive force. Sir W. Thomson has said that this should never exceed 200 volts. Even this will give some persons a disagreeable shock, and a lower electromotive force may be used with advantage. Another point of consideration is the increasing of the resistance of a carbon while the length, diameter, and weight remain constant. As before, we see that the electromotive force must increase as the square root of the ratio of increase of the resistance, and this resistance must be determined by the limit of electromotive force, the size of carbon that can be manufactured, and the degree of illumination required. We will call this carbon, the carbon of smallest section, highest resistance, and standard illuminating power, the standard lamp. Now, while we have this standard, it is evident that we want to be able to increase the power of illumination at sundry points, and this must be produced, not by a corresponding increase of intensity per unit, but by an increase of the illuminating surface, and the increase of energy expended should be in no greater ratio than the increase of light. These remarks are partially founded on the fact that an increased temperature shortens the life of a lamp, and that the most reliable results are to be obtained by having carbons for all degrees of power of the same texture, and made by the same process as the standard, which standard should in every way be as near perfect as possible; all such carbons to have the same weight, length, degree of carbonisation, resistance, requiring the same electromotive force and expenditure of energy. For the lamps of higher power, we manifestly cannot use a carbon of greater length and correspondingly higher resistance, for this means a higher electromotive force, which is out of the question. Nor can we economically increase the diameter of a circular section carbon, for the resistance diminishes inversely as the square of the increase of the illuminating surface of same intensity. There are three ways where each lamp should be independent. One is by increasing the number of carbons in a lamp, they being arranged in parallel circuit; another by increasing the width of the carbon while the thickness remains the same—in other words, use a flat carbon, so that the illuminating surface will increase in the same rate as the weight of material. Now, with a double illuminating power we use the same texture of carbon, the same temperature and intensity per unit of surface, double the illuminating surface, one half the resistance, the same electromotive force, double the current and double the energy. A third method is that the carbon can be increased in length, while its resistance per unit of length and section is diminished.

Aside from the energy expended in the lamps and motors of a circuit a certain amount goes into the generator to magnetise the field magnet, and this is represented by the same expression we have already used where the difference of potential at the terminals of the machine and the resistance of the field coils enter as factors. There is another expenditure in the armature coils and the conductors dependent on their resistance and the current flowing, and still another at the commutator, which would be greatest with large currents. The friction of bearings, the slipping of belting, if used, the force necessary to overcome the inertia of moving parts consume a further portion of power. Of these components, which are over and above that power which is expended in the lamps and motors, those which magnetise the field, and overcome the friction of bearings and the inertia of moving parts, remain about the same whether one lamp or a thousand are in operation. This is considering the kind of machine I think necessary in a system of general distribution in which this extra work should be chargeable to a large number of lamps.

Consideration of the above and some other points, which will be obvious on mention, lead me to the following conclusions.

1. The resistance of the armature of the generator should be as low as possible compatible with the power necessary to furnish the required electromotive force.

2. The generator should be able to produce this electromotive force with the field magnets at less than the maximum economic saturation, and at a velocity less than that at which the armature can be safely run, in order that there may be a margin for increased efficiency in case of an unexpected demand.

3. The lamps and motors should have a high resistance, the standard lamp not higher than 475 to 500 ohms.

4. The resistance of the conductors should be as low as practicable, and should be graded in size for the current required.

5. The electromotive force of the generator should never rise to over 170 volts.

6. The lamps should be simple of construction, durable and cheap, and all alike.

7. The generator and the engine should be of the most substantial construction.

8. The points of derivation should all have, and all be maintained at, the same difference of potential as nearly as possible.

9. The energy necessarily lost in the armature and conductors of any fixed resistance for lamps of the same absolute economy varies inversely as the resistance of the lamps, or as the square of the current used.

10. Since in a single generator the total power used is not proportional to the number of lamps in circuit, a machine should be run nearly to its maximum capacity.

11. There should not be a single generator or a single circuit which may be destroyed, but such an arrangement that the external demands, both with regard to resistance and current required, may be met by suitable changes in the resistance and supply of the generative system.

12. The relation of internal and external resistance should be the same in a system as exists in a single generator when worked to nearly its full capacity.

13. With such proper relations of internal and external resistance the electromotive force will vary but slightly, and the power used will be very nearly proportional to the number of lamps or the current developed.

14. Insulation of conductors and of the armature should be good, and provision made to prevent fire arising from an abnormal increase of current.

15. Means should exist of accurately measuring the current used.

16. A large system should be as economical as a single generator worked nearly to its full capacity, and should be capable of regulation with the same ease.

Much has been said about the sub-division of the electric light and the current, and such sub-division of electricity has been the great bugbear in the distribution of power and light through its medium. This term, while conveying an idea, is in reality essentially wrong. It implies the existence of a current, the expenditure of energy, before the required sub-division of such current is made. We do not wish to sub-divide a current; a current which must be divided before it can be used is not a desirable current.

If we had a reservoir of water dammed up to a certain height, and tap it at the depth, say, of 20 ft., a stream of water will issue proportional to the depth of water and the size of the orifice, and the amount of water flowing in a unit of time will be constant if the height of the water above the outlet be kept the same. By damming up the water we have established a certain potential, but there is no flow of water, no current, and consequently no supply until the orifice is made. Such orifice, aided by the potential of the water, in itself establishes a flow, creates the necessity for a supply. If we make another, a larger outlet, a larger amount of water will issue, and the amount in the first will not be changed if the height of the water remain constant. By opening this second channel we created an additional current, the necessity for a further supply, but such necessity, such flow did not

exist until the creation of the new demand. Our reservoir may be large, our source of supply may be great, but if a sufficient number of openings be made, both reservoir and supply will be fully used, and while expensive for a single channel will be economical for the whole.

So it is in the distribution of electricity. A current is a function not alone of potential, but of potential and resistance. We desire to establish a certain potential, or difference of potentials, and to maintain this so that when a circuit is established, a channel opened, a current may be established in that circuit. We do not divide a current, nor a potential, but having established a difference of potential in two conductors, we open one or more paths, and a current flows over these paths dependent on their resistance, and independent of each other, and such additional current having been formed, the current over the main conductor is increased by just such increment, which increment did not exist until the new path was made. There has been no sub-division of a current: there has been a creation. Such new current having been made, of course more power must be supplied to maintain the existing potential, and while the system may be expensive for a single lamp or motor, when the number of derived circuits becomes sufficiently numerous, it will only be what is required for an economic and efficient supply.

I will now consider the Edison system in the light of the foregoing conclusions. (See page 172.)

CRITICISM OF THE EDISON SYSTEM.

(*Continued from page* 174.)

In the discussion which followed the reading of this paper, Prof. S. Thompson said that while the paper just read embodied a very extensive amount of details and of principles known to electricians, he must say that he was astonished to hear it stated that there was a scientific prejudice against large dynamo machines. He had never met with it, and he believed that the feeling was all the other way. He also did not quite understand what Mr. Sprague meant by "magnets of greater projective powers." The expression was new to him.

Mr. Sprague stated that he simply meant the field power of the magnets.

Mr. Swan rose to express his pleasure at having received such a very full and excellent description of distribution in every detail. He did not feel disposed to take exception to the general principles laid down as to the mode of effecting that distribution. It was certainly done in the simplest way by connecting lamps in arc system. They were certainly now subject to the limitations as to a distance, so distinctly pointed out by Mr. Sprague; but we might emphasise the conditions of such distribution by showing that the difficulties would be lessened by making the filament as fine as possible, so as to obtain the utmost resistance consistent with, say, a 10-candle limit. But when that resistance had been obtained by diminishing the diameter and increasing the length—the light remaining constant—there was still a resistance in the lamp (?) which limited the extent to which distribution might be carried to a lamentably small area—a mile, or something like that. This was a regrettable limitation, but he saw no escape from it with the construction of the lamp. They had a fixed material—carbon—to deal with; they could not alter its specific resistance much, so that they were very much restricted in the extent of their distribution. The only escape from that limitation lay in having secondary batteries at stations or in every house, and in these batteries being connected in series and fed by currents of a higher tension; the principle still holding of multiple arc not from the central station, but from the subsidiary one at which the batteries are charged. Once imagine the possibility of these secondary batteries being maintained at a perfectly constant condition of charge by some automatic arrangement, and we might look to that as a means of escaping from the difficulties of wide distribution. It would only require that each lamp should be provided with an automatic arrangement for maintaining continuity of circuit. Such might be of an exceedingly simple character without adding much to the expense of the lamp. It might be a permanent thing, not to be renewed as often as the lamp, and under such conditions one saw no limit, supposing the lamps could be fed in series to the extent to which distribution might be extended. The only conditions necessary would be the maintenance of the lamps in a condition of equality of light, that the current should be kept constant, and that there should be automatic arrangements for varying the electromotive force at the station in proportion to the number of lights operating, whether one or 1,000. To avoid the use of a very high potential in such a system of feeding in series, the resistance might be very considerably reduced by variation of the internal sectional area of the carbon by using short and flat carbons. He might simply mention the alternative method as a comment upon Mr. Sprague's very positive assertion that they were shut in to the one system of feeding the lamps in multiple arc. He was perfectly ready to allow that that method was the only one in use, except to a very limited extent; but still they must not lose sight of the power of wider distribution which they should obtain by either the entire series feeding of lamps or the use of the series method, with the charging of secondary batteries and there feeding from multiple arc. He felt it was very desirable that they should, by some means or other, see their way to a wider extension, even with all the conditions of low resistance in the armature, which Edison had carried to an extraordinary degree, and high resistance of the carbon. They still had a limited area of distribution, with undue cost. With regard to the dynamos, it was quite an error to say that there was any prejudice as to large dynamos. He had been delighted to see the success of Mr. Edison's efforts in the construction of large dynamos. Mr. Sprague had referred to the use of a shunt current, when less than the whole number of lamps were lighted. It was evident that the same current would pass through the shunt whether few or many lamps were lighted, and evidently the loss would be somewhat greater when only a few lamps were being operated. Reference, too, had been made to the limit to the use of high resistance in the car bon, consequent upon the limit constituted by the tendency of the discharge to take place between the terminals, when there was a great difference of potential between them. That was a difficulty which was to a very considerable extent met by removing the terminals to a great distance, and he did not think that that would be found to constitute a very serious obstacle in the way of an extension of the system.

CORRESPONDENCE.

TO CORRESPONDENTS.

S. A. VARLEY'S CARBON LIGHTNING PROTECTORS.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—I think it might interest some of your readers to know that I have had 110 of S. A. Varley's carbon lightning protectors (which are referred to in the leading article of the ELECTRICAL REVIEW of the 19th instant) in use in connection with Tyer's train signalling instruments for many years, and that I have not had a case where lightning has damaged an instrument to which a carbon protector is connected.

Seventy-three of these protectors were put in use in February, 1867, and thirty-seven in March, 1872.

I am, Sirs,

Yours faithfully,

F. T. J. HAYNES,

Telegraph Engineer and Superintendent,
B. and E. Division, G.W.R.

Taunton, *August 26th*, 1882.

MAGNETIC UNITS.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—As a paragraph in your paper for August 26th, p. 156, headed "Magnetic Units," might possibly lead a casual observer to think that the idea of my instrument was taken from Prof. Silvanus Thompson, in order to show that this is not the case, I wish to quote a few lines from a very kind letter to me from Prof. Thompson. They run thus: "And it will give me much pleasure whenever I do publish an account of my instrument to mention that the same idea occurred independently to you. I have not used the mirror arrangement in connection with my instrument, so that application is exclusively yours."

These few words will, I think, quite do away with what otherwise might introduce an error.

Yours faithfully,

FREDERICK JOHN SMITH.

Taunton, *August 26th*, 1882.

THE TELEPHONE.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Your correspondent "Injustice" says I have "a little more of *law* than of *justice* in my composition." He admits, then, that I have both law and justice in my composition; and I am well pleased with his admission, especially as the statement which I laid down with an "airy authority" is simply a repetition of the decision rendered by Mr. Justice Fry on the law, "that any transmitter combining a diaphragm with a tension-regulator is clearly an infringement of Edison's patent."

The remarks of "Injustice" in regard to Anders' transmitter seem to me to show, on his part, a want of knowledge of the English language, and of its phraseology. My assertion was, "that *any* transmitter combining a diaphragm with a tension-regulator is an infringement of Edison's." I did

not mean to assert that any of the parties named had made a transmitter; but if they or the man in the moon had made a transmitter "combining a diaphragm with a tension-regulator," such a transmitter is an infringement of Edison's, as decided by Mr. Justice Fry and Lord M'Laren. I fail to see the justice of "Injustice" in introducing the Reis transmitter of 1861 into his reply to me, because I made no reference to Reis's instrument. His object, however, is obvious—namely, to ventilate his *opinion* obout the Reis transmitter as being different from the opinions expressed by Sir Frederick Bramwell and other witnesses before Mr. Justice Fry in regard to the Reis transmitter, which, Sir Frederick said, "did not act as a tension-regulator."

Every one has a right to have an opinion on any subject, although he may enjoy a blissful ignorance of that subject. There seems to me to be a wide difference between the importance to be attached to an opinion, and that to the solemn judgment of the High Court of Justice.

In my letter I did not express any *opinion.* I now merely recite the words of the decision of Mr. Justice Fry, who did not think it had been established "that Reis's transmitter combined a diaphragm with a tension-regulator."

I confess that I have a very clear opinion on this matter, but I will not presume to ventilate it in the face of Mr. Justice Fry's decision; but I do express a strong desire that the question will be taken before a higher and the highest court, so that it may be finally settled whether Reis's transmitter of 1861 is an infringement of Edison's of 1877. Perhaps "Injustice" may have embraced the opportunity to pay a *well-merited compliment ! ! !* to the great patentee of patents with hundreds of specific claims for old well-known devices.

JUSTICE.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—With due deference to the "editorial chair" I take leave to say that there is criticism and hypercriticism. To this latter it seems to me that your remark upon my using the words "inductive action" belongs. It must have been evident to you that I quoted these words from Bell's specification, as also from the evidence given by the eminent electrician, Sir Frederick Bramwell, and also that it was necessary for me to use those words to elucidate in a clear manner the claim of Bell, in contradistinction to my claim, and I thereby did not "erroneously consider" "inductive action" to be synonymous with "induction." Inasmuch as eminent electricians and a learned judge have used the term "inductive action," would it be amiss for you to clearly define the distinction between "inductive action" and "induction" for their benefit?

Yours as ever,
W. C. BARNEY.

53, Bernard Street, Russell Square,
August 29th, 1882.

[We were, perhaps, a little unfortunate in attributing to Mr. Barney the words made use of, also in our use of the term "induction," "*direct* inductive action" would, perhaps, have better explained what we meant. The movement of the plate in Mr. Preece's telephonic receiver is certainly caused by "inductive action," although the action is not *direct*. "Inductive action" we take to mean "an action caused by inductive effort." When we speak of the wheel in a steam engine being moved by the action of the piston, we do not mean that there are no cranks or connecting rods between the two. The material of a diaphragm or disc may not in itself be capable of *direct* inductive action, but may be actuated indirectly by inductive action.—EDS. ELEC. REV.]

CITY AND GUILDS OF LONDON INSTITUTE TECHNOLOGICAL EXAMINATIONS, 1882.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—It is with reluctance that I again ask a portion of your space to continue a discussion already outside the range of utility; but there are one or two points which I should like to notice before it is closed.

I would thank "The Student" for his testimony to the value of a theoretical and practical training. I did not for one moment suppose that his knowledge was "examinational," because three years ago I made myself acquainted with the admirable teaching at Cowper Street, and I have no doubt had he been subjected to a *practical* examination his position would have been equally distinguished.

"A. C. S." suggests that my friend's abilities are microscopic. They certainly are not. He is intelligent, familiar with principles which underlie the Duplex, Quadruplex, and other systems of telegraphy, and has on many occasions ably assisted his fellows in their telegraphic studies. He gained a first advanced prize for electricity and magnetism, and has read a good deal. My other friend knows little of mathematics and less of dynamics, and his chemical knowledge has been gained from Preece and Sivewright's "Handbook of Telegraphy."

"Maga" is right when he says there is a great temptation to try for the highest place at once. Our hours are irregular, and we can but ill spare time and money on a study so lightly valued. Our opportunities of acquiring a thorough knowledge are prescribed, as we are prohibited from examining the apparatus we work; there are but few amongst ourselves able and willing to teach "the young idea how to shoot," and when such an one appears for a little are we to be blamed for attempting to reach the goal at a bound? From our superiors we receive, instead of the smile of approbation, the frown of disapproval, and when two or three of us combine for mutual assistance obstacles are put in the way of our meeting. Let the heads of our department announce unequivocally that they desire and will recognise technical knowledge, and for every one who now attends the classes of the Guilds there will be a dozen. "Maga" says, "the questions set for the May examination were specially directed against 'cram,' and no student who had not combined a practical with a theoretical study of the subject could have answered them satisfactorily." For example:—

"Point out the difference between conduction and induction across air in a thunderstorm?"

"To whom are we indebted for the introduction of telegraphy into practical use, and when?"

"Describe the modern system of electrical measurement and detail the different units in use?"

"Describe Bell's telephone and show how speech is reproduced at a distance by its agency?"

Verbum sat sapienti!

This gentleman says, "Your correspondent goes on to state that such a course (theoretical and practical) cannot be gone through at the City and Guilds classes." If he will refer to my letter he will find I did nothing of the kind. I asked "if students more ambitious to win prizes than gain genuine knowledge, and teachers more anxious to increase their incomes than impart lasting instruction, would give to practice the attention it deserves."

The cry of "Aba" about calling in question the quality of his own or *protégé's* knowledge can be appreciated when we know that the particulars of the case cited by me "tally exactly" with those known to him.

Qui se sent galeux se gale!

Nothing has been advanced against my plea for a practical examination to go along with the written one. I believe the day is not far distant when steps will be taken by the City and Guilds Institute to test the progress in practice of those attending their classes, and so still further promote the usefulness of the work they have so well begun.

Yours truly,
FAREHAM.

THE PILSEN-JOEL AND GENERAL ELECTRIC LIGHT COMPANY, LIMITED.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—Your somewhat unfavourable notice of the Pilsen-Joel and General Electric Light Company, Limited, which appears in your current issue, has evidently been written without previous inquiry. I have had the pleasure of showing you over the company's factories since your notic[illegible] was written, and I think you will admit that consider[illegible], progress has been made in the short time that has e[illegible]such since the company was formed, and also that the engin[illegible] flow, [illegible] larger portion of the company's work is satisfactory. [illegible] in the

I have pleasure in informing you th[illegible] the [illegible] constant. mulator, obtained by myself for the company, pr[illegible]current, the a great success; and when the very large pric[illegible] flow did not

companies have paid for accumulators, and the merely nominal price asked by my co-patentee (I having given my share to the company), I think you will also admit the company's prospects are in every way favourable.

I will conclude by reminding you of the many notices of orders and work in hand you have from time to time published in your journal; in the number in which your criticism appears two fresh orders are noticed.

I am, Gentlemen,
Your obedient servant,
HENRY F. JOEL.

August 27th, 1882.

[In reply to our correspondent's letter, which we are pleased to insert, we assure him that our "note" was *not* written without previous inquiry and due consideration. We derived considerable satisfaction from our visit to the Pilsen factories, and can congratulate Mr. Joel on the energetic manner in which the various departments have, under his direction, been planned and fitted up. As far as the factory is concerned no fault can be found, it being a subject rather for praise. We cannot see that the addition of the new accumulator mentioned by our correspondent can affect the prospects of the company in either direction. It would appear that this fresh acquirement is either of little value, or that Mr. Joel has been exceedingly generous. However, engineering work and commercial ability are not synonymous terms. In respect to the latter portion of his letter we will ask: Is it true that Messrs Brindley and Co. have countermanded their orders, or that Messrs. Crisp, of Holloway, have intimated their desire to have the Pilsen-Joel Company's system removed? Is the company in a position to do its own work, or does an intermediate firm influence the company's operations? Perhaps one of the directors could enlighten us on this point. How is it that various concessions have fallen through? For what reasons did the assistant-engineer of the company resign his engagement over the Liverpool installation, and is it a fact that their energetic commercial representative has tendered his resignation? We consider we were quite justified in our "note" on the subject to which our correspondent alludes. In conclusion we may add that we still hold the most favourable opinions as to the merits of the Pilsen-Joel Company's system, and we shall be very pleased to make public any refutation of what we have written if Mr. Joel can show where we have been mistaken.—EDS. ELEC. REV.]

ELECTRIC LIGHT TENDERS.

To the Editors of THE ELECTRICAL REVIEW.

DEAR SIRS,—I feel extremely reluctant to trespass upon your valuable space on a personal matter, but as Mr. James Beattie calls my veracity into question in your last issue, I feel certain that you will do me the kindness to publish my reply.

Mr. Beattie intimates that I publicly made a false statement, knowing the same to be untrue, and it pains me to know that there is a gentleman engaged in the same electrical work as myself who thinks me capable of such a dishonourable course.

Those of your subscribers who read his letter will be interested to know that I emphatically repeat "that the one tender sent in to the Camberwell Vestry was that sent by the Metropolitan Brush Company." Of course I refer to the most recent invitation of the Vestry for electric light tenders on the revised specification as recommended by the committee. Of this invitation Mr. Beattie seems to have been ignorant, and to have left us in possession of the field, though on the first invitation I find that the two tenders sent in were from the Pilsen-Joel and Metropolitan Brush Companies respectively, but a glance at the minutes of the Camberwell Vestry meeting will show Mr. Beattie that "*the one tender*" referred to by Mr. Price at the Metropolitan meeting, in the discussion and in the public [illegible]s, was the one from the Metropolitan Brush Company. [illegible] two earlier tenders, one from us and one it appears [illegible] the Pilsen Company, were treated as entirely out of

Yours faithfully,
R. HAMMOND.

[illegible]non Street, *August 30th*, 1882.

IMPROVEMENTS IN ACCUMULATORS.

[IN our issue of July 29th we took exception to the methods adopted by M. Blanchart in obtaining the results of his tests on electrical accumulators. On the 19th ult. we published a long and interesting letter from that gentleman, to which we now take the opportunity of replying.

To evade a question is not to solve it. It is not a matter of ascertaining whether the capacity of accumulators of equal weight may be increased. No one doubts that. Our *critiques* published in the ELECTRICAL REVIEW of the 29th of July, page 71, only aimed at the method of calculation adopted by M. C. Blanchart, and the facility with which one obtains surprising figures when the art of using them skilfully is acquired. M. Blanchart's letter answers absolutely nothing to these *critiques*. He does not dispute, in fact, that his calculations relative to kilogrammes of *active matter* only take into account the weight of the oxidised plate, and ignore altogether that of the reduced plate, the liquid, and the receptacle. It is, indeed, a convenient mode of obtaining high figures, but it is impossible for us to accept it, for, we repeat, the reduced plate is also active matter, and the idea of ignoring its weight has never occurred until now to any experimentalist.

M. Blanchart protests on the ground that we make him *say* that the electromotive force is constant, which, according to him, is not true. We beg M. Blanchart's pardon, but he has plainly *said* it, and *written* it, adopting in his calculation the formula: $\text{Tr.} = \frac{\text{E I}}{g}$, and taking for E the constant value of 2·15 volts. Was M. Blanchart authorised by previous experiments to take the figure of 2·15 volts as a constant electromotive force? The rapid decrease of a discharge current shows that it is not so and, moreover, the experiments of MM. Joubert, Pothier, and Tresca, have shown a diminution of from 2·165 volts to 2·057 volts, whilst the intensity of the current fell from 16·37 to 11·49 ampères. MM. Gladstone and Tribe have demonstrated also that after thirty minutes of rest or discharge the electromotive force which, in a *freshly charged* battery, is from 2·21 to 2·31 volts, falls to 2 volts, and even to 1·92 volts after forty-five minutes. Are these experiments sufficient to authorise M. Blanchart to accept in his formula a *constant* electromotive force of 2·15 volts?

As to the figures given by M. G. Planté, M. Blanchart neglects to state—what is essential, nevertheless—that if the battery has an electromotive force of from 1·45 to 1·50 Bunsen immediately after the discharge, if this electromotive force be measured *two or three minutes after the interruption of the primary current* (*see* the "Recherches sur l'Electricité," by M. Gaston Planté, p. 75) it is not more than 1·17 Bunsen.

We hold besides, with M. Planté himself, that we cannot count upon an electromotive force higher than 2 volts when the battery is *discharging*.

In conclusion, we maintain absolutely in meaning as in word our *critiques* upon the very original mode of calculation adopted by M. Blanchart, being unable to accept the hypothesis of a *constant* electromotive force in the case of a gradually *decreasing* discharge, and a calculation which, in the attempt to bring forward high results, takes into account as *active matter* only the oxide of lead.—EDS. ELEC. REV.]

THE TELEPHONE.—The United Telephone Company have opened an exchange at Brighton, and active operations have begun. Arrangements for connecting that town with the metropolis, under the powers granted by the Post-office, are now being made.

From Aberdeen we learn that there has been during the past few weeks a great increase in the number of subscribers to the exchange of the National Telephone Company. The desirability of putting the various fire-engine stations in telephone communication with the exchange, is now under the consideration of the fire committee, and should they report favourably arrangements will probably be made for keeping the exchange open always.

From Dundee we receive equally gratifying reports: the Dundee and District Company, and the National Telephone Company, are said to be working hard and adding many subscribers to their exchanges.

NOTES.

EXTENSION OF ELECTRIC RAILWAYS. — A *Post* telegram from Berlin, dated 22nd August, says :—"There is a great increase in the construction of electric railways throughout Germany, their success being established."

THE STEAMSHIP "INTERNATIONAL."—The s.s. *International,* belonging to the India-Rubber, Gutta-Percha, and Telegraph Works Company, returned on Sunday morning, the 27th ult., from Mexico and the West Indies, where she has been engaged in the extension of the Tampico-Brazos Santiago cable to Galveston and afterwards in the repairs of one of the International Ocean Telegraph Company's cables from Key West to Habana.

Both these undertakings were successfully carried out by Mr. Theophilus Smith, engineer-in-charge, assisted by Mr. H. Benest, Mr. J. Rymer Jones, Captain W. F. Wardroper, and others. The repairs of the Key West-Habana cable, however, were effected under the supervision and direction of Mr. M. L. Hellings, cable manager at Key West.

When the *International* has discharged her ballast and docked, she will receive the cable which is now being made at the Silvertown Telegraph Works for the French Government, to be laid along the coast of Tunis, from Soussa to Sphax and from Sphax to Gabes.

THE KEY WEST-HABANA CABLE.—We understand that the Key West-Habana cable of the International Ocean Telegraph Company of New York, which was repaired on July 15th last, had broken down again on the 22nd ult., and that the s.s. *Duchess of Marlborough,* one of the repairing vessels of the West India and Panama Telegraph Company, has been chartered for the purpose.

THE FRENCH ATLANTIC CABLE.—The *Times* says, "On the morning of the 29th ult. the Telegraph Construction and Maintenance Company's steamer *Scotia,* engaged in repairing the French Atlantic cable, put back into Plymouth from the Atlantic the second time in two months. When in May last the *Scotia* left London she had on board some 4,000 tons of cable stored in her immense fore and aft tanks. About 1,000 miles from Brest the cable was connected, and the vessel returned to within 400 miles of Brest to make good "a fault." Upon this work being taken in hand it was found that the American end of the cable was again broken, and testing demonstrated that the accident had occurred 20 miles east of the original breakdown. Buoying the cable, the *Scotia* came on to Plymouth, shipped coals and provisions, and left. The cable off Brest was spliced, and the *Scotia* sought the new fault. This was discovered, but considerable trouble was experienced in the endeavours to repair it. The cable was several times chafed at the bottom and parted, with the result that, after a month's work, affairs remain practically as before. One end is now buoyed ; the other is at the bed of the sea. During the operations 140 miles of cable have been paid out."

FURTHER EXTENSION OF THE NETWORK OF FRENCH CABLES ALONG THE NORTH COAST OF AFRICA.—In our number of the 5th ult. we stated that the India-Rubber, Gutta-Percha, and Telegraph Works Company had contracted with the French Government for the making and laying of 260 nautical miles of submarine cables to connect Soussa with Sphax and Sphax with Gabes. We are now informed that the same company has received a further order for cables to be laid from Gabes to a point on the west coast of the island of Djerba.

The making, &c., of these cables is superintended at the Silvertown Works, on behalf of the French Government, by Messrs. Rambaud and Schaeffer, engineers in the French Telegraph Administration.

Djerba, or Jerbah, is a large level island lying S. by W. ½ W., forty-three miles from Gzira, the western island of the Kerkenah group ; it is about nineteen miles in length east and west, and eighteen north and south, irregular in outline, especially on the southern side, and comprising a coast-line of about eighty-five miles in circumference.

The island is very fertile, with thick plantations of date and olive trees ; upon the coast are several forts ; villages and neat-looking white cottages are scattered over the country. There is a considerable trade in oil, wool, and fruit. Shawls, &c., are manufactured and exported, and there is also a large pottery. The island still produces the lotus, from which it derived one of its ancient names "Lotophaji."

The principal town is Zoug, which has a castle and the singular pyramid of skulls commemorating the defeat by the Turks of some Spanish soldiers under the famous Andrea Doria.

THE ELECTRIC LIGHT.—At the annual three days floral *fête,* which opened in Dundee on Thursday last, the Northern Light Company exhibit one of their systems of electric lighting. At a meeting of the Aberdeen Market Company, held on Friday week, to sign the contract for the restoration of the building which was recently destroyed by fire, it was intimated that the propriety of lighting the new building by electricity was engaging the attention of the directors.

The Highland Railway Company are at present considering proposals from several electric appliance companies to light the Inverness Station, the Station Hotel, the offices, and the company's works by electricity. At a meeting convened by the Ratepayers' Association of Gainsborough, to approve or disapprove of the adoption of the electric light as a street illuminant by the Board of Health, a resolution, "That this meeting, having had an opportunity of judging the capabilities of the electric light and contrasting it with gas, urgently recommend the Local Board of Health to adopt the electric light for lighting the town, if the cost compares favourably with the price paid for gas," was carried *nem. con.* amid loud applause.

On Saturday evening last, the additional lamps, which have been fitted up at the Waverley Railway Station, Edinburgh, were brought into use. So far the light has given the greatest satisfaction and compares advantageously with the experiments conducted twelve months ago on Princes Street. We believe that an application is about to be made to the Town Council for permission to make another series of experiments with the light on the streets.

THE ELECTRIC LIGHT AT COLCHESTER.—Information has reached us that the S. E. Brush Electric Light Company has established a station at Colchester. Owing, however, to some alteration in the driving apparatus being necessary some delay has occurred in bringing the electric light into use at Messrs. E. S. Sanders and Son's establishment, but it is confidently expected to be in operation before the end of the present week. The station is for the supply of the Brush system, and several of the leading firms in the town have expressed their readiness to adopt the electric light as soon as the station is in working order.

THE ELECTRIC LIGHT FOR SNARING FISH.—In our issue of July 15th we published a letter from "DEN[illegible]" suggesting the use of the electric light for attracting fish towards the nets. From France we now learn that [illegible] in the hands of some ingenious Frenchmen, who have lately, by permission of their Government, been experimenting with it, the results obtained have been highly satisfactory. The lamp was contained in an air-tight globe, and was lowered at night into the sea, with the result that thousands of fish of all sizes were attracted to its brilliant light. Boats furnished with nets gradually closed in upon the living mass and made a great haul of fish.

THE JABLOCHKOFF ELECTRIC LIGHT.—Messrs. Shoolbred and Co., of Tottenham Court Road, have now forty lamps in use in their various departments. We understand that Messrs. Shoolbred are satisfied with the financial results.

THE ELECTRIC LIGHTING IN THE BIRMINGHAM TOWN HALL.—Swan incandescent lamps are employed to the number of 496, the electric current being furnished by Bürgin dynamo machines, stationed at the Cambridge Street Works, and connected with the hall by cables laid under-

ground. The greater number of the lamps are arranged on pendant brackets attached to the pilasters which form the leading feature of the structural decoration of the hall, and there are also fifty-two lamps placed in pairs underneath the galleries. These brackets, which are of brass, have a bold, curving sweep outwards and downwards, and then divide into twelve branches. To each branch is attached a small Swan lamp. Along each side of the hall are eight of these brackets, each bearing a cluster of twelve lamps. Over the orchestra there are six double brackets, carrying twenty-four lamps each, while four similar brackets overhang the great gallery. The light thus provided is estimated to be equal to 8,000 candles, as compared with 5,600, which is the power of the ordinary gas illumination of the hall. An engine of 120 horse-power is employed for driving the dynamo-electric machines, there being twelve "Bürgins" of the C type, three being used as excitors for the remainder. We understand that the copper conductor of the cables was manufactured by Messrs. Winfield & Co., of the Cambridge Street Works, and the covering was done by Messrs. Glover, of Manchester. We believe hopes are expressed that the installation may be for a permanency.

THE TELEPHONE IN THE DIVING BELL.—On the suggestion of Mr. H. H. Wake, the engineer to the River Wear Commissioners, says the *Newcastle Chronicle*, the telephone has been applied as a means of signalling between the workmen in the Commissioners' diving bell and the workmen in charge of the crane and air-pump for governing the bell, in the craft employed for submarine work. On Saturday last Mr. A. W. Heaviside, the superintending engineer of the Post-office telegraph system, and Mr. H. H. Wake, made a successful trial at the entrance to the South Dock, Sunderland. The signalling between William Cooper in charge of the diving bell at the bottom of the river and James Miller in charge of the machinery in the craft at the surface was all that could be desired. In fact, everything that proceeds within the bell can be heard above, every stroke of the hammer or whisper of the men. So far as is known, this is the first occasion on which the telephone has been applied to so useful a purpose. It is worthy of remark that in this application of the telephone, which will be exhibited at the forthcoming North-East Coast Marine Exhibition, to be held at the Tynemouth Aquarium, the workmen in the bell have no necessity to speak into the telephone whatever. So long as the telephone is within the bell it records all that is passing."

This is, as our readers are aware, not the first occasion on which the telephone has been applied to the diving bell. In March, 1880 (vide ELECTRICAL REVIEW, Vol. viii., page 125), an experiment similar to the above was made at the Earl Grey Dock, Dundee.

WAR AND SCIENCE.—The Oriental Telephone Company have received from their representative at Alexandria an extract from an official letter to the Admiralty from Admiral Sir Beauchamp Seymour, who writes as follows:—"The telephonic communication which I reported in my previous letter had been established between the *Helicon* and the British Consulate has proved of the utmost value to me since the outbreak of this *émeute*, and inspired the English residents with a certain amount of confidence, as by its means I have been kept constantly aware of the state of affairs generally. In default of this ready means of communication it would have been impossible for some hours to have gained any information from the town except by special messengers, at imminent risk of life."

AN UNPRODUCTIVE TELEGRAPH OFFICE.—Fully twelve months ago, a Postal Telegraph Office was opened at the town of Keiss (Caithness), under a guarantee of £49. We understand that the receipts for telegraph business for the year amounted to the small sum of £24 9s., and consequently the two guarantors have received invitations to jointly contribute £24 11s., that the revenue may sustain no loss.

THE INTERNATIONAL METEOROLOGICAL COMMITTEE.—At he second meeting of this committee, recently held at openhagen, it was resolved to organise an exhibition in connection with the International Fisheries Exhibition, London, of the methods and apparatus used in different countries for giving weather intelligence and storm warnings to the coasts, and of the instruments, &c., used in the study of ocean meteorology. Several resolutions were passed with a view of obtaining greater punctuality and accuracy in the scientific information furnished to the committee. M. Tietjens, chairman of the Great Northern Telegraph Company, submitted a plan for a cable to connect Iceland and the Faroes with Europe, the expense to be met by the receipts from Meteorological telegrams. The committee, while recognising the very great importance which information got from Iceland and the Faroes must possess in relation to the issue of storm warnings and forecasts in Europe, felt they were not in a position to express an opinion on the practical execution of the project.

ON THE THEORY OF THE VOLTAIC BATTERY.—By G. Cantoni.—The author observes, in the first place, that the proposition of the co-existence of several movements can be used as the foundation of the reciprocal magnetic and electric inductions. He remarks, however, that if we regard bodies as composed of bipolar elements, each of which exerts two equal and opposite inductions, and if we contemplate a series of n such elements, the action upon the poles of each element of the series will be derived from the joint action of the poles, and of that induced by the homologous poles of the other elements. If m expresses the order of an element, p, of the series, the sum of the internal inducing actions of its poles will be $m + n - (m - 1)$; where the effects, m, have an opposite sign to those, $n - (m - 1)$; further, if p' is the element as far remote from the central position as p, the sum of the internal inducing actions of its poles will also be $m + n - (m - 1)$, where likewise the actions, m, are of opposite signs from $n - (m - 1)$. For the element, p', the effects, n, and $n - (m - 1)$, are of opposite signs to the effects, m, and $m - (m - 1)$, of the element, p. The algebraic sum of the inductive actions of each pair of elements, equidistant from the middle point of the series is, therefore, $= 0$; the action of the n elements of the series is also null; and that of the central element, or the central pair of elements, is null; whence follows the neutral line of the system. Since further, $m + n - (m - 1) = n + 1$, and is, therefore, independent of m, the sum of the inducing effects is constant for each element of the series.

If we approach to one pole, b, of an insulated electric element, a, b, an inducing ball, a', connected with the ground at a very small distance, and in a perfectly insulating medium, the end, a, of the ball displays, in consequence of the induced action of b, an equal and opposite inducing action upon b, so that the outward action of the other pole, a, is doubled. This corresponds to the impulse experiments performed with a series of balls of equal mass suspended in succession. Quite analogous is the composition of the inducing actions in coated insulators.

The author further compares such an insulator with a battery, and remarks, that if in the former the two poles are several times connected by a conductor, we obtain a series of discharges of decreasing intensity; whilst in a battery all the sparks are equally strong, since the heat evolved in the battery by chemical activity affords a constant source of energy. The succession of sparks represents the current.

Further observations refer to the fact that the current does not increase infinitely in a battery.

The author further discusses the thermic, chemical, and electrical phenomena which appear in a voltaic battery, amidst the reciprocal action of heterogeneous solids and liquids, whereby the intimate relations between the quantities of heat contained in the bodies, their combining weights and combination heat, but which do not appear in the open battery.

The author finally remarks, that Ohm's formula treats of the cause of the production of the electromotive force, whilst Faraday's and Joule's laws present equivalences between the values which appear in the current. He therefore considers the latter more essential than the former.—*Wiedemann's Beiblätter.*

ON THE ELECTRICITY OF FLAME.—By Julius Elster and Hans Geitel.—Concerning thé electricity of flame there

exists a great mass of researches which contradict each other in several respects, both as to the results and as to the views put forward by different authors on the cause of the electricity of flame. The origin of the electric difference may find its explanation in the following three causes:—The electricity of flame is determined by the combustion process as such (Pouillet, Hankel). It is caused by the flame behaving as an electrolyte to the metals introduced as electrodes (Matteucci). It depends on a thermo-electric difference of the electrodes.

The authors have come to the following experimental results:—

1. The longitudinal polarisation of the flame is only apparent, and is elicited by the unequal introduction of the wires which serve as electrodes.

2. The flame evinces in its transverse section a strong electric polarisation, and the electrode which is plunged into the stratum of air immediately enveloping the flame is always positive towards the electrode which enters the flame itself.

3. The electromotive force does not depend on the size of the flame.

4. The change of polarity of the flame may be produced by a suitable displacement of the electrodes.

5. The electromotive force of the flame depends on the nature of the metals employed as electrodes and on the nature of the gases consumed. It is especially strong if aluminium or magnesium is used as a conductive metal, and especially weak if the electrode in the air is coated with salts, *e.g.* chloride of potassium.

6. By employing electrodes of water and excluding all metals indubitable electric effects of flame may be also obtained, the electrode in the air being always positive to that in the flame.

7. Flames may be combined after the manner of galvanic elements, thus forming a "flame-battery."

The magnitude and kind of the electric excitement are independent of the size of the flame, but depend on the nature and the superficial condition of the electrodes, on the nature of the burning gases, and on the state of ignition of the electrodes. The authors infer that Hankel's theory is not in harmony with the facts, whilst the kinds of excitation assumed by Buff and Matteucci may be regarded as simultaneously determining the apparent electricity of flame.—*Annalen der Physik und Chemie.*

On the Action of Tension upon the Electric Resistance of Copper and Brass Wires.—The wires were stretched in a tin-plate cylinder, filled with water, 913 mm. in height and 192 mm. in diameter. The displacement of the marks on altering the tension could be observed through box-shaped expansions, closed with glass plates. The corresponding changes of resistance were measured by means of Jacobi's rheostats. The most careful observation was made on three brass wires taken from the same original piece, and drawn successively thinner and thinner. The wire contained 63·66 per cent. of copper, the rest being almost exclusively zinc. In order to find the change of the specific resistance, the co-efficient of elasticity, E, and the co-efficient of torsion, C, were determined in kilos., and thus $\mu = (E/2\ C)\ 4 - 1$ was calculated. If σ is the experimentally determined proportion of the relative change of resistance to the relative change of length, $\sigma' = \sigma - (1 + 2\ \mu)$ represents the proportion of the change of the relative specific resistance to the relative change of length. In the three wires, with the respective thickness of 0·91, 0·79, 0·46 mm., the co-efficients of elasticity and torsion of which became successively smaller, and the absolute electric resistance became greater, the ratio σ'' of the change of relative specific resistance to the relative change of length, increased from 0·298 to 0·316 and 0·415. The mean value of $\sigma'' = 0·342$.—*Mél. Phys. de St-Pétersbourg.*

On Systems of Electric Recipients consisting of Chains.—By A. Jedlik.—Barometer tubes closed at one end before the lamp, 66 c.m. in length and 10 to 12 in diameter, are filled to the height of 30 c.m. with fine iron filings, coated without with tin-foil opposite the filings, and the free service covered with shellac varnish. A copper wire plunging into the filings leads outwards. Several tubes are set in a glass cylinder, which is closed above and below, with hollow brass globes or tin capsules, the one in contact with the copper wires and the other with the tin-foil coatings. In this manner they are connected as a battery. The surface of this battery is relatively large; there is no fear of an over-stroke over the broad uncoated margin, and it takes up little room.

A number of such tube batteries may be placed together horizontally or perpendicularly upon insulating feet, and may be connected either laterally or in succession. A Lane's jar, connected with the coating, which discharges itself at a certain charge of the battery, prevents the perforation of the glass tubes.

With a cascade-battery of four such elements the striking distance, under favourable conditions, is 30 to 40 c.m., and is nearly proportionate to the number of the elements. Between two wires, cemented into a glass tube with sealing-wax, the spark travelled along the surface of the tube for 90 c.m., whilst its striking distance in the air, in the latter case, was only 18 c.m.—*Wiedemann's Beiblätter.*

Improvements in Electric Batteries.—Conical vessels containing the funnel-shaped electrodes, and each having below a supporting block, are inserted in each other. If the elements are to contain two liquids they are separated by funnels of felt. For secondary batteries the vessels are formed of lead, their two surfaces serving respectively as positive and negative electrodes.—*Wiedemann's Beiblätter.*

Geissler's Tubes with Vapours.—By K. Krajewitsch.—The same series of luminous phenomena which is observed in Geissler's tubes, by increasing rarefication of the air is perceived; also if the tube is filled with saturated watery vapour, and is then gradually cooled more and more in a freezing mixture. If mercurial vapour is used instead of watery vapour, the tube gives no discharge at common temperatures, but if it is heated stratification appears.—*Jour. Russ. Phys. Chem. Gesell.*

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

1881.

5688. "Cymaphens or apparatus for transmitting sound by electricity." C. F. VARLEY and F. H. VARLEY. Dated December 27. 10d. The first part of the invention may be described as a diaphragm microphone. Fig. 1 represents one arrangement of this invention. On the end of the style, E, there is an adjusting nut for regulating the pressure spring, *b*, which is made to press the cross bar, *a*, against the contact pieces, *c*, c^1. To cross bar, *a*, an armature, *f*, made of

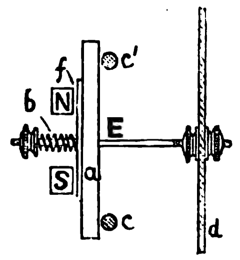

FIG. 1.

iron or other suitable magnetic metal is attached. Near to this armature the poles, N and S, of an adjustible magnet are placed; these poles attract the armature and counteract the force of the spring, *b*. It is obvious that if the magnet is of sufficient force, it would overcome the pressure of the spring, *b*, and open the circuit between *c* and c^1—if the space between armature, *f*, and the poles, N and S, be increased the magnetic force is weakened, and the spring, *b*, forces the cross bar, *a*, into contact with *c* and c^1,—thus by regulating the distance of the magnet *n. s.* and the force of the spring, *b*, any degree of contact pressure can be produced, and the most sensitive condition for transmitting sound by means of electric waves obtained. Fig. 2 shows a simple method of producing the augmentation of the variation of the current. To the diaphragm, D, is attached an iron crook, C, making contact with C^1, which latter is adjustible. The current

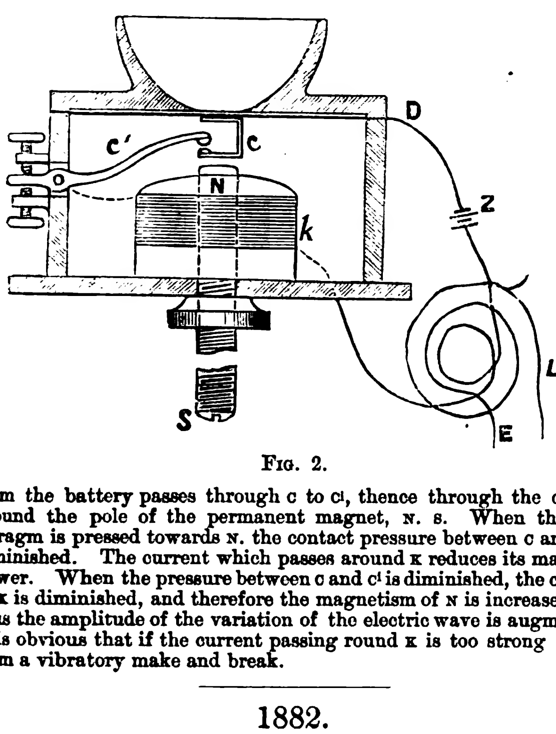

FIG. 2.

from the battery passes through C to C^1, thence through the coil, K, around the pole of the permanent magnet, N. S. When the diaphragm is pressed towards N. the contact pressure between C and C_1 is diminished. The current which passes around K reduces its magnetic power. When the pressure between C and C^1 is diminished, the current in K is diminished, and therefore the magnetism of N is increased, and thus the amplitude of the variation of the electric wave is augmented. It is obvious that if the current passing round K is too strong it will form a vibratory make and break.

1882.

130. "Machinery for obtaining, transmitting, and applying electric currents for lighting, &c." W. T. HENLEY. Dated January 10. 1s. 6d. Relates chiefly to dynamo machines similar in general construction to those described in the number of the Review for August 1st, 1881.

305. "Electric lamps." J. N. ARONSON. Dated January 21. 6d. An incandescence electric lamp, according to this invention, is constructed with a globe or translucent containing vessel having one or more reflectors formed in, on, or with the material of such globe or vessel itself. The reflective surface may be produced by silvering, painting, gilding, or enamelling the material of the globe or vessel either inside or out, or by shaping the globe or vessel so that it shall form one or more dioptric or cata-dioptric lenses or prisms.

346. "Electric lamps, &c." R. E. B. CROMPTON. Dated January 24. 8d. Relates to improvements in the inventor's well-known arc lamp.

358. "Sounding apparatus." C. A. MCEVOY. Dated January 24. 2d. The improved sounding apparatus operates by completing an electric circuit when it comes into contact with the bottom. (*Provisional only.*)

CITY NOTES.

OLD BROAD STREET.

THE GÜLCHER ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

ON Wednesday morning the first ordinary general meeting of the shareholders of the above-named company was held at the Cannon Street Hotel under the presidency of Mr. John Blundell, chairman of the company.

The secretary, Mr. C. B. Charlewood, having read the notice convening the meeting,

The Chairman said: Gentlemen, this you are aware is called the statutory meeting of the company held, by the requirements of the Act of Parliament, four months after the registration of the company, which took place on May 1st. It is not usual at such a meeting to go into detail or formal business, but we have simply now to tell you how far we have progressed with this company. You are aware that the company only started in May, and therefore there has not yet been much time to do anything, but the secretary will read to you a report of the business done so far as it has gone. I can assure you everything is as satisfactory as it can be. This time of year is not the best for bringing out subsidiary companies, and we have, therefore, deferred putting forward several that we have in hand until November.

The secretary then read the following report:—

The company was incorporated on the 1st May last, and the first allotment of shares was made on the 10th of the same month. The total number of shares that have been applied for is 28,147, of which number 27,937 have been allotted to 307 shareholders, leaving a balance of 2,063 to be taken up before a quotation on the Stock Exchange can be obtained. On the 16th June an agreement was entered into with Mr. William Crookes, F.R.S., by which the company undertook to purchase his incandescent lamp upon very favourable terms. The directors congratulate the shareholders upon having acquired this light, as an incandescent lamp is indispensable for household lighting, and they consider Mr. Crookes's lamp by far the most perfect invented, both as regards durability and economy. The directors have also the pleasure to announce that Mr. Crookes has accepted a seat on the board, and they feel assured that the company cannot but derive great benefit from the services and advice of such an experienced and well-known electrician. The directors beg to announce that they have disposed of a concession for the sale of Gülcher dynamos and lamps in Scotland, and that they are negotiating for the sale of further concessions for districts and towns. The Gülcher light was exhibited at the fêtes of the Royal Horticultural and Botanic Societies, and was very much admired both for its brilliancy, steadiness, and softness; and H.R.H. the Duchess of Teck, on the occasion of the *fête* at the Botanical Gardens, sent for Mr. Gülcher and congratulated him upon the success of his light. Messrs. Ransome, Josselyn, and Woods, of Battersea Foundry, who are manufacturing dynamos and lamps for the Gülcher Company, have, of course, had great difficulties to contend with at first, as, with the exception of Mr. Gülcher and his foreman, the work was comparatively new to all; but the directors are happy now to be in a position to announce that these difficulties have been successfully overcome, and that dynamos are being manufactured at Battersea which Mr. Gülcher pronounces to be perfect in every respect. Lamps of various candle-power are also being manufactured. A special factory has been constructed at Battersea for the manufacture of Crookes's incandescent lamps, where they are now being made, and in a short time it is expected that they will be turned out at the rate of over one thousand per week. The directors are happy to say that they have numerous orders in hand for installations from various parts of the country, and that the plant for the execution of these orders will be delivered during the course of the next month. They are also negotiating with subscribers to hire the light from two large centres; the net income from one of which alone will be from £5,000 to £6,000 per annum, and the second centre referred to is likely to be on quite as large a scale. The directors have decided to send exhibits to the North East Coast Exhibition, to be held at Tynemouth, commencing on the 6th September; to the Crystal Palace Electrical Exhibition, commencing in October next, and also to the Royal Aquarium Electrical Exhibition, to be held during the coming winter. The directors have the pleasure of stating that arrangements have been come to between the company and one of the most influential firms in New Zealand to represent them there as their agents; and they expect shortly to conclude a similar arrangement with another eminent firm for representation in India. Both these agencies are likely to result in the formation of large branch companies in these colonies. The directors think that they may congratulate the shareholders upon the prospects for the future of the company being most promising, and they look forward to the shares of the company rising considerably in value at no far distant date.

The Chairman said: Having heard this report, gentlemen, I have very few words to say in addition to it. I am not aware that it is usual to move the adoption of such a report, it is issued for the benefit and for the information of the shareholders. The directors are quite confident that the company is likely to prove a successful one, but, of course, it requires time. You have all read the report of Dr. Siemens at Southampton, in which he says electric light is undoubtedly the light of the future. As regards the arc light for factories and the incandescent light for mines, there is no doubt that the electric light is the light of the future. We have every advantage. We have made the best terms possible with Messrs. Ransome, who are very large manufacturers; and by making terms with them we have been able to save an expenditure of capital, which has not been the case in other companies. Of course you are aware that making dynamos, which are new,

requires considerable time. Even during the last two months, Messrs. Ransome have turned out several very valuable machines. I think the Brush Company were some considerable period before they turned out any good machines; and therefore so far, I think, we may congratulate ourselves on being very successful. As regards Mr. Crookes' lamp, it is the best yet produced, and we have purchased it on very favourable terms. Mr. Wm. Crookes, who is one of the first electricians in the country, has become a member of our board; and no doubt his addition to the board is a very great acquisition, as he at all times is ready at hand to give us his valuable advice. It will be, of course, to our interest to keep down expenses and to carry on the company in the best way that we can. With regard to concessions, there is no doubt we should have been more successful were it not owing to the state of affairs in the East. There has been a scare in the money market; but the fact that one gentleman has put down £1,000 on deposit for the Scotch concession is a proof of its *bona fides*. Another concession has fallen through, and I think it is a good job that it has, for the terms were not the most favourable to this company. We have still that part of the country to deal with. I think, gentlemen, I have no further information to give you now. I hope next time we meet I shall be able to report most successfully of the company. The information we now give is given voluntarily, for the sake of the shareholders.

Mr. Briers asked whether the board had yet given consideration to secondary batteries.

The Chairman said they had under consideration a new secondary battery, said to be very successful and cheap. It was at Messrs. Ransome's works, Battersea, and was being tested now. Of course these things required very great consideration. Enormous prices were asked for these different patents. Several patents had been offered them by one person and another; but the one they were now testing they were told was the best, so that they would then have the best arc lamp, the best incandescent lamp, and, they hoped, the best accumulator. Mr. Gülcher was present, and he had much pleasure in introducing him to the shareholders. That gentleman had done his best to meet their requirements; they had engaged his services for a time in order that he might be able to help them to realise their wishes. They were really very much indebted to Mr. Gülcher for the interest he had thrown into the concern.

Mr. R. J. Gülcher remarked that he was convinced that his system of electric lighting was a good one. As he had done his best in the past, so he promised to do in the future. He hoped the meeting would excuse him from saying more, as he was an indifferent public speaker.

The Chairman said if any other gentleman had any further question to ask in connection with the company, he should have pleasure in answering him.

After a pause, and no further question being asked,

Mr. Cornell said, as no question was asked, he should be happy to move a vote of thanks to the Chairman, and also to the directors.

Mr. Briers seconded, and the motion was carried unanimously.

MEDITERRANEAN EXTENSION TELEGRAPH COMPANY, LIMITED.

On Thursday morning, under the presidency of Sir James Carmichael (Chairman of the company), the fiftieth ordinary half-yearly general meeting of the shareholders of the above undertaking was held at Cannon Street Hotel.

The notice convening the meeting having been read by the secretary, Mr. Edward Tombs,

The Chairman said: Gentlemen, the report and accounts have been distributed and circulated amongst you several days, will you take them as read? ("Take them as read.") Well, gentlemen, in moving the adoption of the report and accounts which have been submitted to you, I would merely draw your attention to the fact that the result of our working has been so far satisfactory as to show a slight increase in the traffic for the past half-year, and this notwithstanding the interruption for upwards of two months of the Corfu-Otranto cable. With regard to that interruption I may say that the repairs to the cable were conducted in the most satisfactory manner. We were, unfortunately, unable to obtain any steamer in the Mediterranean with proper apparatus for doing that kind of work, so we chartered one of Messrs. Headley & Co. She called at Malta and took on board the spare cable, and then proceeded to Otranto to repair the damage. The vessel was a little delayed by bad weather, but when she did begin the repairs only occupied twelve hours, and we only used one and a half miles of new cable. There is another satisfactory matter in connection with these repairs—that is the admirable state in which we found the cable close to where this accident occurred. That cable was laid in 1859, twenty-three years ago. And it reflects great credit on Messrs. Glass, Elliott & Co. that that cable should have come up so well after lying down so many years. This is particularly encouraging to us, because the other cable, from Malta to Sicily, was laid ten years later on—in 1869—and, of course, even so much the better must the one now be than the other. That is an encouraging fact to bring under your notice. You will remember that this time last year negotiations were entered into with another company for the purchase of this company's business, but those negotiations then fell through. They have been renewed again, but I am not at the present time in a position to lay any definite offer before you. What I should propose would be, if anything should come out of them which we think it is desirable to adopt—for the board to recommend to you—to call a special meeting for the purpose; it might be later on in the autumn. With regard to the death of our lamented friend, Mr. [Gur]ney, who has been connected with this company as director since [e]arly formation, I am sure you will with myself and others feel [muc]h sympathy. I have now to propose the adoption of the report [and] accounts.

Mr. Attwell seconded the motion.

Mr. Crafter: Do we understand that before you conclude any definite arrangement with the new company to take over these lines you will call a meeting of our shareholders?

The Chairman: Most decidedly. We have no power to do that without consulting the shareholders.

Mr. J. Hengler (Liverpool): When does the Government subsidy expire?

The Chairman: In December next, at the end of the present year.

A Shareholder: Then really there will be no more dividends?

Mr. Crafter: You will go on working with the £12,000 reserve fund?

Another Shareholder: You have no dilapidated cables now?

The Chairman: No.

Mr. Vears thought the company could make hay while the sun shines. He came in to the meeting rather late, and, although he did not want to be troublesome, he should like to ask if the chairman would be so kind as to go out of his course and tell the meeting whether anything likely to be substantial would probably come out of the negotiations going on? Was there anything upon which the shareholders might base their hopes in this matter? The simple negation, "We cannot tell you anything" led one to ask, "What can you tell us? Tell us whatever of good you can."

The Chairman replied that of course Mr. Vears was aware that in business matters it was sometimes very injurious and damaging in stating anything until a definite arrangement had been arrived at. He did not think he could go any further than he had.

Mr. Crafter: The negotiations are still going on?

The Chairman: Yes, sir; they are not stopped.

A Shareholder: Suppose these negotiations fall through, what will be our position then?

The Chairman: You will have to depend upon the earnings of the company.

Mr. Vears remarked that he did not like the idea of no dividend at all. If they could not pay their present dividend he thought perhaps they might be able to pay 1½ on the company's earnings.

A Shareholder: What is the subvention from the Government?

The Chairman: The total subvention from the Government was £2,700 a year; the half of that sum has been the average we have received from them since the starting of the company. We have not had occasion to ask the Government for all of it. We have taken the whole of it, thus, on account of our repairs.

Mr. Crafter: Is this the last dividend we shall have?

The Chairman: The subvention does not expire till the end of the year.

A shareholder asked whether, as the £12,000 in hand was in Consols, and earning only 3 per cent., the board had power to invest that money in preference shares and so earn 8 per cent.?

The Chairman: We have no power to invest our £12,000 in preference shares.

Mr. Hedley said he should like to congratulate the shareholders on the satisfactory statement made by their chairman as to the duration of their cable. The one now repaired they were told had been down twenty-three years; and therefore he thought the old theory of the ten years' life of cables was exploded.

The Chairman: Yes; they are to be congratulated.

The Chairman then put the motion for the adoption of the report, which, having been seconded, was carried unanimously.

Mr. Beart then moved the re-election of the retiring directors—Sir James Carmichael, Bart., and the Hon. Ashley Ponsonby.

Mr. Vears seconded, and the motion was carried.

In reply to a question as to whether the board intended to fill the vacancy caused by Mr. Gurney's death,

The Chairman said they had not yet decided to do so; but when they did—perhaps at the next meeting—the nomination would be submitted to the shareholders.

A Shareholder thought three directors on the board was very few.

Mr. Crafter was of opinion that three could satisfactorily manage the concern.

A proposition for the re-election of Messrs. W. E. Allright and W. G. Hayward as auditors having been seconded, the motion was put and carried.

The Chairman: I have next to propose payment of the usual dividend at the rate of 8 per cent. per annum, less income-tax, on the company's preference stock, and at the rate of 3 per cent. per annum free of income-tax on its ordinary stock, payable on and after the 7th proximo. The proposition having been seconded, was carried unanimously; and, on the proposition of Mr. Field, a vote of thanks to the chairman concluded the business of the meeting.

SIR W. THOMSON'S RECORDERS FOR SUBMARINE CABLES.—We read in the *Operator* that the French Government is going to adopt Sir William Thomson's recorder as a means of correspondence on its cables between Marseilles and Algiers. These cables are at present worked by means of the mirror galvanometer. Six recording instruments are now in course of construction for the French Administration of Telegraphs at Mr. White's, of Glasgow, who is the only manufacturer of Sir William Thomson's recorders. It is expected that the instruments will be in full operation by the month of August next. A select party of operators are now undergoing a course of lectures and tuition in the use of the recorder in the rooms and under the supervision of Mr. Ternant, director of the Eastern Telegraph Company, at Marseilles. The latter company has employed the recording instrument from the commencement.

THE TELEGRAPHIC JOURNAL AND

Electrical Review.

VOL. XI.—No. 250.

ELECTRIC LIGHTING ON A LARGE SCALE.

OUR readers are for the most part fully acquainted with the electric lighting operations of the Edison Company on the Holborn Viaduct, with the additional extension of the system to the General Post-office. This is the most complete and best appointed arrangement of incandescent electric lighting yet seen in this country, and satisfactorily proves that its adaptation on as extensive a scale as gas is chiefly a question of first cost. We notice in the *Standard* of last Wednesday that its correspondent telegraphs as follows :—

NEW YORK, TUESDAY NIGHT.

Mr. Edison's system of providing an incandescent electric light for domestic use in a given district has just been put to a practical test in this city. The district selected occupies an area of nearly a square mile. Only one source of supply is provided, and that furnishes the illuminating power for sixteen thousand lamps, the electric current passing through 18 miles of mains. The result is that the severest demands which the consumers have been able to make upon the new system have been satisfied.

The *New York Herald* is using in its business premises an isolated plant on the same principle; and the managers assure me that they are satisfied in respect to the commercial aspect of the question.

No new obstacle has presented itself to the success in practice of Mr. Edison's theory; and scientific men will be interested to know that this first practical experiment demonstrates the soundness of the inventor's application of the multiple arc system, pure and simple, as distinguished from the series system, or the combination of the arc and series systems.

Throughout the entire district lighted as described, each lamp was independent of all the others. On the inquiry before the Select Commission of the British House of Commons, Dr. Siemens said it was impossible to supply electricity for domestic lighting from one source over a greater area than a square quarter of a mile. Last night, although only five thousand lamps were lighted, they were distributed over the entire district of the square mile. In the district there are fifteen hundred consumers of gas, of whom eleven hundred have subscribed for the electric light.

In the *Scientific American*, of August 26th, is to be found an illustrated description of this great installation of the Edison system, which varies in some details from the above. Additions, however, have probably been made since our contemporary's article was written. The district includes, according to our American authority, 946 consumers, and the number of lamps operated in connection with this scheme amount to no less than 14,311. Amongst the many interesting items forming part of this extensive undertaking we will merely allude to several of the most important. The Babcock and Wilson boilers are four in number, and can supply 250 horse-power each, and the electric current is produced by six of Edison's largest dynamo-electric machines. Each machine weighs complete (engine, dynamo, and base) 62,000 lbs. The field magnets weigh 33,000 lbs., and the armature 9,800 lbs. The length of this latter is 61, and its diameter 27·8, inches. The height of the machine from floor to top of field magnets is [illegible] ft. 4 in. The nominal capacity of each dynamo-electric machine is the production of 1,200 lights of 16 candle-power each; but at their maximum it is stated they can each produce 50 per cent. in excess of this.

The current from all the machines is centred in two large copper bars with which the several street conductors are connected, and if from any cause it is supposed that one of the machines is not doing its work properly, it can be instantly disconnected from the rest by a huge switch which cuts it off from the main conductors. The presumably faulty machine is then joined up to 1,000 test lamps of 16 candle-power each, and if the current produced by the machine brings these lamps to brilliant incandescence, it is in usable condition. Of course if this desirable result is not attained the existing fault must be sought for by other means. The size of the conductors varies with the requirements, those in the street are equal to a copper rod of one-half inch in diameter, and the service conductors differ, some being equal to two, and others to ten, No. 10 wires. The street conductors are something over 14 miles in length. The field-magnets of the dynamos are placed in a shunt circuit derived from the main circuit, which includes a switch and a number of rheostat coils, one or more of which may be thrown into the shunt circuit, so as to add to the resistance of the shunt circuit from a small fraction of an ohm to seven and a half ohms, which is the greatest resistance necessary to control the current exciting the field-magnets, and thus control the current in the main circuit.

There is a set of resistance coils for each dynamo, each set being provided with a circular switch, operated by a horizontal shaft through sets of mitre gearing. An attendant is stationed at the wheel at the end of the horizontal shaft, and turns the switches one way or the other, according to the requirements. He is able to judge of the amount of current required by watching an indicator above the regulator. This indicator is provided with two lamps, one red and one blue, and with a device for throwing one or the other of them into the circuit, according as the current is strong or weak; and neither lamp is illuminated when the current is normal. When the blue lamp is lit more resistance is required in the shunt circuit to reduce the amount of current passing through the wires of the field magnets, consequently the attendant turns the switch, throwing in one coil after another until the blue lamp ceases to shine. When the red lamp shines, the switch must be turned in the opposite direction to increase the power of the field magnet and to strengthen the current in the main circuit.

We believe the *Standard* correspondent is in error concerning the remarks he ascribes to Dr. Siemens. He merely suggested that one-fourth of a square mile would be a proper or convenient area to work from a centre, and we need scarcely remind the author of the telegram from which we quote that Dr. Siemens knows as well as Mr. Edison exactly what electricity *can* be made to do.

We have said sufficient to show the vastness and importance of this enterprise which appears likely to be a perfect success, and it is to be hoped that when the results of the Holborn Viaduct experiments are known they may be of such a nature as to induce London to follow the example of New York. Success in America will doubtless have a lively and beneficial effect upon electric lighting industries in England, which are apparently depressed for the moment.

THE LEVETT-MÜLLER ELECTRIC LIGHTING SYSTEM AND MULTIPLE CIRCUIT DYNAMO.

[We extract from the *Scientific American* the following description of a system of electric lighting which we think new to our readers.]

THE dynamo, which is shown in perspective in fig. 1 and in transverse section in fig. 2, is capable of yielding a number of separate and distinct currents, which may be employed in widely different kinds of work. The dynamo shown in the illustration furnishes four separate circuits, with electric currents for as many different uses. One current is used for the arc light, another for incandescent lights, another for the transmission of power, another for 'plating. By simply duplicating some of the parts of chine, the number of different circuits supplied may finitely extended, and the currents may be used ngeably for the arc lights, incandescent lights, electric motors, electroplating, storage of electricity, ore separating, and in fact for any of the purposes to which electricity is applied. The production of a number of separate and distinct currents in one machine is a novel feature claimed by Mr. Müller, and one that is of great utility. For example, by using one of these machines a hotel may have arc lights in the halls, offices, and in front, while its parlours and private rooms may be supplied with incandescent lights, and power may be furnished for its various operations of the kitchen and laundry. Similarly, public and business buildings and private dwellings may be equipped, and steamers may be provided with arc lights for the decks and head lights, while the state rooms and cabins may be provided with the softer and mellower incandescent light.

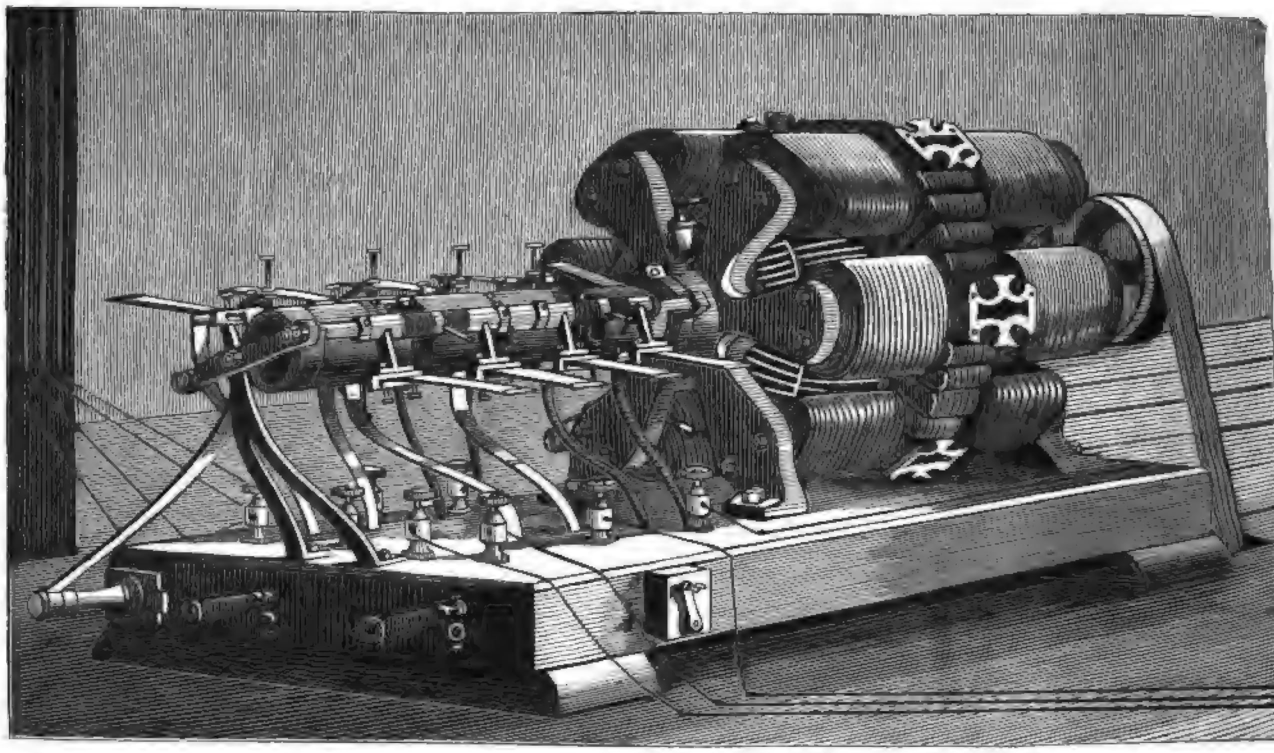

FIG. 1.

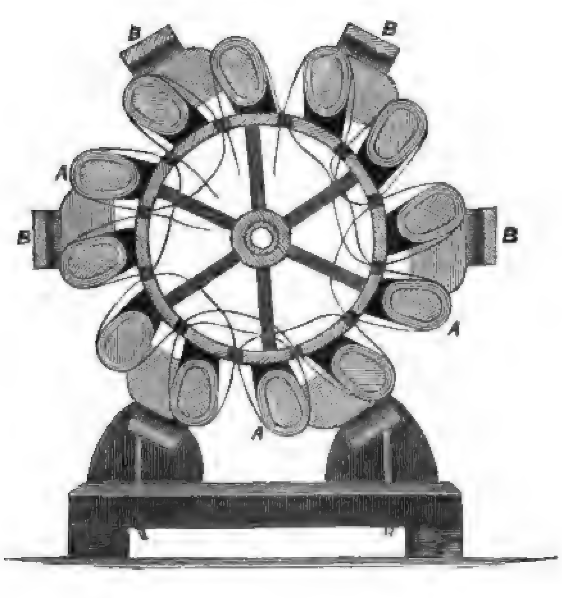

FIG. 2.

This desirable result is secured by employing a series of armature coils or bobbins, A, in an armature wheel rotating between the poles of two powerful multi-polar field magnets, B, the several bobbins being divided into series, each series being connected with a series of commutator bars, forming commutator cylinders, each being provided with a pair of collecting brushes, which deliver the current to the circuit upon which it is used.

To economise power the bobbins of the armature are arranged so that they are diagonal in relation to the poles of the field magnet. This plan allows the bobbins of the armatures to be removed from the vicinity poles of the field magnets with less force than would be required were the bobbins exactly radial.

The peculiar form of the armature wheel insures another important result—that is, the creation of a current of air throughout the machine, which keeps all of the parts cool.

The arrangement of the field magnets, armature bobbins, and connections is such that no bad effects are experienced from induction, the current in one circuit having absolutely no appreciable effect on that of another circuit.

This machine in ordinary working makes about seven or eight hundred revolutions a minute, and the lamps supplied by it seem to burn with absolute steadiness.

The arc lamp invented by Mr. Müller has a novel air check, which regulates the movement of the upper carbon. This, in connection with other new devices, renders the light very steady indeed. One form, which is shown partly in section in fig. 3, is of the same general construction as those burning single pairs of carbons, but made in duplicate, so at it will burn two, three, four, or more pairs of carbons in succession.

In this lamp, when the electric-arc is very small, there is very little resistance in the circuit, and the helix draws its core inward, raising the free end of the lever, A, as far as the upper screw will permit. This causes a pawl to engage with the ratchet-wheel of the feeding mechanism, which is rotated a short distance in the proper direction to raise the positive-carbon holder and lower the negative-carbon holder, thus separating the carbon points. This operation is repeated every time the carbons approach each other too much. The rapid descent of the carbons is prevented by

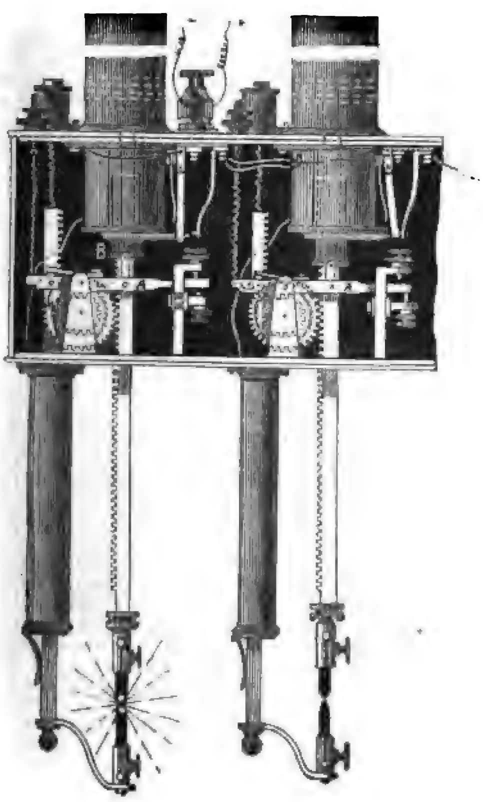

FIG. 3.

the piston attached to the upper or positive-carbon holder. The weight of the upper carbon and its holder, acting on the ratchet-wheel and its shaft, raises the lower carbon holder. As the positive carbon is consumed twice as rapidly as the negative carbon, the wheel which it moves must have twice the diameter of the wheel which moves the negative carbon. As long as there are any carbons in the first lamp, the current passes into the positive-carbon holder, the positive and negative carbons, the helix, the joint piece of the armature, and from there to the generator. During this time the armature at the side of the helix is attracted by the pole piece at the lower end of the helix. As soon as the first set of carbons is consumed to such an extent as to interrupt the circuit, the side armature is released from the pole-piece, and is pressed against a contact-strip which sends the current through the second set of carbons. As soon as the second set of carbons is consumed the armature of that lamp is released in the same way, sending the current to the third set, and so on.

It will be seen that by this ingenious arrangement the light may be made practically continuous.

Mr. Müller's incandescent lamp is shown partly in section in two views in fig. 4. In this lamp the inventor secures the following important results: first, replacing the carbon filament without breaking or rendering useless any part of the lamp; second, preventing the entrance of air through the joints between the plug and the conductors passing through it to the carbon filament.

The glass globe or bulb is provided with a flaring strengthened neck fitting very tightly on a bevelled glass stopper or plug, which is secured air-tight by means of packing material in a hollow base, D, adapted to be screwed on or otherwise attached to a bracket or chandelier arm. The glass plug and the neck of the globe are ground together, so as to fit air-tight against each other. A packing is placed around the plug and the edge of the neck as shown. Two carbon conductors of suitable thickness are passed through longitudinal openings in the glass plug projecting from the top and bottom of the plug, and secured in the plug by a suitable cement forming air-proof joints.

Copper rings are cast or blown into the top and bottom of the plug around the apertures through which the carbon conductors pass, and these rings project slightly from the ends of the plug. Copper is then precipitated by means of electricity around the projecting ends of the carbons and the rings. By this means the projecting ends of the carbons will be strengthened and prevented from being broken off, and the joint will be made air-tight.

The upper ends of the carbons are provided with slots into which the ends of a carbon filament are passed and secured by means of a peculiar cement. A glass seal tube

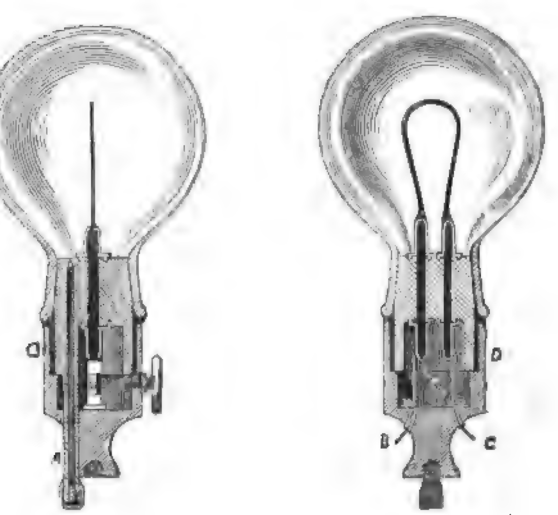

FIG. 4.

projects from the bottom of the plug through the base of the lamp, in which it is secured air-tight by means of cement. The end of this tube extends through the plug, and is contracted at its upper end. This tube is stopped at both ends, and the intervening space is filled with mercury.

Two insulated spring-contact strips project upward from the bottom of the recess in the lamp base, and rest against the lower projecting ends of the carbons. These strips are connected with conducting wires, B C, leading to the electric generator. A key journaled in the lamp base has at its inner end a crosspiece, which is of sufficient length to separate the strips and remove them from the ends of the carbons when it is in a horizontal position. When this crosspiece is in a vertical position the strips are released and rest against the ends of the carbons.

Should the carbon filament be destroyed or broken the globe is removed, a new filament is inserted, the globe is replaced, and the air is exhausted.

In addition to these interesting inventions, Mr. Müller has devised a very successful magnetic ore separator, and he has also perfected a storage battery for which great advantages are claimed.

LECTURES ON ELECTRIC LIGHT AND MOTIVE POWER.—Our readers probably noticed in the advertisement columns of our last issue that Mr. John C. Fell purposed delivering a course of eight elementary lectures on the above topic. These lectures commenced last Tuesday evening, and were continued on the following Thursday. The same course will be pursued during the next three weeks, the lectures being delivered in the Hall of the Society of Engineers, 6, Westminster Chambers. A syllabus of the course may be obtained of Fell and Wilding, 23, Rood Lane, E.C. Mr. Fell is well known to us as a science teacher, and his lectures are particularly well and clearly delivered. His long experience at the Birkbeck, and other literary and scientific institutions should enable him to give very concise and definite illustrations connected with his subject, and we can therefore safely assume that his young hearers will be materially benefited by what Mr. Fell has to say.

MEASURING INSTRUMENTS USED IN ELECTRIC LIGHTING AND TRANSMISSION OF POWER.

By Professors W. E. Ayrton, F.R.S., and John Perry, M.E.

[Read before the Society of Telegraph Engineers and of Electricians in May, 1882.]

During the last two years an enormous impetus has been given to the development of the electric light and electric transmission of power; and as accurate measurements form the basis of commercial success in this as in any other branch of engineering, we hope you may not find it too tedious listening to a short description of the details of certain instruments that we have devised and have had constructed for making accurately, and at the same time quickly, the measurements that are necessary to be made, in order that an estimate may be formed of the commercial success of any special system of electric lighting or transmission of power.

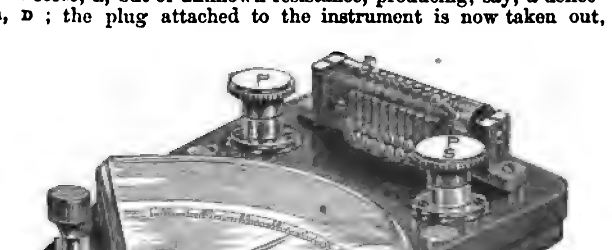
After the most charming paper given us at our last meeting, by Mr. Stroh, and of which the recollection must for a long time remain in all our minds, we feel that some apology is due to you for the rather prosy production which to-night follows it.

The chief objection to instruments used in measuring strong currents is that, first, the deflections are not proportional to the current, and, secondly, there is no easy method of calibrating the instrument—that is, ascertaining the strength of the current that is necessary to produce any given deflection. At the end of 1880, we tried in our "illuminator," used in connection with our apparatus for seeing by electricity, a method that has since been described by MM. Deprez and Carpentier, for making the deflection proportional to the current. This consisted in placing the axis of the coil, not, as is usual in galvanometers, at right angles to the axis of the permanent magnetic field, but at an acute angle with it, so that, instead of, as is usually the case in ordinary galvanometers, the magnetic moment due to the current diminishing as the needle is deflected, while that due to the permanent controlling field increases, and in consequence of which the current must increase much more rapidly than the deflection, our plan of sloping the coil causes the magnetic moment due to the currents to increase up to a certain point. But in our later instruments, indeed in all instruments with permanent magnetic fields that we have made since the commencement of 1881, we have abandoned this method in favour of giving to the coil, needle, and pole-pieces exactly the shape that theory shows to be necessary to obtain deflections exactly proportional to the current.

1. *Commutator Ammeter.*

Last year we had the honour of bringing before the society an instrument by means of which strong electric light currents can be measured, and yet which can be calibrated by the employment of a single Daniell's cell. This instrument, which we have since called an "ammeter," short for ampère-meter, contains, as the members will remember, a coil consisting of 10 strands, each of exactly the same resistance. These 10 strands, by means of a simple commutator, can be joined either in series or in parallel circuit, and so the sensibility of the instrument can be increased exactly 10 times without altering the dead-beat character of the instrument, which latter is produced by the extreme lightness of the needle and corrugated aluminium pointer and by the great strength of the magnetic field.

To calibrate the ammeter, the commutator is turned to series, and a current sent through the instrument by a cell of known electromotive force, E, but of unknown resistance, producing, say, a deflection, D; the plug attached to the instrument is now taken out,



Commutator Ammeter and Voltmeter.

which has the effect of adding a resistance of one ohm to the circuit, and a second deflection D_2 obtained. From this it can easily be shown that a current of 10 $\frac{D_1 - D_2}{D_1 \ D_2}$ E ampères will produce 10° deflection when the commutator is in series, or 1° deflection when the commutator is to parallel.

Many of the instruments are adjusted to give one ampère per degree when the commutator is to parallel; others, again, are arranged to give two ampères per degree; while some go as high as five ampères per degree, and therefore measure currents of over 200 ampères.

In designing this commutator ammeter, we originally only thought of using the high grade of sensibility for the purpose of calibrating the instrument, but we have found it extremely convenient when testing the comparatively small currents of 0·5 to two ampères used with incandescent lamps.

2. *Commutator Voltmeter.*

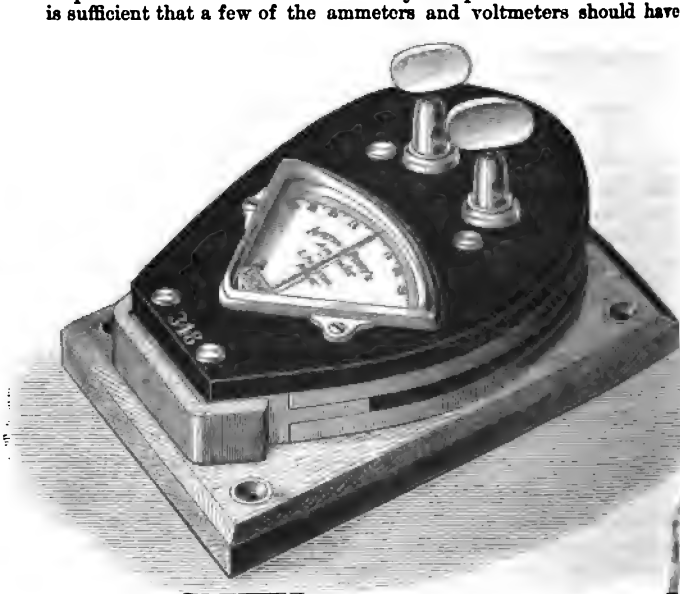
Since the reading of that paper, we have constructed a commutator voltmeter on much the same principle, but in this case each coil has a resistance of 40 ohms, so that when in series the instrument has 400 ohms resistance, and when parallel only four ohms, whereas in the ammeter the resistance in series is about 0·3 ohms and parallel 0·005, the latter being more than one-hundredth of the former, in consequence of the resistance of the small leading wires inside the instruments.* The ammeter is calibrated in series and generally used in parallel circuit, whereas the voltmeter is calibrated in parallel circuit and used generally in series, and indicates from one volt per degree in some instruments to five volts per degree in others, the total deflection of 45° in the latter case corresponding with 225 volts. But just as the ammeter can be conveniently used in series, when testing the comparatively small currents passing through a single incandescent lamp, so the voltmeter may be used in parallel circuit for testing electromotive forces of two or three volts, such as, for example, the electromotive forces of one or two Faure's accumulators. To calibrate the voltmeter, the commutator is turned to *parallel*, and a current sent through the instrument by a cell of known electromotive force, E, but of unknown resistance, producing, say, a deflection of D_1; the plug attached to the instrument is now taken out, which has the effect of adding a resistance of four ohms, and a second deflection, D_2, obtained. From this it can easily be proved that an electromotive force 10 $\frac{D_1 - D_2}{D_1 \ D_2}$ E volts between he terminals of the instrument will produce a deflection of 10° when the commutator is to parallel, or 1° when to series.

In the ammeter the resistance coil can be introduced in the circuit *only* when the commutator is to series, and in the voltmeter *only* when to parallel, so that in neither case can it be fused by the plug being accidentally taken or left out when a strong current, or, in the second case, a large electromotive force, is being measured. And more than this, to avoid the coils of the instrument itself being fused, or the needle being damaged by the instruments being arranged for maximum sensibility when currents or electromotive forces suitable for the 1-10th sensibility of the instrument are being measured, each instrument is provided with three binding screws marked respectively S (P S), and P, as seen in the figure. In all the newer ammeters the screw, P, is suitable for a thick wire, and S only for a thin, (P S) being suitable for either. Hence the wires from a dynamo, for example, can only be attached to (P S) and P, and not possibly to S. Now a current can only pass through the instrument from (P S) to (P) when the commutator is to parallel. Hence, if accidentally left to series, the circuit is merely interrupted, instead of the coils being fused or the pointer damaged by too large a deflection. Precautions of a similar kind are also taken in the construction of the voltmeter, by the use of three distinct binding screws on the instrument.

All the instruments are so wound that, when a current is sent from binding screw to binding screw, at each side of the commutator, the pointer points to that binding screw at which the positive current enters.

3. *Non-Commutator Ammeter and Voltmeter.*

In electric light factories or other places where many ammeters or voltmeters are employed, it is of course unnecessary that all should be provided with commutators for easy independent calibration. It is sufficient that a few of the ammeters and voltmeters should have



Non-Commutator Ammeter and Voltmeter.

commutators for independent calibration, the remainder, which in that case are made as shown in the following figure, being calibrated by direct comparison with the commutator ones.

In all our instruments the needle and pointer are pivoted [illegible]

* The voltmeters are now made with each coil having a resistance o[illegible] so that the instrument in series has a resistance of 2,000 ohms, an[illegible] circuit, 20 ohms, the resistance coil being also of 20 ohms.

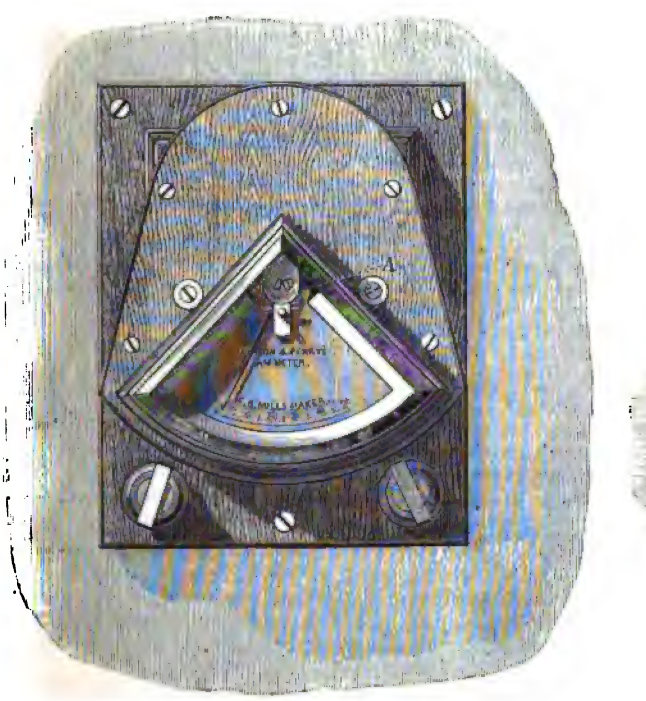
axis passing through their common centre of gravity, so that the deflexion is unaltered, no matter in what position the instrument be held, and the pivot resting in jewels top and bottom, the friction is also practically unaltered by turning the instrument on its side or holding it upright. The permanent attached magnet is also so strong, that the ammeters or voltmeters may be placed not very far from even a dynamo machine in action, without the magnetism of the machine affecting the indication of the instruments.

One difficulty, however, has practically arisen in the use of these instruments, and that is, although the special mode of winding adopted, combined with the existence of the commutator, enables any one by means of a single good Daniell's cell to calibrate his instrument for himself, practically Daniell cells do not exist at many places where there are electric light installations, and consequently people do not calibrate their instruments for themselves, and so do not detect the changes of magnetism in the permanent magnets which necessarily occur, and against which the user is warned by a notice stuck in the lid of the box accompanying every ammeter or voltmeter.

To partially avoid the loss of magnetism in the controlling permanent magnets, an armature, seen in the last figure, is supplied with each instrument, but which of course must be removed when the instrument is in use.

4. *Spring Ammeter and Voltmeter.*

To however completely overcome this difficulty of loss of magnetism in the permanent magnets, we have decided to abandon permanent controlling magnets, and so we have constructed ammeters and voltmeters like those shown in the following figure, and in which the controlling force is that of either a flat or a cylindrical spiral spring, A, the axis of the soft iron needle in this case making an angle less than a right angle with the axis of the coil when no current is



Spring Ammeter and Voltmeter.

passing, since if it made a right angle it would be in unstable equilibrium when a current passed. The best angle that the axis of the needle should make with the axis of the coil when the pointer points to nought, we have determined partly by calculation and partly by a long course of experiments, and we find that, with a proper initial adjustment, we can obtain deflections of the pointer up to 45° *directly proportional* to the current.

These instruments possess two important advantages not possessed by any of our earlier forms—the one being that they can be used with reverse currents; the second, that by giving any special set to the spring (for doing which there is a small hand, seen in the figure, and which can be turned through any angle indicated by a small graduated scale, A, under it), the needle does not start from the zero position until the current in the ammeter or electromotive force in the voltmeter exceeds a certain pre-arranged limit. This method of giving a set to the spring greatly increases the sensibility of the instrument. Suppose, for example, currents of about 30 ampères, or currents varying, say, from 25 to 35 ampères, are to be measured with a special instrument, then instead of the pointer starting from nought for even a small current, a set is given to the spring, so that the pointer does not leave the zero until a current of 25 ampères traverses the coils. In the former case, the spring would have to be so strong that the total possible deflection, 45 degrees, was produced by the 35 ampères—that is about 1·3° per ampère; whereas, in the latter case, a weaker spring set-up would be used, such as to be deflected through the 45° for an addition of 10 ampères to the 25 necessary to start the pointer. In the latter case, we should have 4° per ampère, or a sensibility about three times as great as before.

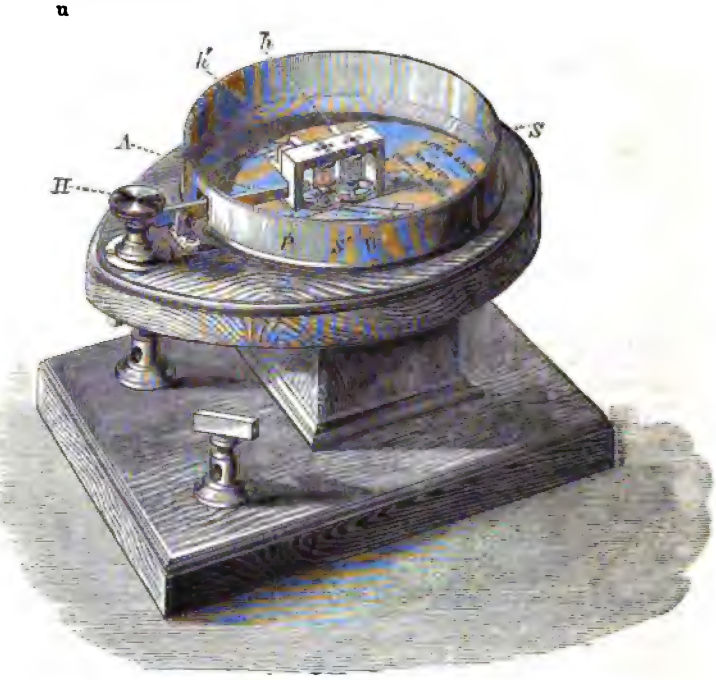
Spring voltmeters on a similar principle we have also had made.

5. *Wheel and Pinion Ammeter and Voltmeter.*

Where still greater delicacy is required, the form of the instrument is somewhat changed. Attached to the arbor of the needle is a wheel, W, with extremely finely-cut teeth gearing into those of a pinion, P, on the arbor to which the pointer is attached. With this arrangement the motion of the pointer is magnified ten times. If, then, the coil and needle have such a shape, and the axis of the needle makes such a proper initial angle with the axis of the coil that the deflection of the needle up to not more than even 36° is proportional to the current, then with our wheel and pinion arrangement the deflection of the pointer over the entire scale of 360° will be proportional to the current. In addition to these, both the arbor of the needle as well as the arbor of the pinion are provided with very delicate cylindrical spiral springs, S, S', one or both of which may be employed, since the latter can be thrown out of gear by raising the arm, A, which is done by turning the head; H, of the adjusting screw. If both the springs be of the same strength, then the sensibility of the instrument can be instantly made exactly one hundred times as great by turning the milled head, H, which raises the arm, A, and throws S' out of gear, or can be increased to any other known less or greater pre-arranged amount, by having the spring on the pinion weaker or stronger than that on the wheel.

Both springs have, further, little hands, *h*, *h'* (seen in the figure), for setting them up, so that the whole deflection of 360° may, if desired, be produced by a small percentage of change in the total current when it is wished to measure accurately small changes in a fairly constant current. The wheel and pinion ammeter, then, furnishes an instrument for the measurement of strong currents, comparable in delicacy with the instruments usually employed for the measurement of only weak currents. Every bearing is jewelled as it is in a good watch, hence the freedom of motion is very great.

An ammeter on this principle we are now constructing, to measure p to 1,200 ampères.
u



Wheel and Pinion Ammeter and Voltmeter.

On a similar principle, we have constructed wheel and pinion voltmeters, with two grades of sensibility, for measuring electromotive forces with great accuracy.

By means of simultaneous measurements of the currents flowing through a circuit, and the difference of potentials between its two ends, the horse-power electrically given to that circuit can be ascertained, since this horse-power equals A × V × ·00134, where A is the current in ampères and V the difference of potentials in volts; also A × V × 44·25 equals the number of foot-pounds of work per minute electrically given to that part of the circuit.

6. *Bifilar Suspension Electric Power Meter.*

In the paper read by us last spring at the Society of Arts, we described an electric power meter which we had arranged for measuring by one observation the horse-power electrically given to any part of the circuit, and which, by the employment of our commutator principle, could be calibrated by employing very much smaller powers than the instrument was intended to usually measure. At the York meeting of the British Association, we exibited the instrument which we had been employing for this purpose, consisting of a coil of very fine wire wound on a long thin bobbin, so that the coil had a very small moment of inertia, capable of moving about an axis parallel to the length of the bobbin. The coil was bifilarly suspended inside another fixed coil containing 10 thick wires, each of exactly the same resistance, and which, by means of the commutator, could all be joined up in series or in parallel.

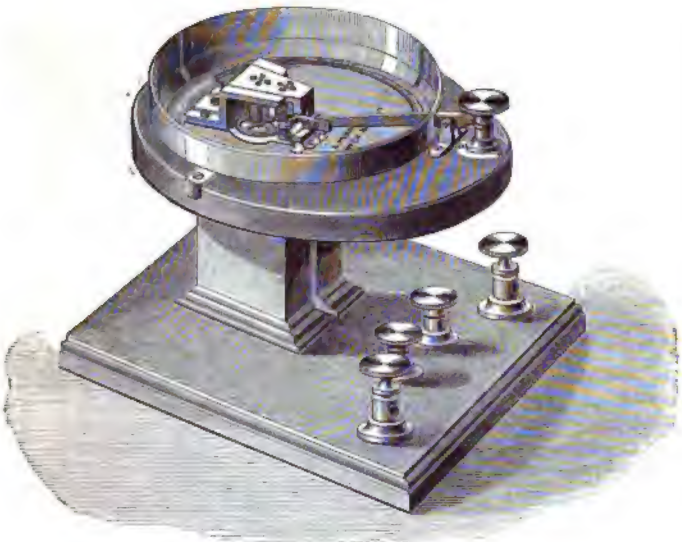
The thick wire coil is placed in the main circuit, while the fine wire coil acts as shunt to that part of the circuit, P, Q, the horse-power electrically given to which it is desired to measure. The current passing through this fine wire coil therefore measures V, the difference of potentials between P and Q, hence the deflection of the coil measures the product of the main current, A and V, and consequently

the horse-power being electrically given to P, Q. By turning the commutator to series, the sensibility of the instrument can be increased exactly ten times, either for the purpose of calibration, or when it is required to measure the power being given to, say, one incandescent light.

At the same meeting of the British Association, Sir William Thomson, before seeing our electric power meter, described an instrument he proposed constructing on the same principle, and which he called an electro-ergometer. We have not employed this name, because it appears to us to be not quite apt, since such an instrument measures the rate of doing work which is power, and not the *ergs* or amount of work done.

7. *Wheel and Pinion Electric Power Meter.*

This year we have modified our electric power meter, employing the wheel and pinion and double spring already described in connection with the wheel and pinion ammeter and voltmeter, so that this instrument now takes the shape shown in the following figure.



Wheel and Pinion Electric Power Meter.

The outer and larger binding screws are for taking the wires which form part of the main circuit; the inner smaller binding screws for the finer shunt wires which are attached to that part of the circuit, the energy electrically expended in which it is desired to measure. One or both springs can be employed, and so two very different grades of sensibility are possible; also a definite amount of angular set can be given to either, so that a small change in a large horse-power will cause a great change in the deflection of the pointer.

8. *Transmission Dynamometer and Dynamometer Coupling.*

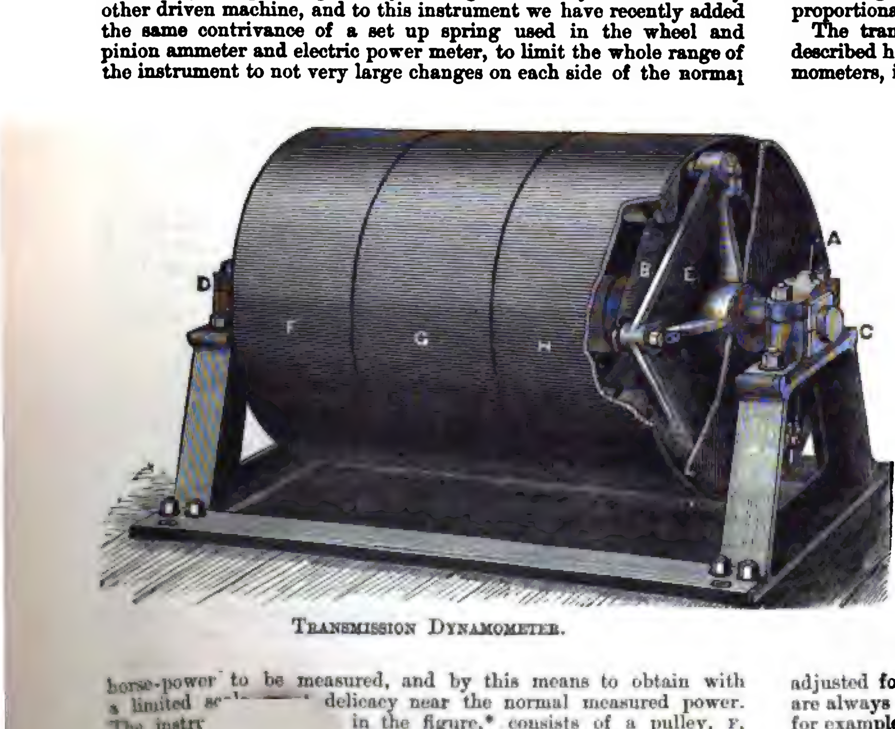
When describing our original ammeter to this society, we described a form of transmission dynamometer we had devised for measuring the power given by an engine to a dynamo or to any other driven machine, and to this instrument we have recently added the same contrivance of a set up spring used in the wheel and pinion ammeter and electric power meter, to limit the whole range of the instrument to not very large changes on each side of the normal horse-power to be measured, and by this means to obtain with a limited sc[illegible] delicacy near the normal measured power. The instr[illegible] in the figure,* consists of a pulley, F, rigidly fi[illegible]t, C D, a loose pulley, G, and a pulley, H, joined by the spiral springs, B, to the ribbed plate, E, which is rigidly fixed to the shaft, C D. If, then, the engine belt is on F, and the belt to the dynamo or driven machine on E, or *vice versâ*, the springs, B, will be stretched, depending on the "torque" or twist transmitted. The extension of these springs causes, by means of a small link-motion seen at the lower right hand curve of the figure, the bright bead, A, at the end of a long arm to approach the centre. Hence the smaller the radius of the circle described by this bright bead as it revolves, the greater the torque. Consequently, the horse-power transmited is at once obtained from observing the indicated torque and the speed of rotation. The arm carrying the bead is slightly flexible, and when no power is being transmitted the bead is pressed with a certain force against the rim of the front plate, hence the bead does not commence moving until a certain pre-arranged horse-power at a given speed is being transmitted; its whole radial motion, therefore, is completed for a certain additional transmitted horse-power, the necessary addition depending on the power of the springs and the leverage of the link motion. Consequently, a large change in the radius of the circle of light is produced by a small change in the transmitted horse-power. Further, one of the pins in the links can be taken out and put into another hole, which has the effect of greatly altering the leverage of the links, thus increasing the magnification and causing the motion of the bead to be completed for another range of power. For example, the springs and link motion may be so arranged that with one of the two adjustments the bead may commence to move when eight horse-power is being transmitted at a certain speed; the whole motion from the circumference to the centre may be completed, when the horse-power transmitted varies from eight to 12. With the other adjustment, the bead may start moving when four horse-power is being transmitted, and the entire travel of the bead from the circumference to centre completed by this transmitted horse-power increasing from four to six. Slipping either the driving or the driven belt on to the loose pulley, G, causes the transmission dynamometer and the dynamo machine to stop while the engine is going on.

The next figure shows our dynamometer coupling, which differs only from the preceding in that it is intended to be used with machinery driven directly by shafting where belting is not employed. For instance, this coupling may be used to measure the horse-power given by a fast-speed engine to a dynamo driven directly by it, or it may be employed to measure the power given by a marine engine to the screw or to the paddles, or generally the horse-power transmitted along any line of shafting; the spring coupling, in fact, replacing the ordinary coupling used with such shafts.

One of the halves of the coupling seen in the figure is keyed to the driving shaft—for example, the shaft of a fast-speed engine—and the other to the driven shaft—for example, that of the dynamo. The half, C, is attached to the other half by means of the spiral springs, and the stretching of these is therefore a measure of the torque. The angular motion of the one relatively to the other causes the bright bead, B, to approach the centre, and, as before, the radius of the circle of light measures the horse-power transmitted at any particular speed. The arm, E, carrying the bead, is also, as before, slightly flexible, so that when no power is being transmitted the bead, B, is pressed with a certain force against the rim of the larger plate. Hence the bead does not commence to move until a certain pre-arranged horse-power, at a given speed, is being transmitted, and the whole motion is completed for any pre-arranged excess beyond this, thus enabling delicate measurements to be made at powers a little more or less than that normally transmitted.

By a proper arrangement of the link-motions, we have succeeded in making the radial motion of the bead in both instruments exactly proportional to the extension of the springs or twist transmitted.

The transmission dynamometer and dynamometer coupling just described have the great advantage over any sort of laboratory dynamometers, in that the former have not to be put into position and adjusted for each particular experiment, but are always ready and are always indicating the power transmitted at any given speed. If, for example, a dynamometer coupling be inserted in the shafting of a factory in place of the ordinary coupling, a glance at it at any time will show the power that is being transmitted by it. If two such dynamometer couplings be inserted at two places in the same set of shafting, the difference between the transmitted powers indicated by



Transmission Dynamometer.

Dynamometer Coupling.

* The [illegible]ure are from blocks used in Professor Perry's book on "P[illegible]out to be issued by Messrs. Cassell, Petter, and Galpi[illegible]ed us the use in advance of these two illustrations.

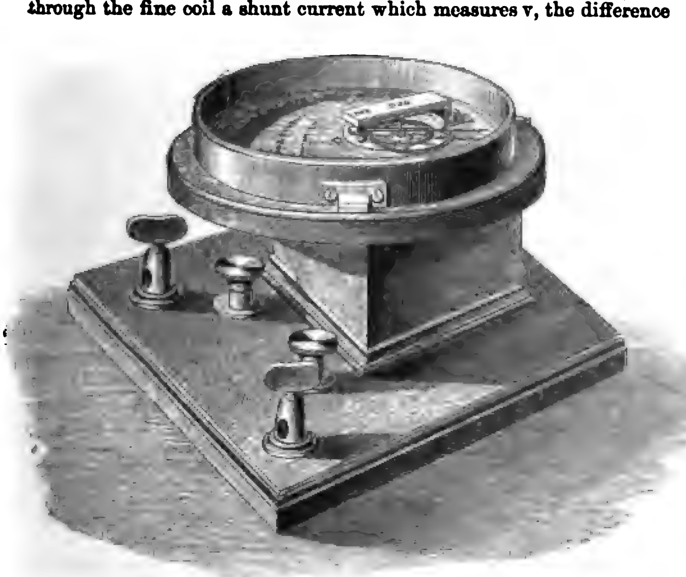
them is the power utilised by the machinery driven by that portion of the shafting that is between them. At present, masters of works, we think, have necessarily but rather a vague idea of the amount of power expended in different parts of their works—how much, for example, is used to drive one portion of the machinery and how much to drive some other The substitution of a few dynamometer couplings, at well-chosen places, for the ordinary couplings, would settle this question.

9. *Ohmmeter.*

The next instrument, which, like all the preceding electric ones, is constructed by Messrs. Paterson, of 76, Little Britain, is for the purpose of measuring the resistance of any part of, say, an electric light circuit, while the strong current is flowing. At present the resistances of the field magnets, the bobbins of electric lamps, &c., are measured with the Wheatstone's bridge when cold, and a guess is made at their resistance when hot by making a rough estimate of the temperature. A better plan than this is to stop the current, and quickly measure the resistance before the circuit has had time to cool; but even this method of measurement can only lead to approximate results, and is of course quite inapplicable to the resistance of either an arc or an incandescent light. In such cases it is usual to measure the main current in ampères with an ammeter, and the difference of potential in volts with a voltmeter, between the two terminals of the lamp, since dividing the second reading, V, by the first, A, we have the ratio $\frac{V}{A}$ or R, the required resistance. And this method we have been in the habit of employing, not merely to measure the resistance of a lamp, but the resistance possessed by any part of the circuit while the current was flowing through it.

To avoid, however, always having to take two measurements, we devised some months ago an instrument which we have at length perfected, for measuring the ratio at one reading, and this instrument, called an "ohmmeter," differs from the power meter in that, while the latter measures the product, V A, the ohmmeter measures the ratio, $\frac{V}{A}$.

This instrument consists of two coils, one of thick and the other of fine wire. Both coils are fixed, and with their axes at right angles to one another, and the currents flowing through each act on the same needle. Through the thick coil the whole current, A, flows, and through the fine coil a shunt current which measures V, the difference



Ohmmeter.

of potentials between the two ends of the part of the circuit the resistance of which it is required to measure; and the forces due to these two currents are at right angles to one another, hence the deflection of the needle may be made to measure $\frac{V}{A}$. By giving the proper mathematical shape to both the coils and to the needle, we have succeeded in obtaining the instrument seen in the accompanying figure, in which the deflections from zero are directly proportional to the values of $\frac{V}{A}$, that is, to the values of the resistances to be measured.

When the instrument is not in use, there is no directing force acting on the needle, and the pointer therefore remains anywhere. On allowing the main current to pass through the thick coil, by means of the outer and larger binding screws, the axis of the needle instantly places itself along the axis of the thick coil, and the pointer points to nought. If now wires be attached to each of the small binding screws belonging to the fine coil, and the other ends of these two wires be attached to the *same* point of the main circuit, the pointer still remains at nought, indicating that there is no resistance in the main circuit between the two points of attachment of the fine wires. If these wires be separated by, say, the field magnets of the dynamo, the pointer at once moves to a number indicating the resistance of the field magnets, &c. It will be seen, then, that the resistance of any part of the circuit can be measured at any time without interfering with the main current.

In actual practice, in fact, the ohmmeter is simply kept inserted in the main circuit anywhere, and when it is desired to measure the resistance of any part of the circuit, all that is necessary to be done is to connect, by means of two fine wires, the two ends of this part of the circuit to the two smaller binding screws of the ohmmeter.

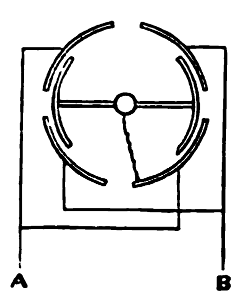
By the employment of the wheel and pinion, a deflection of about 320° of the pointer is obtainable, and on the present instrument a deflection of 60° corresponds with one ohm, so that measurement of resistances up to six ohms correct to 1-60th of an ohm can be accurately and quickly made. By altering the resistances of the two bobbins, the measured resistance corresponding with any particular deflection can be made anything we please.

One great use of the ohmmeter is that it enables us to dispense with resistance coils for experiments on dynamo machines. Any one who has used the resistance coils made for such purposes knows the difficulty of making coils of convenient size, whose resistances do not seriously alter with currents of 30 or 40 ampères. The coils cannot easily be made to cool fast enough to avoid the resistance seriously increasing with the current. We, on the other hand, use a bit of carbon, a bit of wet rope, or a pail of water, and measure with the ohmmeter the resistance of our extemporised resistance coil at the moment of making any experiment.

10. *Cylinder-spring Electrometer.*

For measuring differences of potential higher than 500 volts, the voltmeters already described are unsuitable, and recourse must be had to a portable modification of some form of Thomson's electrometer. We have devised two or three forms, one of which is seen on the table.

Two vertical pieces of metal, forming part of a cylindrical surface, are attached to a vertical arbor resting in jewelled bearings, and form the needle of the electrometer. This arbor is fixed to one end of an extremely fine spiral spring, the other end of which is fastened to the dial plate, which is itself electrically connected with one of the terminals, A. This spring serves two purposes—the one to give the needle directive force, the other for keeping up electric connection with the needle which turns inside four concentric vertical pieces of brass, which together nearly form a complete cylinder of a radius slightly larger than that of the needle, and which replaces the quadrant in the ordinary electrometer. These are electrically connected alternately in pairs, as shown in the small figure; and one pair is also connected with the needle through the very fine cylindrical spring, symbolically represented as a spiral line in the small figure. If, now, A and B be maintained at a difference of potential, E, a deflection, D, will be produced, which it may easily be shown is proportional to the square of E. One great advantage of this well-known method of connecting up the needle and quadrants of a Thomson's electrometer is, that although it does not produce as delicate an instrument as can be obtained by giving to the needle an independent charge, it enables the instrument to be used for measuring a rapidly-reversing electromotive force equally well as for



measuring a non-reversing electromotive force; whereas a fine wire galvanometer or dynamometer cannot be satisfactorily used for measuring even a small rapidly-reversing electromotive force, on account of the retardation arising from self-induction.

The advantage of the special modification above described of the quadrant electrometer is that it is portable; and from the needle having but a small moment of inertia, while at the same time it is everywhere very near the fixed attracting surfaces, the instrument may be made partly dead-beat, and at the same time sufficiently delicate to measure the large electromotive forces for which it has been designed.

If it is desired to measure the horse-power electrically expended in any portion, P Q, of a circuit conveying an alternate current, a measurement of the strength of the current may be made with a suitable ammeter, and a simultaneous measurement of the difference of potentials between P and Q with an electrometer. The following arrangement of the electrometer, however, enables the mean product of the alternate current and alternate difference of potentials between P and Q to be measured with the one instrument:—

Let it be desired to measure the energy electrically expended in a portion of the main circuit between two points, A and B, whose potentials are P and Q respectively. Connect these two points to the opposite fixed cylinders in the previous electrometer. Place in the main circuit, on either side of the portion, A B (say, on the A side), a resistance, R, having no self-induction, and let its farther end, C, of which the potential is S, be connected with the movable cylinder of the electrometer; then the deflection, D, measures the mean value of $(P - Q)\left(S - \frac{P + Q}{2}\right)$. Now connect the needle with A, instead of with C; then the deflection, D, measures the mean value of $(P - Q)^2$. Hence $D - D'$ measures the mean value of $(P - Q)(S - P)$, which is obviously R times the mean value of the energy expended on the portion of the circuit, A B.

A variation may be made in the second test, and which consists in

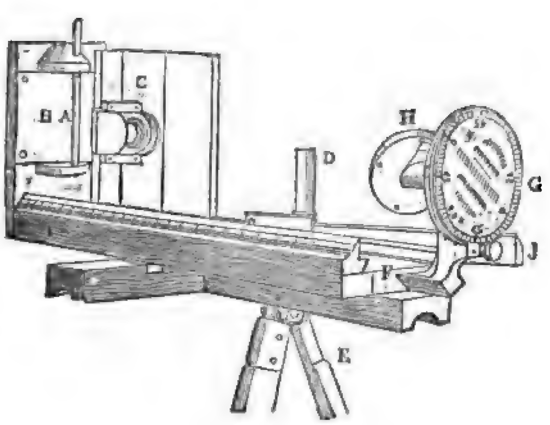
connecting the needle with a point, D, in the resistance coil, such that the resistance between D and A is $\frac{R}{2}$; in that case D″ will measure the mean value of $(P - Q)\left(\frac{S+P}{2} - \frac{P+Q}{2}\right)$, in which case D — D″ measures the mean value of $\left(\frac{(P - Q)\,(S - P)}{2}\right)$, or $\frac{R}{2}$ times the mean value of the energy expended.

12. *Dispersion Photometer.*

With this photometer measurements may be made in quite a small room of the illuminating power of the rays coming at any angle from even a powerful electric light. With the ordinary forms of photometer, the screen illuminated by the electric lamp must be placed so far away from the lamp that its brightness is the same as that of another screen, or of the other side of the same screen, illuminated by the standard candle. With the powerful electric lamps of the present day, a distance of 50 or 100 ft. is necessary, in order that a measurement may be made of the illuminating power by means of an ordinary photometer, and, in addition, it is very difficult to examine the light unless it comes from the lamp in a horizontal direction.

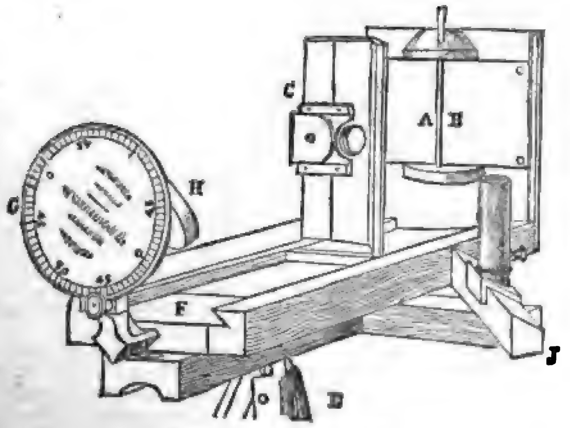
The principle of our dispersion photometer consists in the use of a concave lens to weaken the strength of the light (instead of placing the lamp far away from the screen), combined with the employment of a mirror turning round a horizontal axis, which makes an angle of 45° with its reflecting surface, in consequence of which rays coming at any angle from the lamp can be measured without the introduction of an error arising from the varying absorption at different angles of reflection; while at the same time a pointer attached to the mirror reads off on a graduated scale, G, attached to the instrument, the angle made with the horizontal by the beam of light under examination.

The instrument seen in the figures consists of a portable tripod stand, E, on which is screwed a small table, which is then carefully levelled.



DISPERSION PHOTOMETER.

The photometer is next placed on this table, and the pin at F, directly under the centre of the mirror, is passed through the base of the photometer into the hole in the table. The photometer, by turning round this pin, can, without producing any change in the distance of the centre of the mirror from the lamp, and therefore without changing the distance from the screen to the lamp, receive the small horizontal motion necessary for the adjustment for a new



DISPERSION PHOTOMETER.

inclination of the rays coming from the electric light. The divided circle, G, is clamped with the index at 0°, the electric lamp is lowered or raised till the illuminated disc formed on the screen of blotting paper, B, by the reflected light, passing afterwards through the lens, is [illegible] of the paper screen. A little sliding shutter with [illegible] its centre, seen in the figure, enables a very exact [illegible] made; but in practice we find that we get suffic[illegible] the use of the shutter. The instrument having b[illegible] the distance from the electric lamp to the centre o[illegible] measured.

The candle in the holder, D, sliding on the graduated rod, J, having now been lighted, there will be seen cast on the screen of blotting-paper, B, two shadows, side by side of the black rod, A, placed in front of it, one being cast by the standard candle, the other by the beam from the electric light after reflection at the plane silvered mirror, H, and dispersed in passing through the concave lens in the sliding wooden frame, C. The lens is now moved backwards and forwards until the intensities of these two shadows are equal when seen through the sheet of red glass supplied with the instrument, and again adjusted until the shadows are of the same intensity when seen through the sheet of green glass. *d*, the axial distance of the lens from the screen, as shown by the pointer attached to the lens frame on the fixed graduated scale, as well as *c*, the distance of the candle, also shown by position of its pointer on its graduated scale, are now noted; whence if *f* is the focal length of the lens, and if D is the distance of the lamp from the paper screen (that is, the distance of the lamp from the mirror, plus the fixed distance of the mirror from the screen), and if L is the strength of the examined source of light in standard candles,

$$\sqrt{L} = \frac{D - d}{c} \cdot \left\{ 1 + d\left(\frac{1}{f} + \frac{1}{D - d}\right)\right\},$$

or

$$L = \frac{1}{c^2}\left\{ D + \frac{d(D - d)}{f} \right\}^2.$$

We prefer to employ the formula; but as all the common instruments which have hitherto been manufactured have lenses whose focal length is four inches, we have prepared a table, a copy of which is sent out along with each instrument, in which the value of L is given for various values of D, *d*, and *c*. Using this table, it is necessary to have the lamp at either 60, 120, or 300 inches from the screen; the candle is either at 10, 14·14, or 20 inches from the screen; and the table is made out for every half-inch of the lens-scale. But inasmuch as we find that the improved arrangement of the mirror already referred to constitutes perhaps the most useful part of the instrument, and as the use of this improvement involves many alterations of D, Mr. Sennett, of the Kirby Street Engineering Works, Hatton Garden, the manufacturer, proposes in future not to furnish any table of the values of L unless specially asked for.

In these instruments we find that from 30 to 34 per cent. of the incident light at 45° is absorbed, whether this light is of ruby-red or signal-green colour, and practically none by the lens; so that we have the easy rough practical rule for all cases—add one-half to the measured intensity of light reflected. For more accurate working the exact absorption of the mirror of the particular instrument employed is used.

The intensity of the horizontal beam having been measured, the electric lamp is now raised or lowered and fixed in any position; a few seconds suffice to turn the mirror so that it sends its centre ray exactly through the centre of the lens. The distance from screen to mirror in this instrument being 22 inches, if δ is the distance from centre of mirror to vertical from lamp, and if θ is the angle of elevation, then

$$D = 22 + \delta \sec. \theta.$$

Using this value of D in the formula above, and adding one-half to the strength of the light to make up for absorption, or making the more accurate correction for the special instrument employed, the true intensity of the light in standard candles can be ascertained. In practice, if an electric light is moderately steady, ten measurements may be made, with some confidence in their accuracy, in two minutes; and the light may be measured in ten different positions, from an angle of depression of 60° to an angle of elevation of 60°, 100 observations being taken in less than half an hour.

We may mention one very important result we have been led to by the systematic employment of a photometer which can be used close to the electric light, and that is the large amount of absorption that occurs on certain days when the rays from strong electric lights, and especially the green rays, pass through the air, which appears to the eye perfectly clear. At first we were inclined to think the higher results for the candle-power of a lamp obtained with our dispersion photometer than those obtained with an ordinary distance photometer were due to some error in our photometer itself; but we have since ascertained that this is due to the absorption of the air, because we find that, if simultaneous measurements are made with ordinary Rumford's photometers, each without lens or mirror, placed at different distances from the lamp in the same azimuth and in the same horizontal plane, the nearer one gives, as a rule, the highest readings, and the difference is the greater the stronger the light, and is greater if the light be examined at each photometer with green glass. The importance of such experiments in connection with the penetrating power of the electric light must be obvious.

13. *Electric-light Calculator.*

Having had occasion to make a large number of calculations of the illuminating power of various electric lamps, the horse-power electrically given to them, and the "efficiency" or number of candles per horse-power produced, we have devised and had constructed a simple piece of apparatus by means of which all the necessary calculations can at once be made, and which, after being used to work out the results obtained from any one experiment, preserves, until it is again used, a record of all the numbers employed in the previous calculations—an arrangement which serves as a valuable check in preventing clerical errors. The apparatus consists of four concentric discs graduated logarithmically, after the manner of the slide rule. The observed distance of the electric light from the photometer screen is sought for on scale 1: opposite this is brought the observed distance of the candle read off on scale 2, and

the pointer shows at once the candle-power of the lamp. On scale 3 is read off the current in ampères passing through the lamp, and opposite this is brought the observed difference of potentials in volts between its terminals read off on scale 4, when the second pointer shows at once the horse-power electrically given to the lamp. Finally, the illuminating power as shown by the first pointer is brought opposite the horse-power, as shown by the second, when the number of candles per horse-power is at once read off.

14. *Coulombmeter.*

We have also, mainly for the purpose of experimenting on charging and discharging Faure's accumulators, arranged an apparatus which registers the total quantity of electricity that has passed through it in any previous given time—an apparatus, in fact, which acts for electricity as a gas meter acts for gas. This coulombmeter is simply a small magneto-electromotor placed as a shunt to the main circuit, and acted on by *fluid friction*, which forms the essence of the apparatus, since such fluid friction opposes a resisting force directly proportional to the velocity, while, on the other hand, the force causing motion is proportional to the current; hence the current flowing is proportional to the velocity, and the total quantity of electricity that flows in any time is proportional to the total number of revolutions made by the motor in that time, which are counted by an ordinary speed-counter attached to the revolving spindle. Hence the number of coulombs of electricity that have passed may be measured, by taking two readings of the counter, as easily as can the number of cubic feet of gas consumed by taking two readings of the gas meter.

This coulombmeter we have used for some time; but we have found this week that an instrument somewhat of this nature was patented some time back by Mr. Edison, although we are not aware that he has ever used it, or whether he realises the absolute necessity of the existence of a fluid friction. To him, however, we must yield up the priority of invention for this form of coulombmeter.

We have a strong current available, and we will now proceed to test experimentally all these various instruments which you see in the room before you, and which have been designed and constructed in each case to supply an actual need, which our experiments led us to see existed, for exact, portable, and moderately cheap measuring instruments for use in electric lighting and electric transmission of power.

GROVES'S DISCHARGE KEY.

THE discharge keys in general use perform three operations —charge, insulate, and discharge. Mr. Robert Sabine, however, to suit his own testing arrangement, introduced an additional lever and cam by which the three contacts are brought into metallic connection, thus short-circuiting the key. The design of such keys is of a mixed character, and, although made of high insulating material, they are not provided with any protection from light, air, and dampness, consequently they somewhat rapidly deteriorate and require careful preparation before use.

The key about to be described will perform the four operations above mentioned, and is made with protection for the contacts and insulation, especially the principal (cable) terminal, and the design is of a general character. Fig. 1 represents the external appearance. A is a brass case with glass cover, D, having a hole through which passes the cable terminal, C; there is a space between the glass cover and the terminal which is closed when not in use with an ebonite disc or washer which slides upon the terminal. This said terminal passes through a hole in the base and is prolonged under the ebonite slab to the frame, thus giving six inches of insulation, and it is protected from light and air. On

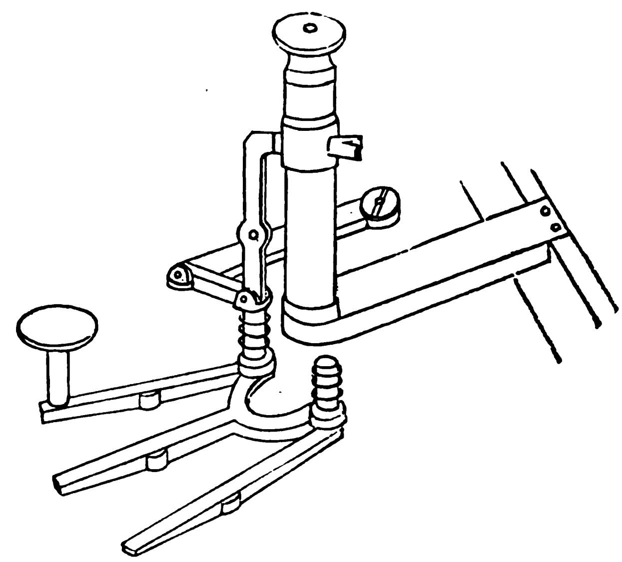


FIG. 2.

each side of the upper end of the cable terminal is fixed a V-shaped contact stud, into which the end of a crank lever is pressed, the pressure being given by a spiral spring when a lever connected with the studs is raised. The terminals, G and B, are well insulated, but they are not so important as the cable one.

Fig. 2 is a sketch of the working arrangement. One of the crank levers is left out to prevent confusion. The studs are arranged in a similar manner to those employed in Wheatstone's A B C instruments, consisting of pulleys and a chain; when one stud is depressed the one already down is raised, and only one can be pressed down at a time. The merits claimed for this key are certainty in its action and easiness of manipulation (it only necessitating the depression of one of the studs, S, to produce the result required), high insulation, and the protection of the contacts. A vessel of sulphuric acid can be placed in the case to absorb any moisture that may have got in.

The maker of this key is Mr. Groves, of 89, Bolsover Street, W., and he is doubtless well known to most of our readers as having formerly been the assistant of the late Sir Charles Wheatstone, for whom he carried out many of his most important experiments.

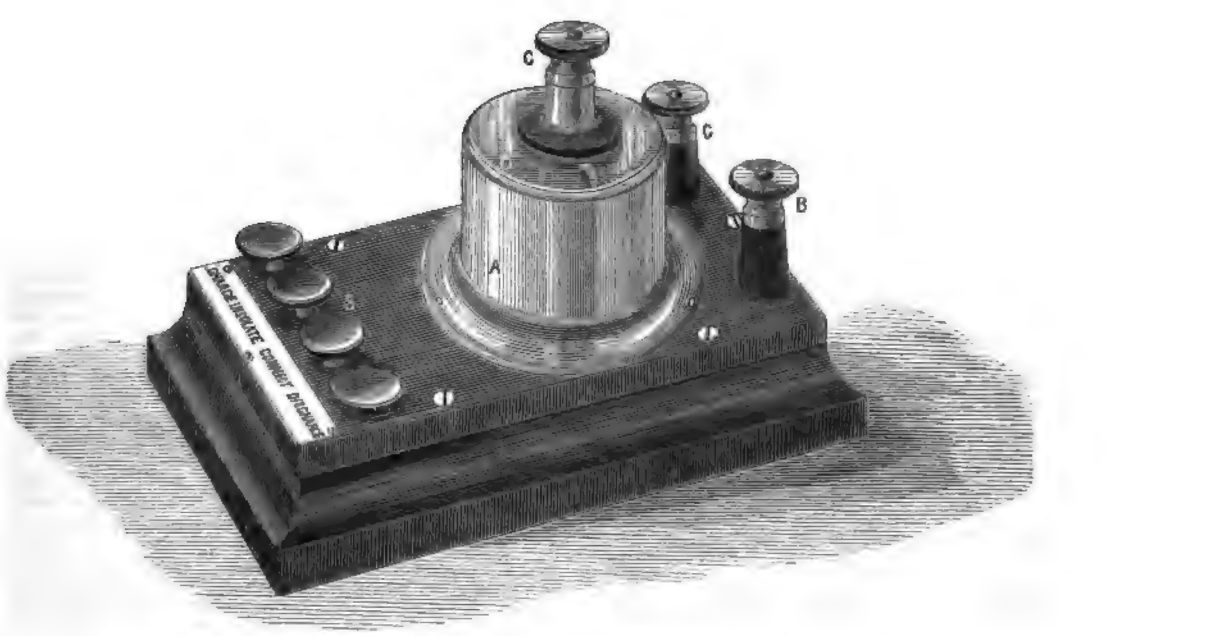

FIG. 1.

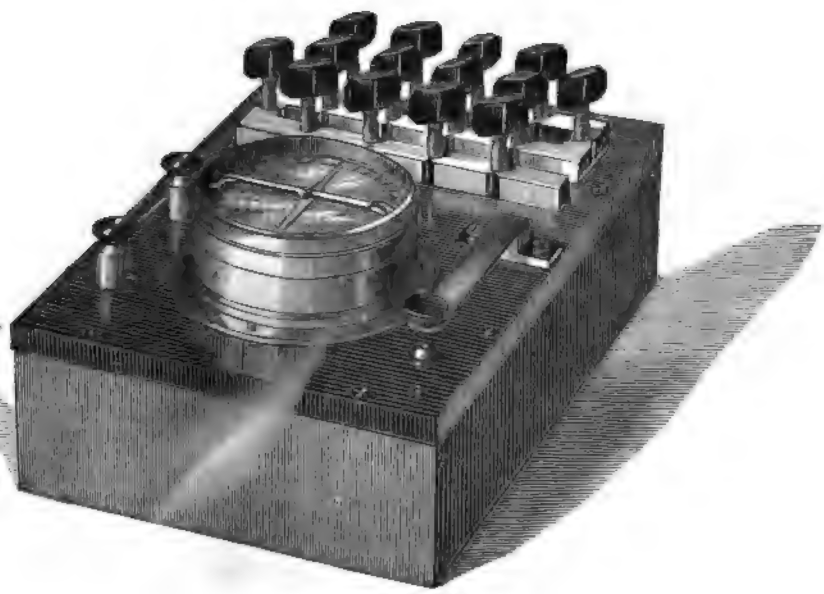
SIMMONS'S PORTABLE TESTING BOX.

WE have recently had an opportunity of examining and using one of these very useful and compact testing boxes for measuring resistances. That with which we have been operating is arranged to measure from 0·01 to 20 ohms. The resistances are made up as follows: ·01, ·02, ·02, ·05, ·1, ·1, ·2, ·5, 1, 1, 2, 5 and 10 ohms. There is also an "infinity" plug, so that the adjustable resistance may be broken.

The "Wheatstone bridge" method is not employed in this apparatus, and we need, therefore, scarcely inform our readers that the galvanometer is wound differentially. We believe that each side has a resistance of about 15 ohms. The battery consists of four small Leclanché elements of the medical type, connected up for quantity, and virtually forming one large cell. This is fixed in the interior of the box, and the various connecting wires are permanent and hidden from view. The wire or coil whose resistance is unknown is attached to the two binding screws, and the adjustable resistance unplugged, until no movement of the galvanometer needle is observed. A contact key is



arranged on the box for the purpose of putting the battery in circuit. The sensitiveness of this instrument is such that resistances can be easily measured to two places of decimals; and if greater accuracy be desired, it can be obtained, as is sometimes done with the "Wheatstone bridge" arrangement, by proportional deflections. For all practical purposes the second decimal place suffices, except in such an extreme case as measuring, for instance, the armature resistance of a large Edison dynamo-electric machine. Mr. Simmons, however, makes up the various resistances contained in his boxes for any particular requirements.

Mr. Simmons for several years took a prominent position in the business of Messrs. Elliott Brothers, and this fact alone is sufficient to guarantee excellence and accuracy of workmanship, together with an electrical knowledge of no common order. We should imagine that such an apparatus would be of great service to electric light engineers, especially to those members of the profession who are continually travelling about, installing the electric light in various towns. The veriest tyro can manipulate this instrument after its operation has once been explained, for electrical knowledge is not necessarily requisite. We can cordially recommend this testing box, and we do not doubt but that Mr. Simmons will find his compact combination se[illegible]

Th[illegible] shows all that is necessary in order to [illegible] construction of the apparatus, and it is [illegible]avelling case, 11 by 8 by 5½ inches.

THE BRITISH ASSOCIATION.

[*Specially reported for the* ELECTRICAL REVIEW.]

THE ELECTRO-MAGNETIC PRACTICAL SYSTEM OF UNITS.

[Paper read by Dr. C. W. SIEMENS, before Section A, Tuesday, 29th August, 1882.]

SINCE referring to the subject of electrical units in my presidential address, I have been requested by several members of this section to bring the matter again before you, to afford an opportunity for its fuller discussion. I have great pleasure in acceding to the request, as I am most anxious to hear the views of the members of this section on the several units which I ventured to add to the list decided on at the Paris Electrical Congress.

At this Congress, which was attended officially by the leading physicists of all civilised countries, the attempt was successfully made to bring about a union between the statical system of measurement that had been followed in Germany and some other countries, and the magnetic or dynamical system developed by the British Association, also between the geometrical measure of resistance, the (Werner) Siemens unit, that had been generally adopted abroad, and the British Association unit intended as a multiple of Weber's absolute unit, though not entirely fulfilling that condition. The Congress, while adopting the absolute system of the British Association, referred the final determination of the unit measure of resistance to an International Committee, to be appointed by the representatives of the several Governments; they decided to retain the mercury standard for reproduction and comparison, by which means the advantages of both systems are happily combined, and much valuable labour is utilised; only, instead of expressing electrical quantities directly in absolute measure, the Congress has embodied a consistent system, based on the ohm, in which the units are of a value convenient for practical measurements. In this, which we must hereinafter know as the "practical system," as distinguished from the "absolute system," the units are named after leading physicists, the Ohm, Ampère, Volt, Coulomb, and Farad.

I would venture to suggest that two further units might, with advantage, be added to the system decided on by the International Congress at Paris. The first of these is the unit of magnetic quantity or pole. It is of much importance, and few will regard otherwise than with satisfaction the suggestion of Clausius that the unit should be called a "Weber," thus retaining a name most closely connected with electrical measurements, and only omitted by the Congress in order to avoid the risk of confusion in the magnitude of the unit current with which his name had been formerly associated.

As Clausius has shown, the unit of pole in absolute measure must be multiplied by the factor 10^8, in order to make the Weber consistent with the practical system. With greater diffidence I would submit two other units, which, I think, would be of considerable service in practical work. Firstly, the unit connecting heat measurements with the electrical system. Hitherto the unit of heat has been taken variously as the heat required to raise a pound of water at the freezing point through 1° F. or C., or, again, the heat necessary to raise a kilogramme of water 1° C. The inconvenience of such a unit so entirely arbitrary is sufficiently apparent to justify the introduction of one based on the electro-magnetic system, *i.e.*, heat generated in a second by the current of an Ampère flowing through the resistance of one Ohm. In absolute measure its value is 10^7 C.G.S. units, and assuming Joule's equivalent as 42,000,000, it is the heat necessary to raise ·238 grammes of water 1° C., or approximately 1-1000th

of the arbitrary unit of 1 lb. of water raised 1° C. Such a heat unit might with great propriety be called the Joule.

The last unit I should suggest adding to the list is that of power. The power conveyed by a current of an Ampère through the difference of potential of a Volt is the unit consistent with the practical system. It might be appropriately called a Watt, in honour of that master mind in mechanical science, James Watt. He it was who first had a clear physical conception of power, and gave a rational method of measuring it. A Watt then expresses the rate of an Ampère multiplied by a volt, whilst a horse-power is 746 Watts, and a cheval de vapeur 735. Accepting the Joule, the Watt can be briefly defined as a Joule per second.

The definition of the Joule which I have given leads, no doubt, to a somewhat small—perhaps inconveniently small—value to heat measurements; but the advantages of consistency with the other units appear to me to outweigh any inconvenience there may be in this respect. The complete system of electro-magnetic units would then be:—

(1) Weber,	unit of	magnetic quantity =	10 C.G.S. Units.
(2) Ohm	,,	,, resistance =	10^9 ,,
(3) Volt	,,	electromotive force =	10^8 ,,
(4) Ampère	,,	,, current =	10^{-1} ,,
(5) Coulomb	,,	,, quantity =	10^{-1} ,,
(6) Joule	,,	,, heat or work =	10^7 ,,
(7) Watt	,,	,, power =	10^7 ,,
(8) Farad	,,	,, capacity =	10^{-9} ,,

At the Paris Congress Sir W. Thomson suggested that the unit of magnetic field would be a useful addition, and pointed out that it would be proper to attach to it the name of Gauss, who first theoretically and practically reduced observations of terrestrial magnetism to absolute measure. It is a point for discussion as to what would be the definition of the Gauss, to keep it consistent with the other units. Defining it in the way perhaps most obvious, as the strength of field produced by a Weber at the distance of one centimetre, its value would be 10^8 C.G.S. units, but this is certainly inconveniently large, consequently I have considered it advisable to omit it from the list, and leave it in the form originally proposed by Sir W. Thomson, as the absolute unit of magnetic field.

(To be continued.)

NOTES ON ATMOSPHERIC ELECTRICITY.

[Paper read by C. MICHIE SMITH, B.Sc., F.R.S.E., Professor of Physical Science in the Madras Christian College, at the Meeting of Section A, on Wednesday, August 30th, 1882.]

BEFORE leaving for India in the end of 1876, it occurred to me that as almost nothing seemed to be known about atmospheric electricity in the tropics, it would be well if I could take with me the apparatus necessary for making observations on it. I accordingly communicated with Sir W. Thomson, who kindly obtained for me a grant from the British Association for a portable electrometer. This instrument I took with me, and the following are the results of the observations made with it. During the voyage a number of observations were made, but of those only two sets were of any special interest. The first of these was made in the Suez Canal, on December 22nd. At 8 a.m., at noon, and again at 8 p.m., the readings showed a negative electrification, of from three to eight divisions of the scale, the weather being entered as "fine and bright," and the wind as "S., very light," "E. by S., light breeze," "E.S.E., light," respectively; while readings taken at 1.30 p.m. and 7.30 p.m., gave a positive electrification of eight divisions on each occasion. This has considerable interest in connection with some observations made at Madras. The other set was made in the Red Sea during a rather violent squall. In this case the readings varied very rapidly from strong + to strong —, readings 1½ hours before having been + 18 divisions. The variations took place so rapidly that no quantitative observations could be made, and in a few minutes, when the squall had passed over, the readings were found to be much as before + 17 divisions. In Madras, a series of observations were made, extending from 17th January to 4th March, 1877. These were made at 8.30 a.m. and 6 p.m., and showed a wonderfully steady state of electrification, varying from a maximum of + 53 to + 19, with an average of + 33. The morning and evening readings usually agreed very closely. In every case the electrification was positive, and the weather very fine without any rain. During this time the electrometer had to be recharged every two or three days, an operation which, though very simple in this climate, is by no means so simple in a climate so moist as that of Madras. After a time I found it impossible to continue the observations at all, and sent the instrument home to see if it could be in any way modified so as to suit the climate. On its return, after a long delay, I found it leaked as badly as before, and so rendered observations almost impossible. The reason is doubtless to be found in the circumstance that the air of Madras is not only moist, but is also very full of small particles of salt, which are constantly being carried from the surf by the sea breeze. The glass of the jar soon gets coated with these particles, and no amount of simple drying will make the insulation good. That the fault did not lie in the jar itself I have tested since my return to this country, for I find that here the leakage is less than 1·5 per cent. per diem, while in Madras it was often over 30 per cent. per diem.

On account of these difficulties I was unable to make any long series of observations, but in July of 1881, I made a few that were specially interesting as being the only ones in which I have observed negative electrification in Madras, except during the thunderstorms. The observations were as follows:—

July.	p.m.			Reading.
5	1	Strong land wind.	Temp. 94° F.	—74
6	,,	,,	,,	—16
7	,,	,,	,,	0
,,	2·20	,,	,,	—15

In each case local showers within three or four hours. These observations are, of course, too few to form any theory upon, but those acquainted with the peculiar sensations produced by the land wind in Madras, will feel that the point is worth investigation, and I hope on my return to Madras to be able to take with me improved apparatus with which to continue the observations.

ON SECONDARY BATTERIES, WITH SPECIAL REFERENCE TO LOCAL ACTION.

[Paper read by Dr. GLADSTONE, F.R.S., before Section A, Friday, August 25th.]

THE high hopes that were originally entertained of the Planté battery and its various modifications have scarcely been realised as yet, and one main cause of this is to the extent to which their efficiency is apt to be reduced by local action. The positive element is always metallic lead, the negative element peroxide of lead, and the binary liquid dilute sulphuric acid. Now the peroxide of lead, which constitutes the negative plate, is itself supported by a sheet of lead, and both are immersed in acid. Voltaic action necessarily takes place, therefore, between the elements of which this plate is composed; the lead is converted into sulphate of lead, while the peroxide is reduced to protoxide, which immediately combines with some of the excess of acid to form sulphate of lead and water. As however this insoluble salt is produced on the surface of the metallic sheet, and of the peroxide crystals, a barrier to further action is speedily formed; but, as the amount of force which can be obtained from one of these cells depends upon the amount of peroxide that is capable of being reduced, the value of the cell is *pro tanto* diminished. This local action may have taken place to a great extent without its being recognised. On joining the negative and positive plates the current that instantly ensues is of almost the full strength, and the electromotive force is still 2·0 volts, or thereabouts. It is only when the cell has been allowed nearly to exhaust itself that the loss of power through the destruction of the peroxide makes itself evident by the smaller amount of work done.

This local action is not stopped, though it is probably diminished, by the discharge taking place between the negative plate and the positive one. It takes place also during the formation of the cell, as is evidenced by an absorption of oxygen greater than would be required merely for the oxidation of the minium used in Faure's process, and by the continuous absorption of a small quantity of oxygen for days after the main action is complete.

This defect of the existing secondary batteries is probably to be overcome by some modification of the elements employed in their construction.

(To be continued.)

ON SOME APPARATUS FOR USE IN CONNECTION WITH ELECTRIC LIGHT MEASUREMENT.

[Paper by ROBERT SABINE, C.E. Read before Section G, Aug. 29th.]

HAVING occasionally to make measurements requiring some degree of exactness of the electrical and photometric values of electric light systems, in reference to the power expended in maintaining them, I had for some time difficulty in finding apparatus specially adapted for this work, the electrical instruments which were suitable for continuous current systems being, as a rule, unsuitable for alternate currents. I was therefore induced to design some apparatus for my own use, which I have found convenient and sufficiently exact for practical purposes.

I. THE PHOTOMETER.

The absorption of light when passing through translucent media has hitherto been almost entirely unemployed for photometric purposes. Lampadius, it is true, suggested the reduction of any ordinary light to its vanishing point by means of thin sheets of horn, assuming that this vanishing-point might be taken as a fixed unit of intensity—a method which De Limency and Secretan proposed to modify by employing sheets of paper instead of horn—and Count Xavier de Maistre and Quetelet suggested the employment of wedges of blue glass for purposes of stellar photometry. But in neither instance was anything approaching to a practical photometer produced.

The photometer which I am about to describe is based upon the partial equalisation of any two lights under comparison, by interposing in the path of the rays of each light a sufficient thickness of absorbing material, the final adjustment being made by a slight alteration of the relative distances of the lights from the photometer.

Instead of comparing the lights directly with each other, I find that much better results are obtained by comparing them singly with a third light, which is constant.

This constant light I obtain by allowing the rays from a small portion of the bright part of a paraffine flame to pass through suitable diaphragms; the advantage of this method being that so long as the diaphragms are not too large, any trifling irregularity in the paraffine flame, through burning higher or lower, does not affect the small portion of the bright part which is employed, and therefore the utilised light is practically as nearly constant as possible. The form of apparatus which I use is shown in section in fig. 1, in which the photometer is placed, for convenience of illustration, vertically, as if measuring a light immediately above it. The graduated scale, a, a^1, upon which the photometer travels, turns upon a centre carried by a stand (not shown in the drawing), and can be elevated or depressed to any desired angle. The photometer consists of a square box, d, d, on one side of which is a draw-tube and eye-pi

lens, g; and on the other side a tube, f, carrying a collar by which the paraffine lamp, b, b, is supported, and may be kept in a vertical position at whatever angle the scale may be directed. The chimney of the paraffine lamp is of copper, and opposite to the bright part of the flame, is provided with a tube, c, in which are a thin pane of glass and two diaphragms, and at the back another tube, c^1, in which a dark glass is fitted for observing, from time to time, the flame, to ascertain that it is burning in the proper position.

At p_1 is a thin sheet of translucent material, part of its inner surface being observed direct by the eye at g.

The light to be measured is placed at a distance (under three feet if possible) beyond the end, a, of the scale, so that its rays fall upon the face of a thickness of translucent material, p, inserted in a suitable guide at the side of the photometer, its inner surface being observed

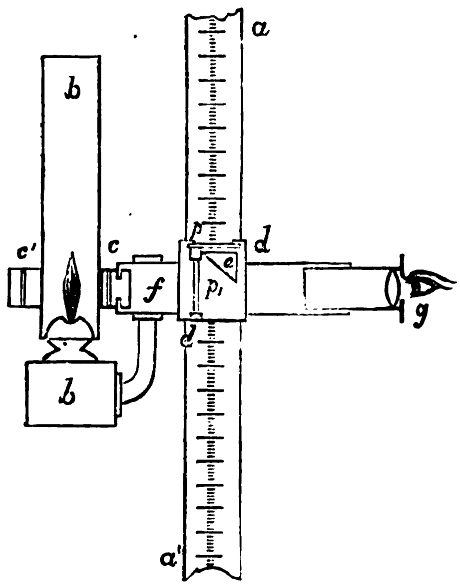


FIG. 1.

by the eye at g, reflected by the prism, e, which occupies half of the field of view. The thickness of the interposed translucent material, p, is adjusted until the illuminations of the two halves of the field of view are as nearly equal as this adjustment allows; then the distance between the light to be measured and the face of p is adjusted by causing the photometer, which is mounted on rollers, to travel on the scale until the two halves of the field of view are equally illuminated.

The illustration shows the photometer directed vertically upwards; but as the lamp may be turned with the collar which supports it, the scale may be placed horizontally or inclined at any desired angle upwards or downwards. In order to lessen the effect upon the eye of slight differences of colour between the lights to be compared, there are inserted just at the top and bottom of the line in which the two halves of the field of view meet, small strips of highly coloured glass. The effect of the presence of these, when I am observing, is to render the eye partly unconscious of small differences of tint of the middle portions of the field of view, without reducing its sensitiveness for appreciating the balance of illuminating effect.

The comparison with the horizontal light of a standard candle is done by placing the photometer horizontally and putting the candle at the end, a, of the scale, reducing at the same time the thickness of the translucent material, p, until a balance is nearly obtained, and finally adjusting by sliding the photometer along the scale.

The intensity of the light which penetrates from the paraffine lamp to the inner surface of the translucent sheet, p_1, and which is the constant of comparison, we will call λ. We may assume that of the light which falls upon the surface, p, the fraction which is scattered and reflected bears to it a constant relation, r.

Let L be the illuminating power of the measured light in the direction of the photometer, n the thickness of absorbing material, and D the distance of the source of light from p. Then the light which reaches the surface of p when a balance is obtained will be:—

$$\lambda = \frac{(1 - r)\,\mathrm{L}\,m^n}{\mathrm{D}^2},$$

m being the co-efficient of translucency of the absorbent body, p; that is to say, the intensity of light which succeeds in reaching the inner surface of a unit thickness of p, when a unit intensity of light enters the outer surface.

Similarly, for the standard candle, the illuminating power of which is l, its distance, d, and the interposed thick of the same translucent material, n_1:—

$$\lambda = \frac{(1 - r)\,l\,m^{n_1}}{d^2},$$

the relation of these two lights is, therefore:—

$$\frac{\mathrm{L}}{l} = \left(\frac{\mathrm{D}}{d}\right)^2 m^{n_1 - n}$$

it being assumed that the light of the paraffine lamp has remained constant during the two observations, and that the atmosphere has not acted as an absorbent.

The co-efficient of translucency of the interposed absorbent material must, of course, be very carefully determined, because upon the value of this co-efficient being exactly known depends the accuracy of the results obtained as much as upon the accuracy of the final adjustment of distance.

This co-efficient I determine by employing a strong steady light, and taking observations of distance first with one, then several (say, n) thicknesses of the material.

If the observed distance with one thickness is d_1, and that with n thicknesses is d_n:—

$$m = \left(\frac{d_n}{d_1}\right)^{\frac{2}{n-1}}.$$

I find that the readiest way is to take alternately the distances with one and three thicknesses, because then

$$m = \frac{d_3}{d_1}$$

a simple relation which saves calculation.

The comparison of one with two thicknesses was found to be objectionable, as any error of observation was exaggerated, whereas when more than three were taken for the co-efficient the illumination of the field became weakened, and the observations were less accurate.

It is not necessary that the translucent body at p_1 should be either of the same quality, tint, or thickness, as that used at p, as it is simply intended to provide a constantly illuminated surface for comparison; but the thicknesses of the material used at p must be carefully selected, and must be as uniform as the eye is capable of detecting. The material which I have found to be most convenient for use as an absorbent, consists of thin plain photographic paper, which is very uniform in texture, and is easily procurable.

In an earlier form of this photometer, the comparison was made direct with a standard candle, by enclosing the latter in a candle-holder consisting of a closely-fitting tube, furnished with a spring, which pressed the candle up against a top rim, and maintained it at a constant level in a suitable dark lanthorn.

It was found, however, that a candle so circumstanced always gave a reduced light, and that other lights compared with it appeared to be exaggerated in photometric value; moreover, the difference of colour between the light of a candle and that of most electric arc lamps, is very striking, while the colour of a paraffine flame is between the two, and the difference, therefore, between it and either the candle or electric light is less embarrassing.

When it is desired to employ Schwendler's method of observing the illuminated surfaces through coloured glasses, I place them before the eye-piece, g.

II. THE CURRENT DYNAMOMETER.

The current dynamometer is constructed to be equally applicable to continuous and alternate currents.

It consists of two circular flat coils of thick copper, a and b, as shown in outline in fig. 2.

One of the coils, a, is carried on a beam, together with a counter-weight, by a bifilar suspension. This suspension is done by a thin silk thread, the two ends of which are fixed to a torsion-head at d,

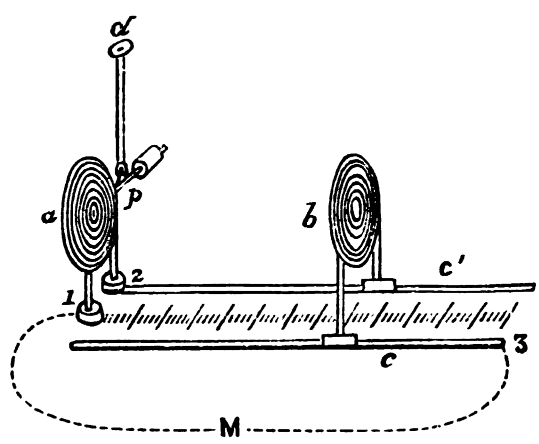

FIG. 2.

its middle portion passing under a small friction pulley, p, attached to the beam. By this means the strain upon both sides of the bifilar thread is equal. The ends of the movable coil, a, are amalgamated, and dip into two suitable mercury cups (1 and 2). In the position of rest, the torsion-head of the bifilar suspension is turned so that the plane of the coil, a, forms an angle of 5° to 10°, with the plane of the coil, b; its angular position being observed by a mirror attached to the suspended coil, which projects a spot of light upon a scale placed at a constant distance. The second flat coil, b, is mounted upon grooved copper feet, which slide upon two copper rails, c, c^1, keeping coil b at right angles to the rails and facing coil a, but at distances which may be readily varied.

The dynamometer is inserted in the circuit whose current is to be measured, between terminals connected with the points 1 and 3. The current from M enters the system at the terminal connected with the mercury cup (1), circulates (right-handed) through the suspended coil, a, which it leaves by the mercury cup (2), passes along the c^1, to the sliding coil, b, in which it circulates (left-handed), passes the rail, c, and so back to the circuit.

The repulsion which takes place between the coils, results, of course, in the deflection of the suspended coil to a greater degree, according to the strength of the current and the

between the coils. If this deflection is insufficient to place the coil, *a*, parallel to coil, *b*, the latter is slid along the rails nearer to *a*; but if the repulsion cause *a* to be deflected beyond its parallel position, coil *b* is drawn back until the light point settles to the zero of the scale.

The sluggishness of the mercury in the cups is utilised to check any continued oscillation.

The scale of the instrument is placed between the rails. It was calibrated by comparison with a tangent galvanometer, the position of the sliding coil, *b*, when the parallel position of the suspended coil was obtained, being marked for each ampère of current; and it was found that, beyond one ampère, the distance was practically proportional to the current; but below one ampère this proportion did not obtain, probably due to want of symmetry in the coils themselves.

As the deflection of the suspended coil is always the same, the repelling force acting upon it is constant; and if this force is directly proportional to the square of the current, and inversely to the square of the distance between the coils, it would follow that the current and distance should be directly proportional to each other.

The resistance to deflection of the suspended coil must, of course, be kept as constant as possible. This I have attempted by using unspun silk for the bifilar suspension, and putting the threads at a sufficient distance apart to cause the resistance to deflection to be due more to the lifting of the coil than to the torsion proper of the threads.

By making the current go through the two coils in derived circuit instead of in series, the sensitiveness becomes reduced to half; the range of the scale being proportionately increased. For very strong currents the range of the scale can be increased to any extent by properly arranged shunts.

When measuring very strong currents the disturbing effect of the earth's magnetism has to be considered. In order to allow for this, before making an observation I place a coil of wire of the same resistance as one of the working coils, but double-wound, upon the rails in place of *b*. This dummy coil has no deflecting effect upon the suspended coil, but renders the current moving through it the same as when *b* is in its place. When this is done the effect of the earth's magnetism is to cause a slight deflection of the suspended coil from its position of rest, to which it is then re-adjusted by turning the torsion-head.

So far I have found this method to be convenient, although the apparatus I use is home-made, it has the advantage of being strictly a zero method, and the instrument is not encumbered with any table for the reduction of observations.

III. THE POTENTIAL DYNAMOMETER AND RESISTANCE MEASURER COMBINED.

This instrument is designed to fulfil a double duty, and as a potential dynamometer is equally available for continuous and for alternate currents.

It consists of two circular coils of moderately fine copper wire, one of which is held by a bifilar wire suspension inside the other, as in Weber's well-known dynamometer. When required, however, to be used as a galvanometer, the suspended coil can be readily removed and replaced by a magnet needle.

When used as a dynamometer with a potential-difference of one Daniell between the terminals, the suspended coil is deflected to between 100 and 150 divisions of a reflected light point falling upon a scale at a distance of 100 centimetres. This reading, which remains very constant, can, however, be adjusted for a greater or less degree of sensitiveness by altering the distance apart of the bifilar suspending wires.

The reading with one Daniell potential-difference is the constant of the dynamometer, and is obtained by inserting between the terminals a Daniell cell having a resistance sufficiently small that it may be neglected without appreciable error.

When any greater potential-difference is to be measured, an adjustable resistance is inserted in the circuit in order to reduce the current (and deflection) to the same value as the constant. For instance, if a potential-difference, x, of an electric arc is to be measured, the terminals of the lamp, or connections from the carbons, are inserted, with an adjustable resistance which is gradually reduced to r, so as to reproduce the constant deflection of the light-point. The constant current is then represented by two equations:—

$$c = \frac{e}{\rho}$$

ρ being the resistance of the dynamometer wires, and e, volts, the electromotive force of the Daniell, and:—

$$c = \frac{x}{r + \rho},$$

assuming that the resistance of the arc may be neglected, as it is very small in comparison with $r + \rho$.

The electromotive force of the arc is therefore:—

$$x = e\left(\frac{r}{\rho} + 1\right) \text{ volts.}$$

The effect of the earth's magnetism upon the suspended coil is, of course, entirely eliminated, the current being the same in each observation.

The resistance box, which I use in connection with this dynamometer, is constructed with adjustable resistances between one and 100,000 ohms, and has in addition the usual proportion-coils of a Wheatstone bridge.

When it is required to measure the wire resistance of a circuit, this resistance box is employed as a Wheatstone bridge. The suspended coil of the dynamometer is removed, and a magnet-needle inserted in the centre of the stationary coil, so as to readily provide a galvanometer which is sufficiently sensitive for measuring small resistances with the aid of the constant Daniell cell, thus avoiding the necessity of providing separate instruments for this purpose.

IV. THE MEAN PRESSURE-INDICATOR.

The determination of the horse-power performed by the steam-engine is usually made by taking diagrams with a Richard's modification of Watt's indicator. There are, however, some objections to the use of this instrument for this purpose, arising from the necessity of special fittings, besides the fact that these diagrams, obtained at considerable trouble, give more information than is wanted for the object in view.

The horse-power is calculated only from the mean pressure, which I have endeavoured to arrive at in a more simple way. Instead of taking indicator-diagrams, I have obtained very good results with a simple Bourdon pressure-gauge, so arranged that the mean pressure at either end of the cylinder can be read off at once, and the horse-power obtained at any moment with very little trouble.

For this purpose I attach to each end of the cylinder a pressure gauge, the pipe leading to which is throttled sufficiently to allow only of a small entry and exit of steam at each stroke. This throttling may be carried to such an extent that the pointer of the gauge rises comparatively slowly to the mean pressure, above and below which it makes small oscillations.

In the arrangement of the gauge, the attachment to the blow-off cock of the cylinder is conveniently made by a short length of thick india-rubber tubing, strengthened by a double serving of tape, and lashed. Between this and the gauge, I insert a tube of brass containing, in a socket coupling, a screw plug, through which a small hole is bored. Every precaution has, of course, to be taken to prevent condensation of steam in the throttle or in its immediate neighbourhood. For this purpose I keep the throttle-tube at a temperature considerably above the temperature of the steam by placing the flame of a lamp underneath it. Between the throttle and the pressure gauge is a small blow-off cock. Before observing the mean pressure this cock is opened, and steam blown through. It is then closed, and the pointer of the gauge rises by a series of jerks up to the mean pressure, about which it oscillates through a small arc, the mean point being easily observed.

ON A NEW ARC ELECTRIC LAMP.

By W. H. PREECE, F.R.S.

[Read before Section G of British Association.]

ELECTRIC lamps on the arc principle are as numerous as the trees in the forest and it is somewhat fresh to come upon something that is novel. In these lamps the carbons are consumed as the current flows, and it is the variation in that consumption which occasions the flickering and irregularity of the light that is so irritating to the eyes. Special mechanical contrivances or regulators have to be used to com-

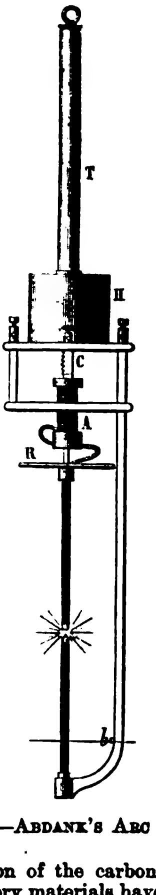

FIG. 1.—ABDANK'S ARC LAMP.

pensate for this destruction of the carbons, as in the Siemens and Brush type, or else refractory materials have to be combined with the carbons, as in the Jablochkoff candle and in the Lampe-Soleil. The steadiness of the light depends upon the regularity with which the carbons are moved towards each other as they are consumed, so as to maintain the electric resistance a constant quantity. Each lamp must have a certain elasticity of regulation of its own to prevent

irregularities from the variable materials of carbon used, and from variations in the current itself and in the machinery.

In all the electric lamps, except the Brockie, the regulator is in the lamp itself. In the Brockie system the regulation is automatic, and is made at certain rapid intervals by the motor engine. This causes a periodic blinking that is detrimental to this lamp for internal illumination.

M. Abdank, the inventor of the system which I have the pleasure of bringing before the Section, separates his regulator from his lamp. The regulator may be fixed anywhere within easy inspection and manipulation, and away from disturbing influence in the lamp. The lamp can be fixed in any inaccessible place.

The Lamp (figs. 1, 2, 3).

The bottom or negative carbon is fixed, but the top or positive carbon is movable in a vertical line. It is screwed at the point, C, to a brass rod, T (fig. 2), which moves freely inside the tubular core of

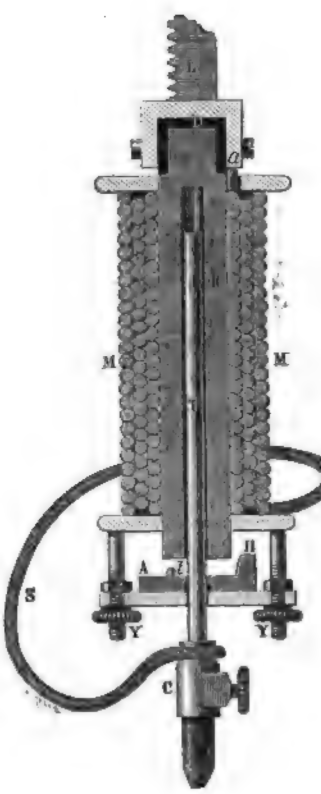

FIG. 2.—ABDANK'S ARC LAMP.

an electro-magnet, E. This rod is clutched and lifted by the soft iron armature, A, B, when a current passes through the coil, M, M. The mass of the iron in the armature is distributed so that the greater portion is at one end, B, much nearer the pole than the other end, hence this portion is attracted first, the armature assumes an inclined position maintained by a brass button, *t*, which prevents any adhesion between the armature and the core of the electro-magnet. The electric connection between the carbon and the coil of the electro-magnet is maintained by the flexible wire, S.

The electro-magnet, A (fig. 1), is fixed to a long and heavy rack, C, which falls by its own weight and by the weight of the electro-magnet and carbon fixed to it. The length of the rack is equal to the length of the two carbons. The fall of the rack is controlled by a friction-brake, B (fig. 3), which acts upon the last of a train of three wheels

FIG. 3.
SHOWING FRICTION BRAKE.

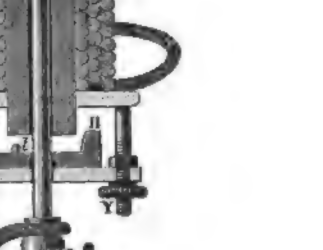

FIG. 5.
LAMPS IN SERIES.

put in motion by the above weight. The brake, B, is fixed at one end of a lever, B A, the other end carrying an easily-adjusted soft iron armature, F, by three screws. This armature is attracted by the electro-magnet, E (whose resistance is 1,200 ohms), whenever a current circulates through it. The length of play is regulated by the screw, V. The spring, L, applies tension to the brake.

The Regulator.

This consists of a balance and cut-off. The balance (figs. 4 and 6) is made with two solenoids, S, S', whose relative distance is adjustable. S conveys the main current, and is wound with thick wire, having practically no resistance, and S' is traversed by a shunt current and is wound with fine wire, having a resistance of 600 ohms. In the axes of these two coils a small and light iron tube (2 mm. diameter and 60 mm. length) freely moves in a vertical line between two guides. When magnetised, it has one pole in the middle and the other at each end. The upward motion is controlled by the spring, N T. This spring rests upon the screw, H, with which it makes contact by platinum electrodes. This contact is broken whenever the little iron rod strikes the spring, N T.

The positive lead from the dynamo is attached to the terminal, B, then passed through the coil, S, to the terminal, B', whence it proceeds to the lamp. The negative lead is attached to terminal, A, and thence to the lamp.

The shunt which passes through the fine coil, S, commences at the

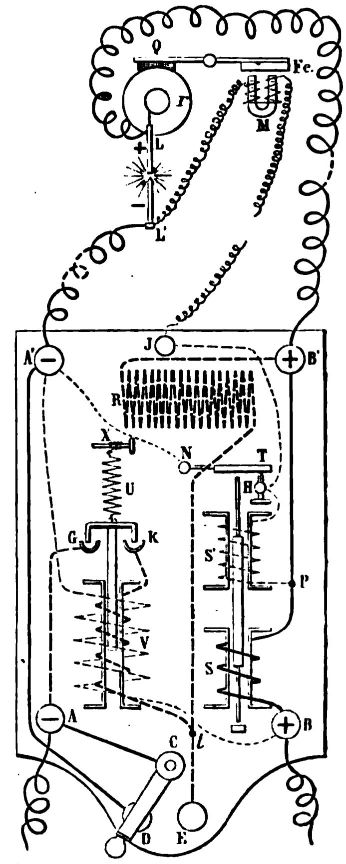

FIG. 4.—ABDANK'S ARC LAMP. THE BALANCE AND CUT-OFF.

point, P; the other end is fixed to the screw, H, whence it has two paths, the one offering no resistance through the spring, T N, to the upper negative terminal, A', the other through the terminal, J, to the electro-magnet of the brake, M, and thence to the negative terminal of the lamp, L'.

The Cut-off.

The last part of the apparatus to be described is the "cut-off," which is used when there are several lamps in series. It is brought into play by the switch, C D, which can be placed at E or D. When it is at E, the negative terminal, A, is in communication with the positive terminal, B, through the resistance, R, which equals the resistance of the lamp, which is therefore out of circuit. When it is at D, the cut-off acts automatically to do the same thing when required. This is done by a solenoid, V, which has two coils: the one of thick wire offering no resistance, and the other of 2,000 ohms resistance. The fine wire connects the terminals, A and B. The solenoid has a movable soft iron core suspended by the spring, U. It has a cross-piece of iron which can dip into two mercury cups, G and K, when the core is sucked into the solenoid. When this is the case, which happens when any accident occurs to the lamp, the terminal, A, is placed in connection with the terminal, B, through the thick wire of V and the resistance, R, in the same way as it was done by the switch, C D.

Electrical arrangement.

The mode in which several lamps are connected up in series is shown by fig. 5. The lead, +, is connected to B of the balance; it then passes to the lamp, L, returning to the balance and then proceeds to each other lamp, returning finally to the negative pole of the machine. When the current enters the balance it passes through the coil, S, magnetising the iron core and drawing it downwards. It then passes to the lamp, L L', through the carbons, then returns to the balance and proceeds back to the negative terminal of the machine. A small portion of the current is shunted off at the point, P, passing through the coil, S', through the contact spring, T N, to the terminal, A', and drawing the iron core in opposition to S. The carbons are in contact, but in passing through the lamp the current magnetises electro-magnet, M (fig. 2), which attracts the armature, A B, that bites

and lifts up the rod, T, with the upper carbon a definite and fixed distance that is easily regulated by the screws, Y Y. The arc, then, is formed, and will continue to burn steadily as long as the current remains constant. But the instant the current falls, due to the increased resistance of the arc, a greater proportion passes through the shunt, S' (fig. 4), increasing its magnetic moment on the iron core, while that of S is diminishing. The result is that a moment arrives when equilibrium is destroyed, the iron rod strikes smartly and sharply upon the spring, N T, contact between T and H is broken, and the current passes through the electro-magnet of the brake in the lamp. The brake is released for an instant, the carbons approach each other, but the same rupture of contact introduces in the shunt a new method of considerable magnitude—viz., 1,200 ohms—that of the electro-magnet of the brake. Then the strength of the shunt diminishes considerably, and the solenoid, G, recovers briskly its drawing power upon the rod and contact is restored. The carbons approach during these periods only about ·01 to ·02 millimetres; if this is not sufficient to restore equilibrium it is repeated continually till equilibrium is obtained; the result is that the carbon is continually falling by a motion invisible to the eye, but sufficient to provide for the consumption of the carbons.

The contact between N T and H is never completely broken; the sparks are very feeble and the contacts do not oxidise. The resistances

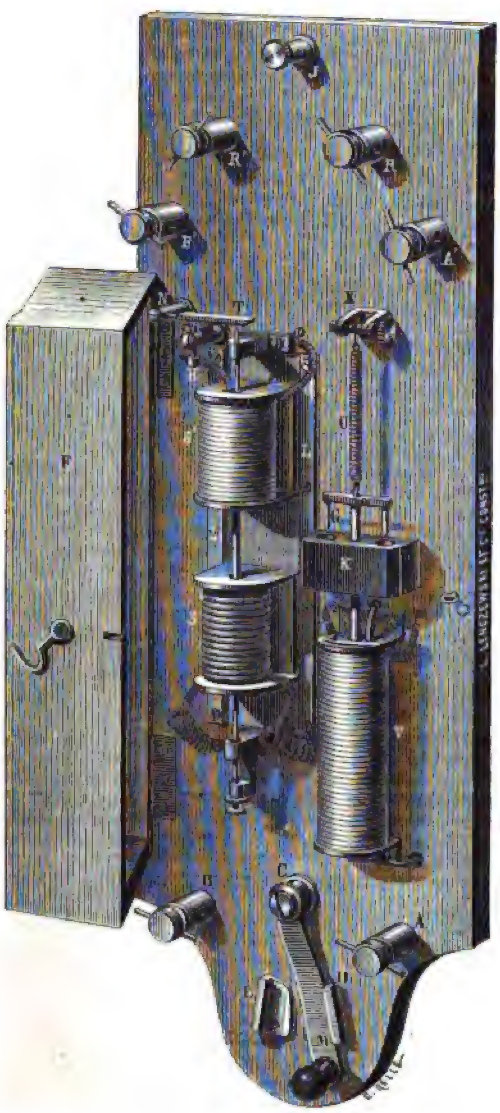

FIG. 6.—ABDANK'S ARC LAMP. PLAN OF BALANCE AND CUT-OFF.

inserted are so considerable that heating cannot occur, while the portion of the current abstracted for the control is so small that it may be neglected. The balance acts precisely like the key of a Morse machine, and the brake precisely like the sounder receiver so well known in telegraphy. It emits the same kind of sound and acts automatically like a skilled and faithful telegraphist. This regulation by very small and short successive steps offers several advantages. 1st. It is imperceptible to the eye. 2nd. It does not affect the main current. 3rd. Any sudden instantaneous variation of the main current does not allow a too near approach of the carbon points.

Let now an accident occur, for instance, a carbon is broken. At once the automatic cut-off acts, the current passes through the resistance, R, instead of passing through the lamp. The current through the fine coil is suddenly increased, the rod is drawn in, contact is made at G and X, and the current is sent through the resistance, R. As soon as contact is again made by the carbons the current in the coil, S, is increased, that in V diminished, and the antagonistic spring, U, breaks the contact at G and X. The rupture of the light is almost invisible, because the relighting is so brisk and sharp. I have seen this lamp in action, and its constancy and steadiness leaves nothing to be desired.

REPORT OF THE COMMITTEE ON ELECTRICAL STANDARDS.

[By LORD RAYLEIGH. At Section A, Tuesday, August 29, 1882.]

IN this matter I am only the mouthpiece of the committee. I have had very little to do with the work of which I am now to give an account. Almost the only matter in which progress has been made has been in experiments upon the effect of annealing upon electrical resistance of various wires of various metals, and in particular upon the temperature co-efficients, *i.e.*, the change which the resistance of the wire undergoes when the temperature is altered. These experiments have led to rather unexpected results, in the direction of showing that these effects are so much greater than is generally supposed, and that therefore there is greater difficulty than is usually thought of in the way of obtaining thoroughly satisfactory resistance standards. The following are some examples of the results obtained. In a wire of German silver, drawn so as to be extremely hard and brittle, the percentage of variation of resistance for one degree was ·0296. After annealing, the percentage of variation for the same wire was ·0421, showing a very large increase. In the case of steel, as might have been expected, the results are even more marked. For a steel wire, thoroughly hardened and tempered in paraffine wax, at a temperature of 230°, the percentage of variation of resistance for one degree was found to be ·267. In the same wire when annealed the percentage variation was found to be ·316. At 9° Centigrade the ratio of the absolute resistance of this wire in the hard state to that of the same wire when annealed, was 1·229. The next result relates to a wire of platinum and silver alloy. A piece of wire from a particular bar of the alloy was hardened by being drawn down through a couple of holes in a draw-plate, and in this state the variation of resistance was ·0255 per cent. per degree. After annealing the variation of resistance was ·0258. The same wire was next placed in an iron tube filled up with sand, and left all night in the fire. After this treatment, the variation of resistance was ·0344. Another specimen of platinum and silver alloy, after being heated to a very high degree and allowed to cool slowly, the variation of resistance was ·095, and the wire was as soft as pure silver and very fragile. When heated to redness and cooled suddenly by the application of water, the variation of resistance was ·076; when the wire was drawn down two or three holes in the draw-plate it was ·073, showing that it had not, even after re-heating, recovered its original condition. This indicates the connection between the temperature co-efficient of wires and the degree of hardness such as to re-open the question as to the nature of a trustworthy material for a proper standard of resistance. The experiments are being continued by Mr. Taylor and Dr. Muirhead. There are one or two points to which I should like to draw the attention of the section in connection with this subject of the comparison of resistance of the standards. At the Cavendish Laboratory at Cambridge, where the original standards constructed by the Committee of this Association are placed, we had no difficulty at all in comparing single units with these standards, which comparison was effected with very great accuracy, the principal source of error being really in determining the actual temperature of the wire at the time of the operation. However, in the case of the platinum and silver standards the sensitiveness to temperature is not very great, and the practical resistance, including the error due to temperature, can be made with the accuracy of one in 10,000 without any difficulty. For practical purposes it is not enough to have certified copies of the unit, but we must have also correct copies of the multiples of the unit, particularly the 10 and the 100. The question arises how these multiples can be best constructed. Hitherto the procedure has been to arrive at the higher multiples by starting with a single unit, making another like it, then joining these and comparing the two with the one, then making another like the two, and so on, and thus build up the standard, say, of ten. But the process requires the aid of several intermediate coils if the object is merely to pass from one to the ten; and these intermediate observations have to be made with the highest accuracy. And, besides, it is a very tedious operation putting the coils together, and requires careful attention to the temperature. My object is to describe a method by which this object of passing from one to ten can be attained, but one more accurate than has been the case in the procedure hitherto. The method turns upon this principle:—I arranged three coils of German silver wire, each to have a resistance of about three units. When these three are placed in multiple arc they formed the resultant, as a single can be compared with the standard single; when, on the other hand, the three are placed in series, of course they have formed an aggregate of nine, which, by the addition of the original standard single, can be brought up to ten. In that way we require rather fewer intermediate coils. But that is not the main advantage. In this process of arcing we do not depend upon the accuracy of the threes which we use in the process. The principle upon which that depends is that if the sum of three resistances be given, then the resistance in multiple arc, when the three are placed in multiple arc, will be the maximum when the three are all equal. And although the three may not be quite rigorously equal, still the resistance in multiple arc is exceedingly near to the truth. All that remains then is to contrive a simple method of making the observations so that the two comparisons can be made to follow one another as quickly as possible. The first comparison consists in putting the three coils in multiple arc, and then comparing them with the standard single; and secondly, putting them in series, and then comparing the ten, or whatever you have arrived at, with the standard ten, which it is the object to test.

There are strips of very long copper plates placed between a planed board. Holes penetrate to the copper plates, and into these mercury is poured. These are the electrodes by which you can make

connection with the instrument. The three holes in which these are arranged are coupled with the single piece of brass tube. The six ends of the coils are connected with these six legs of copper, which project downwards and form the six legs of instrument. Therefore by this means we have the three coils in multiple arc and a resistance nine times less than when combined in series. The next part of the operation consists in displacing the set of three coils laterally, so that from being joined in multiple arc they are now joined in series. The electric current passes to the first cup, then through one of the coils into the lower part of the other, passing along the board to the left hand till it has passed through the whole in series. By this means, then, we have a connection made with the standard single, so that by one simple observation on one multiple arc and a single you can compare the resistance of the three coils with that of the standard single itself. Of course the resistance will not vary much in one experiment. It is therefore of advantage to make the one operation follow the other as quickly as possible, and allow little time for temperature change to enter, and in this way it is extremely easy to compare a 10 or a single with any other auxiliary coils than themselves. It is ready for use at any time. In testing a very rough accuracy is all that is wanted in the component coils. Any error arising from the use of the apparatus would be immaterial. I think the same method might be advantageously used to pass up by hundreds, that is, by using a resistance of 30 instead of a resistance of three, which when put in series will give 90, and then by the addition of the original 10 you will get 100.

APPLICATION OF ELECTRICITY TO THE RAISING OF THE WATER SUPPLY FOR THE TOWN OF LA ROCHELLE.

SINCE 1864 the town of La Rochelle has been supplied by a canal, which conducts the waters from the Lafont spring by an aqueduct into a subterranean reservoir, from whence two vertical balance machines of the Tarcot system, of 15 horse-power each, raise them to the water tower placed upon the culminating point of the town, at a height of about 20 metres. After thirteen years' service the level of the waters has fallen below the bed of the aqueduct supplying the reservoir. It therefore became necessary to hollow out a second gallery at two metres below this bed, and to raise the water from this gallery into the aqueduct leading to the reservoir by means of a rotary pump. This rotary pump is placed at 800 metres from the raising machine, and was actuated by a small separate locomotive, which was very expensive to work, and necessitated the continual presence of two men entirely occupied with this separate machine. Things were thus when M. Groc, Director of the La Rochelle Waterworks, conceived the ingenious idea of utilising the surplus motive force available upon elevating machines for working the rotary pump by means of an electric transmission of power to a distance.

This idea has been realised and the system has been in continual use since the month of July, 1881, without presenting the least difficulty and without interruption.

The transmission is performed by the aid of two Gramme machines with flat inductors of the pattern called "5-lighters." The generator makes 1,300 revolutions, the receiver about 800. This speed varies, moreover, a little with the level of the water in the lower gallery, a level which varies the work produced by the pump.

The line which connects the two machines is aerial; it is supported upon telegraph poles, and is 800 metres long. It forms a complete closed circuit. Each of the conductors is composed of two iron wires, of six millimetres diameter, fixed upon porcelain insulators, connected at intervals by transverse wires. The result is that if one of the wires is broken at any point whatever, the whole current only traverses the remaining wire over a length equal to the distance which separates two transverse joints of the double wire, the increase of resistance which ensues is then very small, and practically insensible. The line is represented by a double wire of six millimetres diameter ($\frac{1}{4}$ inch), and 1,600 metres long. Its resistance is about 3·5 ohms.

The work produced by the pump, in raising water, is equal to 140 cubic metres per hour raised to a height of two metres, that is to say, a little more than one horse-power. The force actually transmitted is about two horse-power. The work of the rotary pump in raising water is equal to one-tenth of that produced by the raising machines; the expenditure of steam is increased about one-sixth by the putting in action of the rotary pump. This is an insignificant expenditure in consideration of the special conditions of the installation. One workman only is required, placed near the pump, to oil the dynamo-electric machine and the pump. It will even be possible to dispense with him by providing the apparatus with oiling mechanism of sufficient capacity. One visit each day before the setting in motion will then make sure of the operation of the system without special supervision.

The motion of the pump is given by friction; to this end the dynamo-electric machine oscillates around a horizontal axis parallel to its own, placed at the lower part of the building. Its axle bears two pulleys, the rims of which are covered with leather, placed opposite two pulleys of a larger diameter placed upon a fixed arbor. By means of a manipulating lever, the axle of the machine is drawn towards or away from the fixed axle which controls the rotary pump by means of a transmission by pulleys and belts. The pressure of the friction pulleys is regulated by means of a manipulating lever kept in its place by a screw.

To put it in motion and also stop it, we begin by drawing away the transmitting motor, in such a manner that it turns freely.

Thus any extra current at the moment of stoppage when the circuit is interrupted is avoided, and any sudden shock at the moment of setting in motion. This is a most interesting and most suitable application of the transmission of power to a distance. No means of transmission at present known would have solved the problem with so much simplicity and elegance. We are glad to call attention to such applications, for they show much better than all the theories in the world, what powerful resources electricity offers to us when we know how to make judicious use of it.

NEW PROCESS FOR THE RAPID FORMATION OF SECONDARY COUPLES WITH PLATES OF LEAD.

WE know that the method employed for a long time by M. Planté for forming accumulators consisted of a sort of electro-chemical tanning of the plates produced by the passage of the current into the couple several times in reversed directions, taking care to allow intervals of repose between each change of direction.

This method gives layers of peroxide of lead and of lead reduced to a crystalline state adhering perfectly to the remainder of the plate which is not attacked, but it requires a tolerably long time, especially at the commencement.

To facilitate the attacking of the lead by the action of the primary current, and to accelerate the formation, M. Planté has made experiments and discovered that good results can be obtained by raising the temperature of the liquid containing the secondary couples, sometimes beforehand, sometimes during the action of the current.

The employment of heat presents, however, some difficulties in practice. M. Planté has had recourse in this case to another process, which has given him very satisfactory results, and which he has communicated to the Académie des Sciences of Paris at its sitting on the 28th August last.

This process consists of simply submitting the secondary couples to a sort of thorough scraping by means of nitric acid diluted with half its volume of water, and leaving them immersed in this liquid during 24 or 48 hours. The couples are then emptied, washed very thoroughly, refilled with water acidulated with 1-10th of sulphuric acid, and submitted to the action of the primary current. This prolonged immersion in diluted nitric acid produces the dissolution of a portion of the lead plates, but their thickness is not sensibly diminished by it. The metallic porosity produced by the nitric acid causes the ulterior electro-chemical action of the current to be exercised not only on the surface of the plates, but also on their interior; it creates new molecular intervals, and consequently facilitates the formation of the plates, considerably shortening its duration. In fact, the secondary couples thus treated can furnish, after three or four changes in the direction of the primary current, discharges of long duration, whilst, without the previous action of the nitric acid, it could only give the same results after several months' formation.

Accumulators prepared by this method seem, therefore, to present at once the advantages of couples of lead plates; that is to say, a good adherence of the deposits and the absence of the felt which maintains the minium upon the plates of the Faure couples, and at the same time the advantage peculiar hitherto to the Faure couples; that is to say, a rapid formation—a condition indispensable with accumulators intended for industrial application. It would be interesting to make new and careful comparisons between the last models of M. Faure and the new apparatus of rapid formation of M. Planté, as much from the point of view of rapidity of formation as of capacity of storage and of their effective duration in continual service.

ASSOCIATION FRANÇAISE POUR L'AVANCEMENT DES SCIENCES.

(From our own Correspondent.)

MEETING AT LA ROCHELLE.

PHYSICAL SECTION.

SITTING OF THE 28TH AUGUST, 1882—*(continued)*.

APPARATUS FOR OBSERVING THE DIRECTION AND RAPIDITY OF LIQUID CURRENTS AND PARTICULARLY OF MARINE CURRENTS.

By M. BONNEAU.

THE apparatus presented by the author to the Association Française is an improvement on that which was shown at the electrical exhibition at Paris. M. Bonneau has added to it a registering system which will enable the variations in speed and direction of marine currents to be followed continuously. We shall shortly have occasion to describe it with the assistance of figures.

ON THE DISTRIBUTION OF ELECTRICITY.

By M. DEBRUN, Professor of Physics at the Lycée of Pau.

The system proposed by M. Debrun consists in inserting a[illegible]mulators between the producer and consumer to prov[illegible] accidental stoppage of the machine. The distribution mus[illegible] out under constant pressure, the accumulators disposed i[illegible] branch of the circuit of distribution. The branch does not rece[illegible] the current

directly from the main channels of distribution, but from the accumulators always in communication with the main circuit, except in cases when, by accident, the production ceases for a given time; an automatic interrupter then separates the accumulators from the main circuit, and these continue to supply the consuming apparatus, lamps, motors, &c.

The electricity is measured by passing a derivation of the current into an electrolytic vat containing cyanide of silver, and by weighing the silver deposited at the end of a given time.

To maintain a constant distribution pressure, the needle of a fine wire galvanometer, placed in communication with the terminals of the machine, closes the circuit upon two bells of a different pitch, according as the electromotive force is greater or less than its normal value. The attendant thus warned can then restore things to the normal state by altering the speed of the machines or their excitation.

NEW SYSTEM OF ELECTRIC GENERATING APPARATUS.

By Dr. BRARD, of La Rochelle.

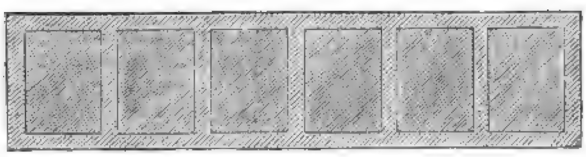
The object which M. Brard has in view in his researches is to produce an apparatus capable of transforming heat into electricity without having recourse to the complications presented by dynamo-electric machines which have been hitherto inapplicable for domestic illumination; M. Brard wishes to produce a veritable electro-generative stove, furnishing at the same time heat, light, and electricity. After having demonstrated by his experiment that thermo-electric batteries have on one hand only a feeble production, and on the other hand are soon rendered useless under the action of heat, M. Brard thinks he has found the solution of the difficulty in a thermo-chemical battery, in which the current is produced by chemical action, the combustion of carbon, under the influence of an elevated temperature produced by a special method, by the oxidising action of nitrate of potash or soda. It forms thus a veritable thermo-chemical battery, analogous to the ordinary batteries in which the oxidising of the carbon takes the place of the oxidising of the zinc and the nitrate of potash of the oxidising body. The carbon is, therefore, the negative pole, and the nitrate the positive pole of the element.

M. Brard alluded, in reference to his labours, to the experiments of Antoine-César Becquerel in 1855, and those more recently made by M. Paul Jablochkoff in 1877; he has, however, gone further than his antecedents in this way, for he has presented to the association the principal features of an apparatus actually in construction, and showed some electro-generative slabs which we are about to describe, reserving the description of the complete generator until it has been tried, and until it has undergone certain modifications which the experiments will suggest.

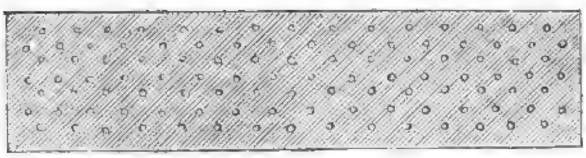
Electro-generative Slab.—The electro-generative slab may be defined as *a piece of prepared carbon which, when thrown into the fire, produces electricity by its combustion.* The subjoined figures which represent the exterior view of it, the longitudinal section and the transverse section, will demonstrate clearly the principle of it.

The slab presents the external appearance of a parallelopiped, about 15 centimetres (6 inches) long, 3½ centimetres (2 1-6th inches) wide, and 25 millimetres (1 inch) thick; the materials which compose it are enveloped in a sheet of asbestos paper, only two thin sheets of brass being exposed to view, which serve as conductors of the current. The interior consists theoretrically of a prism of carbon and a prism of nitrate of potash, separated by a plate of asbestos, which plays very nearly the same part as the porous cell in ordinary batteries. In practice the sheet of carbon is formed of about 100 grammes of coal-dust, formed into a paste with molasses or tar. The paste thus obtained is strongly compressed, cold or preferably with heat, in a mould of suitable form, at the bottom of which has been placed previously a sheet of copper, of brass, or any other metal which is a good conductor, cut into several strips, which are found embedded in the agglomeration of the carbon and project from one of its extremities to constitute the negative pole. The mould is disposed in such a manner that the slab is perforated throughout its thickness with numerous holes intended to facilitate combustion and to multiply the points of contact of the carbon with the nitrate, as we shall presently see. It bears besides upon the upper surface rectangular depressions 15 millimetres deep divided by transversal partitions more or less numerous, obtained by the moulding. The angles thus formed are intended to prevent the flowing of the melted nitrate into the fire during the working of the apparatus. The whole surface of these compartments is covered by a thin sheet of asbestos paper. The upper part of the brick is formed of a mixture of three parts of ashes and one part of nitrate of soda or potash. The ashes are intended to prevent a too rapid combustion, and to prevent the slab from melting. This mixture is melted and poured upon the brick very hot and in a syrupy state. About 100 grammes per slab are required, equal to about 25 grammes of nitrate and 75 grammes of ashes. A second sheet of copper or brass analogous to the first is embedded in the nitrate before cooling, and forms the second pole of the slab. The whole is enveloped in a sheet of asbestos paper.

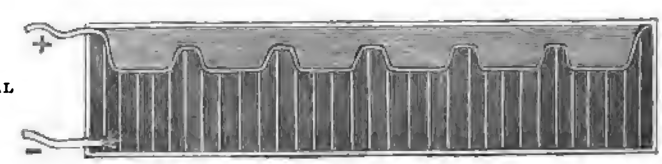
It is sufficient to place in a fierce fire the extremity of the slab opposite to the conductors, in order to obtain in a few minutes a continuous current—and a constant one if the slab is homogeneous—during its combustion, lasting an hour and a half to two hours. M. Brard has not yet taken the constants of this new thermo-chemical battery, but in an experiment which we owe to the chemical department of the laboratory of the Lycée of La Rochelle, a single slab was sufficient to actuate an electric bell of the ordinary commercial form.



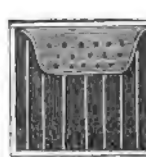
TOP VIEW.



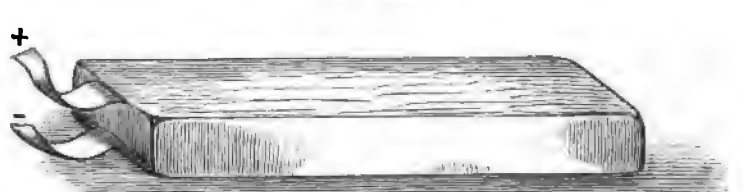
UNDERNEATH VIEW.



LONGITUDINAL SECTION.



TRANSVERSE SECTION.



GENERAL VIEW OF SLAB.

One can, moreover, burn several briquettes at once, and group them in tension or in quantity to increase the effect. Three or four slabs in tension produce the decomposition of water.

Such are the results at present obtained by M. Brard. Without expressing an opinion as to the future and the results which will be obtained from this apparatus, which is at present confined to the laboratory, we may observe that these researches are very interesting, and that to M. Brard must be ascribed the honour of having been the first to construct a veritable *electro-generative combustible*.

ELECTRO-CHEMICAL METHOD OF DETERMINATION OF EQUIPOTENTIAL LINES UPON PLANE SURFACES.

By M. Adrien Guébhard.

The remarkable works of the author are of a too theoretical nature, to our great regret, to allow us to submit them here to an analysis which would necessarily be succinct, and consequently incomplete. These works have, moreover, been published at various times in the *Comptes Rendus* of the Académie des Sciences, 1881-1882. We refer our readers to them.

The programme of the Physical Section included, besides the communications which we have just reviewed, certain others which were not read owing to the absence of the writers. The Physical Section having thus practically exhausted its programme separated, electing as President of the Section for the next year M. Bertin, subdirector of the Ecole Normale Supérieure, of Paris, and as delegates, MM. Alfred Niaudet and Edouard Hospitalier.

The La Rochelle meeting closed on August 31st. The twelfth session will be held one month, from August, 1883, at Rouen (Lower Seine).

Conferences.—During the Congress two public conferences have taken place, one on the deep water harbour of La Rochelle, by M. Bouquet de la Geye, the other on the electric light, by M. Hospitalier. This conference, without any scientific pretensions, held with the object of popularising the subject, presented one peculiarly interesting point: all the electric light experiments were made by the aid of thirty Faure accumulators, charged at Paris on Sunday, sent express to La Rochelle, and employed on Wednesday evening for the conference without having sensibly lost their charge. They were used to work arc lamps, a Jablochkoff candle, a Reynier lamp, and the incandescent lamps of Edison, Swan, and Maxim. After the conference they still contained sufficient electricity to operate a Mangin projector of 200 burners. The total energy stored up represented nearly one horse-power during eight hours.

CORRESPONDENCE.

TO CORRESPONDENTS.

No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer, not necessarily for publication, but as a guarantee of good faith.

Correspondence should arrive not later than Tuesday morning if it is desired to appear in the following number.

ECONOMICAL ELECTRIC LIGHTING ON A SMALL SCALE.

To the Editors of The Electrical Review.

Sirs,—In South Africa we are debarred from the many advantages enjoyed by young men in England for experimenting, and the amateur scientist of limited income here gets confused and sceptical when comparing the knowledge he attains by studying the various text-books by eminent men on electrical science with those applications of the science for really useful purposes.

Men who live wholly upon the plane of science describe their and others' discoveries and inventions in such a positive and eloquent style that begets faith in the minds of those dwelling upon the lower plane of commerce and practical application, who watch with hunger and patience for the crumbs, &c. But it so frequently happens that what is published from the master's plane as a valuable practical application of a law of force is, when viewed by those who have anxiously awaited its development, a mere toy, or a piece of mechanism too delicate for hands other than those of pure scientists. Thus the outsider is deluded by the pictures descriptive of important discoveries; for he finds that when brought down upon the plane of useful application the atmosphere is too dense and they cease to exist.

I trust you will accept this as a sufficient excuse for requesting information of a useful nature upon the subject of lighting by electricity on a small scale.

Dynamo-electric machines are by far too expensive, cumbersome, and unmanageable for use in private houses. Voltaic batteries, although much cheaper (that is, involving less outlay) and more manageable, are still very troublesome when compared with the use performed.

In this country paraffine oil is the chief source of artificial lighting. What is required to supersede that method *partially*, for purposes requiring a better light, is an easily manageable, and not costly, means of applying electricity; something which would effectually replace the bulk of a battery—reduce a battery to a few cells—would accomplish what is needed. There are many who would not object to a reasonable amount of trouble to secure the advantage of a superior light. Now, a good deal is said in text-books on electrical science about the great power of "current induction coils"—that the current from a few cells of a suitable battery produces powerful effects when passed through an induction coil of even small dimensions. Dr. Ferguson writes:—"Of late years coils of great power have been constructed, *rivalling, if not exceeding, the most powerful electric machines* in length and power of spark." Yet little or nothing is said at the present time about their application to electric lighting in households. Mr. J. W. Urquhart, C.E., in his work on the "Electric Light; its Production and Use, &c.," merely mentions that some generators have been constructed upon the principle of current induction, and says they are not the most successful, and passes the subject by. This would make induction coils, from a practical standpoint, appear of no value, in spite of the fact that every scientific writer on electricity speaks so very highly of them.

Your valuable journal seems to be the only source of thorough information on these matters—so highly desirable in the interests of this rapidly developing science as a guide to the sanguine uninitiated—and I shall be glad to know if it is economical to use induction coils in place of large batteries for the production of a light for everyday use. Is the light steady produced through this medium? If not, can a small secondary battery be used between the induction coils and the lamp with the effect of steadying the light? If so, whose make is the best for real use? Can more than one lamp be used in the circuit, either in series or multiple arc? Any information of a practical nature will be esteemed.

NATALIAN.

July 21st, 1882.

[We will endeavour to answer our correspondent's letter fully in our next issue.—Eds. Elec. Rev.]

RECENT PROGRESS IN TELEPHONY.

To the Editors of The Electrical Review.

Sirs,—On reading the paper, in last Electrical Review, as read by Mr. W. H. Preece, on "Recent Progress in Telephony," before the British Association, I was struck with the similarity of an experiment, and even the use of the very words, as was done and used by an old friend of mine thirty years ago. The words I refer to are put in italics in your report, and are "*to communicate across seas and channels without the aid of wires at all.*" This individual was a Mr. J. B. Lindsay, of Dundee, a man who was evidently born fifty years too soon; devoted a great portion of his time to electric lighting and telegraphy; demonstrated the practical possibility of sending needle deflections across large bodies of water, across the docks at Dundee in 1848, and 1850, across the Tay at Perth and the Dee at Aberdeen. In 1859, at the latter, city Mr. Lindsay endeavoured to demonstrate his system before the British Association then assembled there, but was barely listened to, and laughed at as a visionary.

With your permission I will be glad to give more about this uncommon man's many electrical ideas—ideas which have since become realities.

I am, &c.,

G. LOWDON,
Electrician.

Dundee, *September 4th*.

[We shall be glad to receive any further communication on these matters from Mr. Lowdon, if authentic.—Eds. Elec. Rev.]

THE TELEPHONE.

To the Editors of THE ELECTRICAL REVIEW.

SIRS,—I was not so far wrong, it seems, when I remarked that "Justice" had more of *law* than of justice in his composition: for what I suspected he now admits, namely, that his letter was based not on the real justice of the question, but upon a Chancery judge's decision—which may or may not be accepted as final, and which proves nothing on the abstract point, because it does not follow as a necessary truth either that the proper evidence was placed before the court, or that the court was able to appreciate questions of electrical science. As to the "blissful ignorance" of Sir Frederick Bramwell on matters electrical, I decline to enter upon such a personal topic. But as your correspondent, "Justice," cites the judgment of Mr. Justice Fry, I have consulted a copy of that document, and I find that the learned judge lays down with great clearness and discrimination that the class of tension-regulators which Edison's claim is held to cover (in combination with a diaphragm), is a class in which the tension-regulator is made of a substance that is compressible, semi-conductive, and resilient. The judge adds, "I think, therefore, that the true meaning of the claim which I have just read, is the union of a tympan or diaphragm capable of vibrating under the sound-waves with an electric tension-regulator *having the quality* which I have just described." (I italicise the words which "Justice" has overlooked.)

Further, I am compelled to differ absolutely from "Justice" on a point of the very gravest moment.

"Justice" says: "I now merely recite the words of the decision of Mr. Justice Fry, who did not think it had been established '*that Reis's transmitter combined a diaphragm with a tension-regulator.*'" I italicise the words which "Justice" says he "merely recites" from the decision, and which "Justice" puts into quotation marks. Now I have gone carefully through the twenty-seven pages of the printed judgment delivered by Mr. Justice Fry, with the remarkable result of finding that the words which "Justice" says he "merely recites," are not to be found therein at all from the first page to the last. Mr. Justice Fry in his decision does not use those words nor anything approaching them. On the contrary, he says (see printed Judgment, p. 11, line 32): "*Such a tension-regulator as Mr. Edison invented has been discovered in Reis's instrument.*" I, therefore, deliberately accuse "Justice" of a contemptible and disgraceful literary fraud in attempting to palm off as a quotation from Mr. Justice Fry's very clear decision, words which not only are contrary to the sense of that decision, but which are not even to be found there at all.

I must absolutely and peremptorily decline to say one word more in reply to a writer who can thus abuse the name of "Justice," in order to perpetrate so palpable and monstrous an INJUSTICE.

ELECTRIC LIGHTING CONTRACTS.

To the Editors of THE ELECTRICAL REVIEW.

DEAR SIRS,—I have much pleasure in replying to Mr. Hammond's letter. My object in writing you was merely to contradict a statement which, unless explained away, might have had a detrimental bearing on the Pilsen Company. Mr. Hammond's explanation is in every way satisfactory, and I regret that he should consider that any imputation was made by me, and assure him it was not intentional.

I remain, Yours faithfully,

JAMES BEATTIE.

6th September, 1882.

MANGANESE.

To the Editors of THE ELECTRICAL REVIEW.

DEAR SIRS,—Will you kindly, through the medium of your columns, give me some information about Manganese. We have several mines of it in this district lying idle. A trial shipment was sent to London (some 50 tons) a few months back, but no returns are yet to hand. I should like to know something of the different kinds that are at present in demand, and of the mode of reducing the ore. If I am asking for more information than you can afford to give in your columns, would you kindly let me know in what works I could obtain it. AN OLD SUBSCRIBER.

Port Curtis, Queensland, *8th July*.

[Owing to the pressure on our space we are this week obliged to leave over answers to correspondents. In the meantime perhaps some of our readers may have such information at hand as "An Old Subscriber" desires.—EDS. ELEC. REV.]

NOTES.

ELECTRICAL REVIEW.—REMOVAL OF OFFICES.—On and after this date the REVIEW will be published at 22, Paternoster Row, to which address letters for the "Editors" may be sent. Business communications to be addressed to H. Alabaster, to whom cheques and post-office orders (on chief office, London) should be made payable.

THE DOMINION TELEGRAPH AND SIGNAL SERVICE.—We make the following extract from the *Dominion Annual Register*, 1881:—"A telegraphic and signal service has been established at Ottawa as a regular branch of the Public Works Department, under the management of the well-known engineer and electrician, Mr. F. N. Gisborne, the original projector of the Atlantic cable. His appointment by the Government of Canada dates from 1st May, 1879."

The following is a brief summary of important services performed under Mr. Gisborne's management:—"The construction of the coast telegraph line between Canse and Halifax, Nova Scotia, under contract with the Dominion Telegraph Company; the inspection and reorganisation of the telegraph service in British Columbia, and subsequent purchase from the Western Union Telegraph Company of all their lines and cables within the province, whereby the saving of a large annual expenditure was effected; the fitting out, under contract with the India-rubber, Gutta-percha, and Telegraph Works Company, of London, England, of the Government steamer *Newfield* as a cable ship, and the subsequent laying of the following submarine electric cables: Anticosti Island to Gaspe, Province of Quebec; Magdalen Islands to Cape Breton, Nova Scotia; Bras d'Or, Lake Crossing; Grand Manan to Campo Bello, New Brunswick; and Campo Bello to Eastport, State of Maine; all of which are in successful and economical operation. The construction under contract with Messrs. Kennedy, Bertrand and Co., of the land lines upon Anticosti, and the Magdalens, in connection with the Hon. P. Fortin's comprehensive plan for establishing signalling stations and fishery bulletins throughout the Gulf of St. Lawrence and shores of the Dominion; the construction under contract with Messrs. Robinson and Co., of the land lines upon Grand Manan and Campo Bello Islands; the erection, under agreement with the Dominion Telegraph Company, of a land line between Bay St. Lawrence and Sydney, Cape Breton, Nova Scotia. The submergence, under Mr. Gisborne's supervision, of the following electric cables: Saanich Arm-Nanaimo to Gabriola, Vancouver Island; Valdes Island to Point Gray, British Columbia; also the raising and repair of six old cables upon the San Juan Island route; the construction (now in progress) under contract with the Montreal Telegraphy Company, of land lines between Baie St. Paul and Chicontimi, and Murray Bay, towards Point des Montes."

It will be seen from the above that Mr. Gisborne's services have been of a most valuable character, and are held in high appreciation, not only by the Government, but by the people and press of the country generally.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY'S CABLE SHIPS.—The *Panama Star and Herald* of the 10th ult. gives the following information as regards the movements of the repairing vessels of the West India and Panama Telegraph Company:—St. Thomas, August 4th.—The cable ship, *Duchess of Marlborough*, returned here yesterday from Grenada, having repaired the section between that island and Trinidad. The cable steamer, *Grappler*,

also returned to harbour for a supply of steel wire grappling rope, which was quickly transferred from the *Duchess*, and the latter having coaled, both steamers left early this morning to effect the repairs of the St. Thomas and St. Kitts section. The *Grappler* has already been occupied on this nearly five months, during which time she lost several thousand fathoms of valuable steel grappling rope, grapnels, and buoys. She is now working in over one and a half miles of water. This great depth, and the irregular and rocky nature of the bottom, are retarding operations. The weather lately has been rough, and has washed the buoys off the cable when, with calm weather, it would only have been a matter of a few hours to complete the work. This cable when repaired will be practically a new one. The whole of the line from St. Kitts to within about twenty miles of St. Thomas having been submerged during the last twelve months.

AUTOMATIC ELECTRIC SIGNALLING ON RAILWAYS.—An evening paper, prone to indiscreet dabbling in scientific matters, says that "a tolerably complete scheme of the kind was invented and patented several years ago by Sir David Salomons, and it has been re-invented and patented two or three times since." The fact is Sir D. Salomon's invention was not patented till October 13th, 1874 (No. 3,515), whilst a similar device had been invented and patented by Mr. W. T. Whiteman as early as January 22nd, 1874 (No. 270).

ELECTRIC RAILWAY IN SWITZERLAND.—From Switzerland it is reported that an arrangement has just been concluded by Mr. Pearson, of the London firm of John Taylor and Co., on behalf of a syndicate of English capitalists, and Mr. Theodore Turrettini, acting for the local government, for the construction, on the Edison system, of an electric railway from St. Julien, in Savoy, to Ferney, and thence to Geneva. The total length of the line will be about 16 miles.

THE GERMAN RAILWAY ACCIDENT.—The telegrams from the continent agree that the appalling railway accident which happened near Hugstettin on Sunday last, when upwards of fifty persons were killed and numbers injured, was caused by a telegraph pole having been thrown across the line during a thunderstorm. As we may shortly expect stormy weather, it is, perhaps, not too much to ask the railway companies to cause their lines to be carefully examined, so that a similar catastrophe in our own country may not be chronicled.

THE TELEGRAPH ARRANGEMENTS OF THE ARMY.—The telegraph arrangements of the army in Egypt are ordered to be under the commanding officer of the Royal Engineers, and to be divided into two portions—that in front of the advanced depôt, and that between the advanced depôt and the base of operations. Arrangements have been made for detachments of soldiers to patrol all the telegraph lines to prevent the wires being cut or tapped by the enemy, and for military guards to protect the telegraph stations. Stores have been sent out for 12 stations. In addition to the necessary telegraph waggons and reels, there have been sent 24 "sounder" instruments for the dozen stations, and 15 Morse recording instruments for field work, together with 360 rolls of Morse paper, 48 Leclanché 10-cell batteries, 500 insulators, 200 iron telescopic telegraph poles, a large number of wood poles, 12 lightning protectors, 12 wheels for cipher signalling, 1,200 yards of copper wire covered with gutta-percha, 36 miles of insulated copper wire, and 36 miles of insulated galvanised iron wire. In addition to the above, the Royal Engineers have taken out an assortment of stores for army signalling, *i.e.*, effecting communication by means of visual signals between different posts in forts and military stations. Among these are 36 hand-draw telescopes for field observations, 72 gas-bags, and 36 pressure-bags for the lime light for night signalling, 36 lime light lamps, 72 large powerful bull's-eye signalling lamps, 36 heliographs, 36 fog-horns, and 72 army signalling flags and poles. Altogether, the telegraphic and signalling arrangements of the campaign are said to be the most of those of any army which ever took the field.

TELEPHONING EXTRAORDINARY.—According to the Bradford *Daily Chronicle*, a well-known reciter gave "As you like it," the other evening, in the Technical School. The Telephone Company, which has subscribers in Halifax, Leeds, Dewsbury, and Huddersfield, supplied them with a treat, for there were placed on a table on the platform several different kinds of transmitters, thus enabling all their subscribers, who were miles away, to hear the recitation. The subscribers at Leeds, during the evening, notified that in addition to hearing the elocutionist, at the finish of each act the applause of the audience was quite audible. Each evening, when a performance takes place in the hall, it is to be heard at the various towns where subscribers reside. At one of the chapels in Halifax the telephone is fixed to the head office at Bradford, and it is said that each Sunday the service is heard in Bradford.

THE TELEPHONE CABLE ACROSS THE TAY.—On Monday the Dundee Harbour Trustees considered the application of Mr. Young, District Engineer of the National Telephone Company, Limited, for permission to lay a telephone cable near to the Post-office cables at West Ferry, for the purpose of connecting Dundee to Fifeshire. The meeting resolved that the Harbour Trustees, in so far as they are interested, assent to the laying of the cable by the aforesaid company at the place referred to, on the company obtaining the consent of the Board of Trade to the proposed operation.

THE FRENCH ATLANTIC CABLE.—We observe that the steamer *Scotia*, Captain Cato, belonging to the Telegraph Construction and Maintenance Department, left Plymouth on Saturday, to renew her efforts at repairing the French Atlantic cable. This, after being repaired a thousand miles from Plymouth, again parted within 20 miles of the original breakage. The *Scotia* has taken coal and provisions for two months.

QUICK RETURNS.—The Eastern Telegraph Company are said to be realising by the war in Egypt a daily revenue of £6,000. This income is derived exclusively from the despatches—official and press—sent from the headquarters of the army on the Canal and from Alexandria. Until the outbreak of the war there was no direct telegraphic communication between Port Said and Alexandria. The Eastern Company laid a cable from Alexandria to Port Said, at a cost of £24,000 and this sum was paid off by the revenue of four days.

ELECTRIC LIGHTING AT EASTBOURNE.—The Local Board of Eastbourne having entered into a contract for the lighting of the principal thoroughfares by electricity, on Friday the 1st inst. the Parade was illuminated by 16 Brush lights. Other lamps are soon to be in operation, the dynamo-electric machine employed being capable of producing 40 lights. Of the present installation the last lamp is at a distance of two miles from the station, and a length of cable amounting to four and a half miles is used, laid underground.

ELECTRIC LIGHTING.—At a meeting of the Aberdeen Town Council, held on Monday last, the Gas and Lighting Committee reported that, having considered the remit made to them with reference to the bill promoted by the Corporation in relation to the supply of light by electricity, they were of opinion that no action under the statute should be taken at present. This recommendation was adopted. The Lord Provost said their gas engineer might be instructed to make some experiments in electric lighting which would be productive of considerable interest to the city. He hoped the committee, in making up the gas estimates for the year, might be able to consider whether they would not set aside £200 or £300 in order that the engineer might have an opportunity at some suitable place to make experiments on behalf of the city.

A letter from the managing director of the Brush Electric Light and Power Generator Company, asking the Edinburgh Town Council to make a trial of their light on Waverley Bridge and North Bridge, engaged the attention of the Cleaning and Lighting Committee on Monday. While there is an evident chariness to further experiment with the electric light, the fact that while Princes Street is fairly well

lighted by Bray's gas burners, it is at a cost greater than the electric light; that the terms now proposed are more favourable than those concluded last year, and that the North British Railway Company, instead of giving it up, are extending its use, will not be without their influence on the decision of the sub-committee, to whom the question has been entrusted.

THE ELECTRIC LIGHT IN ST. LUKE'S.—The *City Press* says that the vestry of St. Luke's, Old Street, has received a letter from the Metropolitan (Brush) Electric Light and Power Company (Limited) asking the consent of the vestry to the grant by the Board of Trade of a licence, under the Electric Lighting Act of last session, for the supply of electricity within the parish, to be taken into consideration at the next meeting of the vestry.

ELECTRICAL ENGINEERING.—The Hammond Company Electrical Engineering College at 2, Red Lion Square, was opened last Wednesday for its first session, after an introductory speech by Mr. Robert Hammond. We hear that the College starts with 25 pupils. Mr. H. E. Harrison, B.Sc., is the Principal.

THE RESISTANCE OF CARBON.—In the course of his paper on "Recent Progress in Telephony," read before the British Association meeting at Southampton, Mr. Preece remarks, when speaking of carbon: "It has the remarkable property of having its resistance lowered when it is heated—the reverse of metals. This observation is due to Mr. Shelford Bidwell." It is rather to be regretted that Mr. Preece did not give the date of Mr. Bidwell's discovery, more especially as Mr. S. A. Varley had entered very fully into this matter in a paper, also read before the British Association, in 1870.

ELECTRICAL APPARATUS.—We have received an illustrated descriptive price-list of apparatus manufactured and supplied by Messrs. H. and E. J. Dale, of Little Britain, London, E.C. The catalogue commences with frictional electricity, and a very complete list of machines and experimental apparatus in connection therewith is given. Magnets and electro-magnets stand next in order, followed by resistance coils, and an exhaustive selection of galvanic batteries and chemicals, some of the more important being of Dale's special construction. The patent "granule" battery is said to give exceedingly good results, four of the large cells keeping a Swan lamp of 5 candle-power in action for forty hours. Telegraphic apparatus, induction coils, telephonic and electric lighting apparatus of all descriptions, together with almost everything appertaining to electrical matters. In fact the catalogue is one of the most complete we have had occasion to peruse, and we can strongly recommend it to all desirous of purchasing electrical apparatus.

ELECTRICITY IN FRENCH LIGHTHOUSES.—A recent law of the French Legislature authorised the application of the electric light in no fewer than 42 important lighthouses on the coasts of France. The total expense of this change is estimated at about £320,000 sterling.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—At 10 o'clock on the morning of the 23rd August, the William Molson Hall, Montreal, was crowded by a brilliant and distinguished audience, to welcome the American Association for the Advancement of Science.

This the 31st annual meeting of the association is one of the most successful yet held; the list of applicants for membership being large, and the papers in the hands of the committee numbering upwards of two hundred. The retiring President, Professor George J. Brush, of New Haven, Connecticut, introduced the new President, Principal J. W. Dawson, F.R.S., F.G.S., &c., who thanked the association for the honour conferred, and said, "I accept it as the choice was in some degree determined by the wish to do honour to Canada, and to give to the meeting a character as thoroughly international as possible. Science from her serene height overlooks all the national boundaries and comprehends the whole world in her scope of vision. It becomes us, therefore, for the time being to merge the character of citizens of the United States of Canada in that of cosmopolitan men of science."

The President stated that the annual meeting of the British Scientific Association opened that day in Southampton, England, and he suggested that a message of greeting be cabled to it from this association, a proposition which met the approval of the meeting.

Dr. T. Sterry Hunt next addressed the association, and after several speeches of a complimentary character, the association divided into nine sections. Section B., Physics, is the only one that calls for notice in these pages. In this section Mr. W. Le Conte Stevens, of New York, read a paper on "Vision by the Light of the Electric Spark."

VISION BY MOMENTARY ILLUMINATION.

This paper was supplemetary to other papers published during the last year, in one of which Mr. Stevens had explained a new method of stereoscopy from a pair of perfectly similar pictures, by so adjusting these in position that the retinal images of them should be dissimilar, and thus the effect of depth in space obtained from the combination. He had explained these geometrically on the assumption that free motion of the eyes was possible in viewing them. The present experiments were conducted to ascertain whether the same effects could be secured when the period of illumination was so brief that no motion of the eyes was possible. Mr. Stevens explained the apparatus employed, which consisted of a reflecting stereoscope, arranged in such manner as enabled the observer to rotate the cards on a vertical axis, and at the same time to secure any desired relation between the visual lines. The electric spark was obtained from a large induction coil, and it was found that in nearly every case binocular effects were perceptible by the light of a single spark. The experiments were varied in many ways and quantitive results were obtained, to which Mr. Stevens referred. He called attention also to a peculiar stereograph, devised some years ago by Prof. Hines, of Pennsylvania, which viewed by momentary illumination showed that binocular effects are obtainable without the eyes of the observer being in such a condition as to make the perception of double images possible in any part of the binocular field of view. These experiments were performed not only with parallel vision, but also with strong convergence of visual lines, and the disturbance of judgment, due to unusual muscular conditions, was strongly brought out in this way.

AERIAL NAVIGATION PRACTICABLE.

Mr. Joseph L'Etoile, of the Department of the Interior, Ottawa, read his paper on "A Review of the Subject of Atmospheric Current, Electricity, and Gases, with a view to Practical Aerial Navigation by means of Balloons." The paper was illustrated with a proposed balloon of fish-like form with a screw at one end and a rudder at the other end. He said that the system of practical ballooning means that a balloon should ascend without loss of ballast and should descend without waste of gas. The balloon of the future should be given the shape of a fish provided with a propeller, a rudder, with gas and air pumps, and three gasometers, one for gas, one for air, and one for working the change of temperature in the balloon caused by the solar warmth, or moist in the air, so that by these means the balloonist or aeronaut can control his air vessel as easily as the engineer in his steamboat or locomotive. It is well known that when a balloon shoots up, the gas dilates, the gasometers or gauges tell the changes, and the balloonist adjusts to circumstances. A balloon built on this new plan can ascend or descend slowly, thus giving time to moteorological instruments to mark accurate changes. Charts could be made, and balloonists would know the routes of travel in the air, day and night, at any season of the year. To give an idea of the possibility of establishing those charts, the following may be *apropos*. For instance, a balloon sailing from America to Europe should keep within the lower region, when sailing from Europe to America it should sail in the high region. Why so? The reason is that cold air is heavier than warm air, consequently the cold Arctic currents prevail in high altitudes especially in northern Europe and America.

NEW COMPANY REGISTERED.

SOUTH STAFFORDSHIRE ELECTRIC LIGHTING COMPANY, LIMITED.—Capital £100,000, in £5 shares. Offices, 33, Waterloo Street, Birmingham. Objects: To produce and supply electric light, heat, and power, and also to carry on telegraphic and telephonic business. Signatories (with one share each): R. Williams, Wednesbury; T. Underhill, M.D., Darlaston; J. Smith, Wednesbury; E. Horton, Darlaston; J. C. Tildersley, Willenhall; J. Harper, Bilston; E. H. Carter and E. Pritchard, C.E., Birmingham; J. Solly, Tipton; J. Davy, West Bromwich; E. Howe, Tipton; L. Parker, Birmingham; P. D. Bennett, Edgbaston; Joseph Smith, Wednesbury; J. Slater, Darlaston. The signatories are to appoint the first directors. Qualification: £250 in shares or stock; the shareholders in general meeting will decide the remuneration of the directors. Registered August 31st, by Walter Webb and Co., 23, Queen Victoria Street.

NEW PATENTS—1882.

4158. "Apparatus for measuring and registering electric currents." A. L. LINEFF. Dated August 31.

4159. "Telephonic apparatus." J. H. JOHNSON. (Communicated by A. D'Arsonval.) Dated August 31.

4160. "Telephonic instruments." J. D. HUSBANDS. Dated August 31.

4162. "Electric lighting and apparatus, and fittings to be used therefor." T. T. SMITH. Dated August 31.

4168. "A new or improved carbon for use in arc or incandescent electric lamps, also applicable as the porous plates of secondary or polarisation, or other batteries or instruments, and for other analogous purposes." H. J. MARSHALL. Dated September 1.

4178. "Secondary or storage batteries." D. G. FITZGERALD and T. J. JONES. Dated September 1.

4180. "Manufacture of carbons for incandescent electric lamps." J. JAMESON. Dated September 1.

4186. "Voltaic batteries." L. HARTMANN. Dated September 2.

4192. "Electro-hydraulic meter for the measurement of electric currents." R. HAMMOND and L. GOLDENBERG. Dated September 2.

4198. "Galvanic batteries." E. B. BURR and W. T. SCOTT. Dated September 2.

4212. "Production and treatment of carbonised material to be used for filtration, and in the construction of electrical batteries, and for other purposes. J. H. JOHNSON. (Communicated by A. Caron.) Dated September 5.

4220. "Improvements in the electrical regulation of steam and other power engines and pumps, and in apparatus to be used therefor." A. W. L. REDDIE. (Communicated by A. Krásza and J. Schaschl.) Dated September 5.

4235. "A more simple and effective mounting, or holder, for filaments in electric incandescent lamps." L. R. BISHOP. Dated September 6.

4238. "Manufacture of incandescent lamps and apparatus therefor." W. CROOKES. Dated September 6.

4246. "Electric signalling apparatus, chiefly designed for telephonic purposes." W. R. LAKE. (Communicated by J. H. Cary.) Dated September 6.

4248. "Galvanic batteries." G. C. V. HOLMES and S. H. EMMENS. Dated September 6.

4250. "Dynamo-magnetic electric machines and magnets to be used in such machines, and for other purposes." T. DONNITHORNE. Dated September 6.

4251. "Obtaining and utilising electric currents." T. SLATER. Dated September 6.

ABSTRACTS OF PUBLISHED SPECIFICATIONS. 1881.

5578. "Transmission of motive power." W. G. S. MOCKFORD. Dated December 20. 2d. For this purpose, in place of using an endless cord or rope working over V grooved pulleys on the two shafts, or a band working over band pulleys, as heretofore usual, the inventor employs an endless cord or wire, or rope or chain, twisted with one or more twists or turns around a pulley or wheel on each of the shafts. In this way the cord, wire, chain or rope will have a great hold upon the pulleys, so that even when extremely slack there will be no slip of the cord, wire, chain or rope over them. In many cases it is sufficient to use a plain piece of wire, but in other cases wire rope would be preferable. (*Provisional protection not allowed.*)

5632. "Construction of incandescent lamps." J. S. SELLON. Dated December 23. 2d. This invention relates to the employment as a substitute for transparent glass as now ordinarily employed in the construction of incandescent lamps of such glass as is known as opal, that is to say, a semi-opaque or non-transparent glass. In carrying out the invention, the inventor either constructs the glass or bulb of the lamp of glass which has been rendered opalescent through its entirety or which has been rendered partially opalescent either by means of an internal or external lining, enamel coating, or application of an opalescent material. It will be understood that the bowl bulb or glass to be employed in the construction of incandescent lamps may be rendered either wholly or in part opalescent, that is to say, that either the inferior, the middle, the lateral, or the superior portion or the whole of the bowl bulb or glass may be coated or rendered opalescent. (*Provisional protection not allowed.*)

1882.

198. "Electric block signals, &c." J. RADCLIFFE. Dated January 13. 6d. The electric locking apparatus for levers is designed with the view to prevent the signalman of a railway from [illegible] his signal or shifting his points until he has received the signal "line clear" from the station or signal box in advance. In the improvements the inventor insures the locking of the signal lever by means of a vertical or nearly vertical bolt or bar, suspended from its upper end over a projecting tongue or shoe attached to and forming part of the clip-lock of the lever. A link attached to the armature of an electro-magnet is connected with the bolt or bar. The electro-magnet is connected by the conducting wire with the block-signalling telegraph instrument at the station or signal-box in advance, and in such a manner that an electric current is only passed to the electro-magnet when the block-signalling instrument is at "line clear."

297. "Galvanic batteries, &c." J. HIGGIN and A. J. HIGGIN. Dated January 20. 6d. Has for its principal object to lessen the cost of the production of galvanic currents by means of batteries and to this end elements and materials are employed which will furnish useful and valuable chemical products. In the description of battery which is considered to be most suitable to the purpose tin is employed for one element and carbon for the other, and dilute sulphuric acid for the exciting medium. In one form of a battery cell there is used a receptacle such as a stoneware jar in which is a hollow cylinder of tin with an inner porous cell containing a carbon rod or plate, which is surrounded with granular pyrolusite or manganese peroxide, which is used to absorb developed hydrogen. During the action of such a battery the action of the dilute sulphuric acid produces proto-sulphates of tin and of manganese which remain in solution. When it is desirable to renew the exciting liquid the solution obtained from the battery is treated in order to obtain such preparations of tin as are required in the dyeing and printing of textile fabrics and in other industrial processes. It is preferred to heat the solution with an added quantity of oxide of manganese, whereby the proto-sulphate of tin is converted into a per-sulphate. It is then only necessary to dilute the resultant with water in order to precipitate stannic acid or oxide from which other preparations of tin may be obtained by the employment of suitable or ordinary processes.

300. "Fire-extinguishing and alarm apparatus for use in theatres, &c." W. R. LAKE. (A communication from abroad by H. S. Maxim, of Brooklyn, New York.) Dated January 20. 8d. Has for its object to provide improved apparatus for automatically giving an alarm in case of fire and for extinguishing the same, the said apparatus operating by electricity and being caused to work by the action of the fire upon certain appliances suitably arranged.

339. "Regulating electric lamps." ERNEST DE PASS. (A communication from abroad by Bruno Abdank, commonly called Abakanowicz, of Paris.) Dated January 23. 6d. Has for its object to regulate electric lamps, by means of novel apparatus, or resistance balances, and which may be placed at any convenient distance from the lamps.

359. "Electric lamps." J. N. ARONSON. Dated January 24. 8d. Has for its object improvements in lamps in which several incandescing bridges or filaments are combined in one translucent globe or containing vessel, in which several globes or vessels, each with a single bridge or filament or are combined in one cluster, and in means or apparatus for bringing the said bridges or filaments of the lamp or of the clusters of lamps successively in the electric circuit automatically or by hand.

361. "Electrical conductors, or cables." W. R. LAKE. (A communication from abroad by H. A. Clark, of Boston, America.) Dated January 24. 6d. One object of this invention is to prevent the inductive action between the different conductors of a series lying adjacent one to another. Another object is, in electric cables composed of a series of wires, each and all surrounded and coated, and thus insulated with india-rubber, or gutta-percha, or restored waste, vulcanised india-rubber, or gutta-percha in any of their vulcanisable compounds, or with any other gum, or gums capable of vulcanisation, and suitable for insulation, to insure and maintain the proper separation and position for insulation of the several wires making up an electric cable, as to each other, during the process of vulcanisation. To secure the first-named object the inventor places a conductive body of considerable size, relatively to the size of the wires, close to the insulating coating of a series of insulated conductors, laid side by side, so that the electric impulses in any one of the said lines will expend their energy on the said conducting body rather than on the other lines of the series. To secure the second object of this invention the inventor places such cables in an oven, to be vulcanised, in moulds of a shape to maintain them in a practically straight condition from end to end of such moulds, and then vulcanises them in the ordinary manner, whereby the proper and relative positions for insulation of the wires on the cables are maintained, and the mould, containing a portion of a cable, being vulcanised as above stated, is made to project from the vulcanising oven, or chamber at the opposite ends thereof.

378. "Signalling apparatus for railways." W. P. THOMSON. (A communication from abroad by W. W. Gary, of Boston, America.) Dated January 25. 4d. The object of this invention is to provide a simple, reliable, and inexpensive single mechanism for use at crossings, curves, stations, and all other places at which audible or audible and visual warning is to be given when trains are approaching. (*Provisional only.*)

386. "Cores for telegraph cables, &c." W. T. HENLEY. Dated January 26. 6d. Refers firstly to the construction of a core with multiple conductors which may be used at will for a number of circuits, or for a few, or as one only, so that in an Atlantic cable, for example, for one part of the day or night it might be used as several telephone circuits, and the rest of the day or night as an ordinary telegraph cable of one circuit. This is done by a switch which, when turned in one direction, connects all the conductors in one circuit, and in the other direction connected in separate circuits from two upwards;

there must be a switch at each end of the line and at a given signal the switches must be set. The conductors are first insulated separately and then all closed in another coat of insulation, and then served with yarn and protected with wires in any well-known way; but in the improvement the core is surrounded with strong manilla or Russian hemp or strong fibrous material, laid up in closely spun yarns, which are laid round the core in long spirals and then served with galvanised steel wires of a small size, so as to combine lightness with strength; the cable is then covered with tape or yarn and compound in the ordinary way.

DISCLAIMER.

The Edison Electric Light Company's Disclaimer and Memorandum of Alteration. (Edison's Patent.) "Electric Machines and Motors." No. 1385. 1880.

CITY NOTES.

OLD BROAD STREET.

DEVON AND CORNWALL (BRUSH) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

ON Wednesday the statutory meeting of the shareholders of the above company was held at Cannon Street Hotel, under the presidency of Mr. W. H. Owen.

The notice convening the meeting having been read by the secretary, Mr. F. B. Lidstone,

The Chairman said: Gentlemen, this is what may be termed a statutory meeting. It is the meeting which is usually held in accordance with the statute regulating joint-stock companies' proceedings. It is provided that the first general meeting should be held within four months from the formation of the company. Usually there is nothing to say at such a meeting, further than to give such information as the shareholders may desire to have, and that I shall proceed to give you as shortly as possible. The first thing I may say is that I rather regret there are not more shareholders present than I have now the satisfaction of seeing. In one sense the directors may take that as a compliment to themselves, for if any large number of shareholders had been dissatisfied with the position and affairs of the company there would have been more here to make complaint of it. The directors are glad to have the opportunity of giving you an account of their very brief stewardship, and you will probably not expect to hear that much business has been done. The very nature of the thing we have to offer to the public is not such as to admit of its instantly being shown for a purchase to be made instantly. The introduction of the electric light must be carried on very cautiously, carefully, and quietly. It is a thing, as we say in common talk, of which the thin edge of the wedge has to be got in and then it may be driven home. There is a strong interest opposing the electric light —namely, the gas interest. The people to whom the electric light is offered like generally to drive a bargain for themselves. They say, "Oh, yes, we shall be very glad to have the light, but you must let us have it at the same price as we get gas." But we reply, "You cannot have a better article at the same price." This is the way we have been met, and we shall be met in future. Still there is a prospect of doing something, particularly in Plymouth, which is a very enterprising place. Plymouth has received the offer of the light very cordially indeed. The directors are now negotiating for installing the light there. I hope you will approve the course the directors have been pursuing. They have not been anxious to jump at anything or accept always the terms offered. If they went into matters in an improvident way they would spend your money to no profit. There has been a little commencement made. There was a very extensive fancy fair in the city of Exeter recently, and the light was shown there. The hall was lighted up, and it was well done, and payment was made to the company for three days. There was a further day upon which the light was used, and which was agreed to be paid for, but has not been yet; and there was a fifth day on which the light was used, and it may be a matter of transfer. We have had the use of a cellar in the hall for storage purposes, and one will be a set-off against the other for rent. The directors are of course anxious to make money by the exhibition of the light at Plymouth to some persons desirous of having it. There would be in addition to making money an opportunity of advertising ourselves, and advertising our light; and when the light is exhibited in a business place like Plymouth, I think it is more than probable, almost certain, that the people in Plymouth will, after having seen the light, take more kindly to it than they are at present disposed to do. There are, moreover, prospects in the dockyards. At Portsmouth they use the electric light upon the Brush system. I was told, on applying to the authorities at Devonport dock, that they are now about transferring some light from Portsmouth, where it is not wanted, to Devonport dockyard, where electric light is wanted. So that there is some prospect of doing business there. I may say this, that I am rather sorry one or two shareholders have expressed some dissatisfaction at the directors not having done any business. Business can be done to any amount almost if you pay out money, but we look for a return. There is another undertaking at Penzance. There are the head-quarters of the mining industry of Cornwall. There is a very large field in the Cornish mines for the introduction of the light. Although we are not working in the colliery district, still I take it that mines are on the same footing. The electric light would be of immense service and of immense utility in the mines of Cornwall. Penzance being the headquarters, there is a good reason why we should make an exhibition upon the undertaking of Penzance paying for it. It would be a very good advertisement to us in a very large district without any expense to ourselves. I shall be happy to give any further information that any shareholder may desire if any shareholder has any question to ask.

Mr. J. S. Tyler asked whether and why the directors issued the prospectus stating that the directors had the exclusive right to use or sell in Devon and Cornwall the Lane-Fox incandescent lamp? He found on searching the patent register that on the 27th July, 1881, Mr. Lane-Fox granted a general licence to the British Electric Light Company for the use and sale of his lamp, and it seemed from the register that that licence was granted in consequence of the agreement which Mr. Lane-Fox had previously entered into with the British Electric Light Company, and in consequence of proceedings the British Electric Light Company took against Mr. Fox in Chancery. He found no revocation of that licence whatever. Even if it were revoked it had not been recorded, and that was a serious matter for this company. He should like to ask if the licence to the British Electric Light Company had been revoked; what was the position of the company in respect of the rights of the liquidator, if there should be one, of the British Electric Light Company, or the trustee in bankruptcy, if there should be one of the Lane-Fox? Then, if the answer was that the licence was revoked, he should ask how and when it was revoked, and why the directors, through their solicitors, did not take care that such revocation was registered. He further wished to know what was the exact terms of the parent Brush Company and whether any contracts had been signed or entered into by the directors since his interview with them yesterday? Perhaps he might be allowed to inform the meeting that he had not put these questions to the chairman off-hand, but that he called on the secretary yesterday and told him, as he got no satisfactory answer then, that he should put them at the meeting.

The Chairman said the questions might be formally put into one.

Mr. Tyler said he should like further to ask why the directors did not through their solicitor take care that the revocation, if such was the case, was registered. He omitted to say that the Anglo-American (parent) Brush Company do not now grant the licences they used to do. Formerly they granted licences for the exclusive right to use the Lane-Fox; now they give one for the use only.

The Chairman: Can you give us the date?

Mr. Tyler: About three months ago; after the Metropolitan.

The Chairman said that alteration was made subsequent to the formation of this company from circumstances which came to the knowledge of certain persons. The question resolved itself into this —Was it not a fact that such and such a transfer had been made—he was using his own words—whether, in fact, they had the exclusive legal right to the use of the lamp, or whether they had not? His answer was that unless the directors really supposed that they had such exclusive right they would not have issued such a statement. The company did not know of anything to the effect that they had not the exclusive right. If a fraud had been committed upon them by the sellers they had their remedy. Nothing had been signed or done since yesterday afternoon. The Anglo-American company saw the prospectus before it was issued, and if they saw anything they disapproved he took it that they would have had the honesty to say, "Well, you are preparing to use something we have not sold you."

Mr. Shippey failed to see what was the immediate hurry for winding-up the company. He was a small shareholder, and he could bring to the use of the company a lamp for mines which would return 50 per cent. for their money. It was absurd to propose the winding-up of the company when electric lighting was only yet in its infancy.

The Chairman said he thought the remark was a little beside the mark; he had heard no direct hint about winding-up the company.

Mr. Tyler said he thought the answers given extremely unsatisfactory. Was it a fact, or was it not a fact, he wanted to know, that on the 27th July, 1881, Mr. Lane-Fox granted a licence to the British Electric Light Company for the exclusive use and sale? He had carefully taken the numbers of the patents from the register, and they corresponded with the numbers in the company's book, and it was quite clear that the licence dealt with by the British Electric Light Company was that identical patent this company had the right to sell and use in Cornwall. He could not conceive why the directors wanted to go into a groove which was opposed to that of the shareholders. Some inquiries should be made. Renshaw's were very accessible. Why was not information sent for from them, asking if it was a fact that the licence was revoked? The information could be got in a minute. There had been time that morning to make inquiry. The whole thing was in a nutshell. Although he was only a young man he had had some experience.

The Solicitor: In winding-up?

Mr. Tyler: No; not in winding-up companies (laughter).

Mr. Tyler said they were dealing with promoters' nominees, practically. And in these days, when promoters' nominees were qualified by promoters' money, he thought it behoved every shareholder in a company like that to be very careful what he was about, and in view of what had been discovered on the register concerning this company, he thought they ought to appoint a small committee of independent shareholders—not officers of the company—to investigate this matter of the licence between the British Electric Light Company and the Anglo-American. If a shareholder had come to him, as a director, he should have treated him courteously; but he was not received courteously. Not an inquiry had been made, although the solicitors were on the spot with the information in their pockets. If the board considered that satisfactory he must submit that he did not. He was only the holder of twenty-five shares, but he did not like losing his money. He was of opinion that there existed that licence he spoke of, and that there existed, in consequence, the necessity for this investigation. If the prospectus was wrong there must be a question of the personal responsibility of the directors, at any rate of their solicitors. What they ought to have done was to have searched the

register. One gentleman at the meeting yesterday said that the Anglo-American had a million of money at its back. He believed it was public knowledge that that company had parted with nearly all the money they had got, and that, taking all the money they were entitled to, and taking the shares as money, the sum does not reach half a million. He was perfectly satisfied in his mind that if the licence with the British Electric Light Company still existed, the Anglo-American, to save themselves, must come down with the damage or there would be a serious question whether the directors were responsible to the shareholders. He moved that a small committee be appointed, as he had suggested.

The Chairman said the previous speaker needed to be very careful how he dared to make such statements as he had, involving a clear untruth. That gentleman said that the directors were promoters' nominees.

Mr. Tyler: No. I said in these days when directors are promoters' nominees.

The Chairman: The gentleman appears to me to desire to disclaim what——.

Mr. Tyler: No.

Mr. Maudsley: May I beg you to sit down? I am a shareholder in the Anglo-American, and a director in the Great Western, and I hold 1,000 shares in this company, and I have paid every farthing, as every director has.

Mr. Tyler: You treated me very civilly, and were the only one.

Mr. Maudsley continuing said that this company hoped one day, not only from the effect of electricity itself, but also by the combinations which some of them had in connection with these county companies, that they would be able to establish many which would be for the benefit both of sellers and consumers. He thought that the statement concerning the legal points raised between the two companies he (Mr. Tyler) had named, had nothing to do with this meeting at the present time. This company had not only the influence but the consideration of men in different companies who are working for the general good, who were trying to carry out the system which it is intended to develop. Scientific minds are at work, some of them having patents are hoping to improve upon the machinery, by which the money invested in these companies will be lowered in primary cost, and that it may become useful to all and to every one who may be ready to use it.

The Chairman said the statement that the board were the nominees of promoters could not be tolerated for a moment. He was about to say, when interrupted, that it having appeared that what Mr. Tyler said, or intended to say, had been misunderstood. It seemed to him that Mr. Tyler disclaimed that which he is supposed to have said. He wished to say that in Mr. Tyler making allusion to the board of directors of this company there was a distinct insinuation that the directors were the nominees of promoters. Not one director has received any qualifying assistance, aid, or help in any way. He thought one director having 1,000 shares was a sufficient guarantee that Mr. Maudsley meant what was right towards that company, and would not tolerate one director associated with him being the nominee of a promoter.

Mr. Tyler: But what about the licence?

The Solicitor (to Mr. Tyler): If you will come to my office I will show you the licence. The onus is now upon you. You make a statement that we have no right to the Lane-Fox. The title is perfectly good; there is not the slightest ground for your surmises.

The Chairman said Mr. Tyler had made many curious inquiries except the right inquiry, keeping aside all possibility of removing any doubt. He had established those doubts in his mind, and he had cast them out broadcast. He said, in fact, "I told you yesterday that those doubts existed; why have you not made inquiries?" He said, in fact, "Do you know what you have is worth nothing?" Well, the board did not know that to be the case, but said they would talk it out at the meeting to-day. But why did not Mr. Tyler pass a little more time in going to the solicitor whom he named? saying, "I dare say you can give me this bit of information. I am a shareholder in the Devon and Cornwall."

Mr. Tyler: They would not give me an answer.

The Chairman: Be quiet, sir. You must not interrupt me.

Mr. Maudsley: Do sit down, please, sir.

Mr. Tyler: I will sit down for any other shareholder, but I shall not for you. They would not give me an answer.

The Chairman: You must not interrupt me ("Chair, chair"). Why did you not give us time to make the inquiry? This gentleman came to the office late yesterday afternoon, when all offices were about closing, so that we had not fair time to make the inquiry.

Mr. Russell Evans (a director) said Mr. Tyler's remarks at first did not strike him as pointing to the winding-up of the company; but he could see now that whatever his views might be with regard to the licence, it was the winding-up of the company to which the tendency of his remarks pointed. He was always under the impression that when people had a large sum of money behind them they were a good mark to shoot at, if they sold what did not belong to them. The Anglo-American had a large sum of money not called up upon their shares. He thought the shareholders of the Devon and Cornwall had excellent clients to shoot at if they had not got a good thing. Mr. Tyler had no right to say that Mr. Lane-Fox was a poor man. He (Mr. Evans) felt as satisfied about everything connected with this company as he was of the licence; he should be assured that everything was perfectly safe.

The Chairman said Mr. Tyler's statement was not in order at that meeting. The seventy-seventh clause of their articles of association said that "it is provided that any member entitled to be present and vote at a meeting may submit any resolution to a general meeting provided that at least the prescribed time before the meeting he shall have served upon the company notice of motion," which Mr. Tyler had not done. The directors wished to take the shareholders into their confidence, and to keep nothing back.

Mr. Phillipson: I will second Mr. Tyler's motion.

The Solicitor: Are you in arrears with your calls?

Mr. Phillipson: You are very rude to ask that question.

The Chairman: The question is asked because if you are in arrears you have no right.

Mr. Tyler: He rose because you said you doubted whether I should get a seconder.

Mr. Shippey said his heart and soul was in electricity. He felt that they should do all they could for the interest of their little baby company. He spoke thus of the company because he believed in it; he thought that there was a lot of lighting to be done in the mines of Cornwall.

After a vote of thanks to the chairman, proposed by Mr. Shippey and seconded by Mr. Underell, the proceedings terminated.

THE LONDON AND PROVINCIAL ELECTRIC LIGHTING AND POWER GENERATING COMPANY (LIMITED).

THE first ordinary or statutory meeting of the above company was held on Thursday, the 7th inst., in Cannon Street Hotel, Lord Wallscourt presiding.

The secretary, G. H. Redwood, Esq., having read the notice convening the meeting,

The Chairman said: Gentlemen, I have a short *résumé* of the company which I am going to read to you. As you are no doubt aware, this, the first statutory meeting of the company is held in accordance with the Companies' Act within four months of registration. It is not usual at such meetings to trouble you with any statement of accounts. You will, no doubt, however, be desirous of receiving some particulars of the progress of your company since the allotment of shares, which took place on May 15th last, when the number of shares allotted, including vendor's shares, represented a total share capital of, say, £69,000. In the first place, to carry out the object of the company it was necessary to take suitable premises, in respect to which some delay occurred. Finally, however, it has been arranged to rent premises at 42, Newington Causeway, in the centre of a very important lighting district, which are now being fitted up as an exhibition of the company's system of lighting. These premises will be opened for the inspection of shareholders at an early date, of which due notice will be given. I need scarcely remind you, gentlemen, that in the practical adaptation, electrical lighting is yet still in its infancy (hear, hear), entailing the greatest care and caution in taking the first steps in respect to contracts. It should be here observed, that the directors have had under their consideration contracts for various important places—Malta, the Brighton Aquarium, &c., but up to the present time no contract sufficiently advantageous has been concluded. It will be satisfactory for you to learn that negotiations are pending, which if carried out in their present shape will, it is believed, give a wholly satisfactory result. It will be, however, obvious to you, seeing the competition in the field, that to disclose at this stage the names of places or persons would be highly impolitic. The field is large, and there is no lack of business.

In conclusion, the directors recommend the shareholders to use their best exertions in the interests of the company. If any gentleman has any question to ask, we shall be glad to hear him.

Mr. Sheridan would like to ask whether the manager of the company was satisfied with the progress made up to the present time with the negotiations.

The Manager said, that having assumed office only during the last three weeks, that was rather a short data to build upon in giving expression to any opinion as to the prospects of the company. It might suffice to say that proposals were daily forwarded to the office, and estimates and contracts furnished, but as to the actual business results, it was a little too early yet to go into such matters. He hoped that at their meeting next year, in May, that a good statement of accounts would be laid before the shareholders.

On the motion of Mr. Deere, seconded by Dr. Suckling, who said that they ought to be well satisfied at having a board with such business capabilities, a unanimous vote of thanks to the chairman and directors was adopted.

The Chairman briefly responded, and the proceedings terminated.

CABLE INTERRUPTED.—The Shanghai Nagasaki cable being interrupted, messages for China can only be forwarded by the Indo-European Company's line. All messages should be marked "*viâ* Indo."

QUOTATION has been granted to the South African Brush Electric Light and Power Company, Limited, shares.

SPECIAL Settling Day has been granted to the Provincial Brush Electric Light and Power Company, shares; and also to the South African Brush Electric Light and Power Company, Limited, shares.

TRAFFIC RECEIPTS.

The Cuba Submarine Telegraph Company, Limited. The number of messages passing over the lines of this company during the month of August was 2,581, estimated to produce £2,550, against 2,354 messages, producing £2,401, in the corresponding month of last year.

The Direct Spanish Telegraph Company, Limited. The estimated traffic receipts for the month of August, 1882, are £1,790, as against £1,507 in the corresponding period of last year.

The Great Northern Telegraph Company. The traffic receipts in August, 1882, were £23,360 from the 1st January to 31st August, 1882, £169,560, in the corresponding months of 1881, £158,240, and in the corresponding months of 1880, £154,075.

The Western and Brazilian Telegraph Company, Limited. The traffic receipts for the week ending 1st September, 1882, were £2,464, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company Limited.

West India and Panama Telegraph Company (Limited). The estimated receipts for the half-month ended the 31st August are £1,962, as compared with £1,763 in the corresponding period of 1881.

THE TELEGRAPHIC JOURNAL AND

Electrical Review.

VOL. XI.—No. 251.

THE ELECTRIC LIGHTING INDUSTRY.

THE universal interest in electric lighting which, until the summer months set in, had occupied the minds of financial men and the public generally, seems to have declined to a certain degree. Signs however are not wanting to show that there is a tendency for the new industry to regain its former hold upon the public mind. That such should be the case is most desirable, and the forthcoming winter should show a great advance in electric lighting operations. It is more than probable that a considerable number of the companies which have been floated during the present year would now have been on a much firmer footing had not the speculations in shares of certain leading companies made it a matter of doubt to intending investors and users of the light, as to the *bonâ fide* nature of the new ventures. It is scarcely to be expected that the shares of which we speak will ever again attain the fictitious value hitherto attached to them, for although such a contingency might happen under certain circumstances, we think it is in the power of other companies to restrict their value to a more reasonable amount. There can be no question but that the systems of several of the recent companies can be made to compete on favourable terms with those now so firmly established, if the undertaking is conducted on a right basis. We have never advocated the use of such a number of lamps in one circuit as to necessitate the production of a dangerously high electromotive force, and probably it is only a question of a short time for the limit in this matter to be settled by legislation. The majority of systems do not employ more than ten or twelve lamps on one circuit, and are therefore considered by the mass of interested, but uninformed, observers as being less efficient, economical, or simple, than those actuating twice or three times that number of lamps from one machine.

Leaving out the element of safety, which we must all admit forms a most important consideration in selecting a system of electric lighting, there are certain advantages attached to machines of low tension, even though the number of circuits must be increased two or threefold. It is not likely that a mishap would happen to more than one machine or one circuit at the same time, unless in such an extreme case as the steam or gas-engine breaking down. It is more to the manufacture of dynamo-electric machines that we wish now to draw attention. The present price of machines giving, say, two or three arc lights of the usual power is comparatively high compared with those constructed to produce sufficient current to operate twenty or more, and this may be partly accounted for by the rule of thumb method generally adopted in the designing of such machines.

Up to the present no systematic designing of machines for special work to be performed has been thoroughly entered into, the result being in many cases a wasteful expenditure of power. The field magnets of dynamo-electric machines, which form one of the chief items in their efficiency, are in most cases treated with the least consideration. The copper wire with which they are wound forms a great part of the expense of construction, and we have known frequent instances of machines manufactured so that a considerable portion of the wire round the field magnets has been absolutely useless, and therefore so much waste. After saturation point is reached by winding on a certain number of convolutions, any extra number of turns adds useless resistance to the circuit, and absorbs power inside which should be utilised externally. We shall be able, perhaps, to show our readers a practical example of this in a short time. The masses of metal composing the cores and projections of the electro-magnets are also important matters of consideration in designing the most effective and economical form of dynamo-electric machine. Mr. Edison has produced the only specially suitable machine for electric lighting by incandescence with which we are acquainted, and although this was criticised when exhibited in the Paris Exhibition by the correspondent of a leading newspaper as a machine such as no electrician would have designed, we imagine that he no longer holds the same view. Electric light companies preparing to compete with established systems should endeavour to construct the armatures and field-magnets of their machines according to the work to be done in the external circuit, and economy of manufacture, and therefore reduced selling prices will be the result. £5 worth of wire too much on a machine manufactured for a certain purpose will probably mean an addition of £10 or £12 to the price asked for its purchase.

The subject of electric lighting, however, has surely made sufficient headway to enable competing companies to lay down a course to pursue such as will command success. If not they have only themselves to blame; for, although the public interest is not now in such an excitable condition as at the beginning of the present year, it is probably of a more thoughtful and deeper nature, and those companies prepared to do good work will certainly not have to wait for patronage, for the innumerable advantages of the electric light are becoming daily more and more apparent.

A NEW PHOTO-ELECTRIC BATTERY.—A new battery, which gives a current on exposure to the action of light, has been devised by M. Saur. It consists of a square glass vessel, containing a solution of 15 parts common salt and 7 parts sulphate of copper in 106 of water. A porous vessel of mercury is placed in the solution. An electrode of platinum is in the mercury, and another of sulphuret of silver in the saline solution. The electrodes are connected by means [illegible] in a box shel- [illegible] it displaces the ne[illegible] that the sulphuret of si[illegible] the needle has come to rest, [illegible] the light of the sun the deviation [illegible] is suppressed the needle returns to it[illegible]; if a cloud passes before the sun while the b[illegible]posed to the light the variations of the needle indica[illegible] the fluctuations of the electric current. The effect of the battery is due to the action on the mercury of the bi-chloride of copper formed by the mixture of common salt and sulphate of copper. The proto-chloride of copper which is formed reduces the sulphuret of silver; but this reduction requires the intervention of the solar light, which determines the production of the photo-electric current.—*Les Mondes.*

We have said that the production of the ... the collecting frame is obtained when the ... beneath them a series of hollows, the fra...

sustained. A finger, *d* (fig. 20), placed upon its prolongation acts then upon a bar lodged in the vertical axle and produces, by the action of a series of levers and stops, the disengagement of a cam which puts in motion the printing mechanism. This mechanism is composed of two wheels, one called the printing-wheel and the other the type-wheel, mounted upon the same axis, with an arrangement which allows the relative displacement of the second in respect to the first, when it is necessary to make the impression of figures or of letters. This arrangement has been borrowed from the Hughes apparatus: we will not describe it. In the ordinary motion the printing-wheel and type-wheel have a common movement. In the printing-wheel each division is formed of a tooth and a hollow, in the type-wheel each division is subdivided into two parts containing two characters (a letter and a figure).

When the cam of fig. 20 is disengaged it enters a hollow of the printing wheel and accompanies this wheel in its movement until in a position symmetrical with respect to the line of the centres. It leaves then the hollow and takes up a second position by the action of a spring outside of the path of the teeth of the printing wheel. The fixed axle round which the cam turns bears on its prolongation an arm, called the printing arm, which is drawn along by the motion of the cam and projects the paper against the type wheel. A pin on the printing wheel acts at one part of its revolution upon the arm of a lever which turns around a horizontal axis and strikes again by means of its lower arm the cam, and restores it and the printing arm to their original position. This lever is represented at the upper part of fig. 21. The rest of the figure gives the details of the mechanism for the

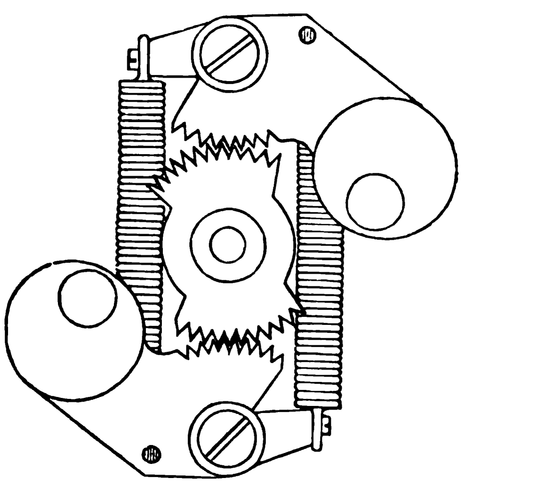

FIG. 22.

propulsion of the paper. The ribbon is furnished by a roller placed at the right of the receiver, and after several angles it eventually passes round the extremity of the printing arm, which is covered with cork, and finally is brought against a cylinder with a toothed surface and an adjacent roller pressed by a spring. The grooved cylinder is provided with two catches, *d* and d^1, the motion of which impels the paper. At the first stop and impression the catch, *d*, which is movable with the printing arm, draws on the cylinder; the catch, d^1, is fixed. The ribbon does not advance, but upon the right a certain length of paper, coming from the roller, is impelled by the rotary motion of the arm. On the return, the fixed catch retains the cylinder, the paper in contact of the roller does not move, but the portion which has received the impression slides over the cork and is replaced by another to receive the next character.

Fig. 19 represents a double receiver, doing service on two circuits, not consecutive, by the aid of a single motor and of a single combiner; the printing parts are double, and placed upon two opposite surfaces. The receiver is completed by two parts, called the speed regulator and brake regulator.

The speed regulator is arranged in such a manner as to be able at a given time to absorb a given portion of the power of the motor, the resisting couple varying in relation to the slight differences in the speed of rotation.

The fly-wheel of the apparatus turns eight times as quickly as the commutator, making from sixteen to twenty revolutions per second. The axle of the fly-wheel bears upon its prolongation two arms, terminated by sockets, into which are screwed two buttons, supporting two eccentric masses (fig. 22). Spiral springs, fixed at one end to the springs, and at the other end to the masses, tend to bring these back towards the centre, and act in the reverse direction to the centrifugal force developed by the rotation. The masses carry two small cork rubbers, sliding upon the concave surface of a metallic disc.

The speed regulator is completed by the brake regulator, which insures synchronous motion between the receivers and the distributor. Each double receiver possesses an electro-magnet, arranged near to the fly-wheel, the armature of which brings down a small hammer with a cork head. By the displacement of the armature, the hammer presses upon the circumference of the fly-wheel, and thus creates a resistance which diminishes the speed. Once in each revolution the sixth rubber of the distributor traverses the contact, called the brake-contact, and puts it in communication with the local battery which actuates the electro-magnet.

CAPANEMA'S PATENT PORCELAIN INSULATOR FOR BULLET-SHAPED WIRE-ATTACHMENT.

BEFORE describing this insulator we think it advisable to give a brief summary of the causes which lead to the decrease of electrical resistance observed in so many insulators after erection. It is not sufficient that a high insulating power is observed shortly after manufacture, but it is of the first importance that this insulation should remain as constant as possible, and Capanema's insulator has been designed to fulfil this condition.

Decrease of insulation or electrical resistance may be traced to the following causes :—

(1.) Chemical action which is set up when insulators of inferior quality are exposed to an atmosphere impregnated with acids or salts. (Porcelain insulators are less liable to be injured in this way than those of ebonite.)

(2.) Conducting films of dust and moisture, which frequently collect on the surface of insulators, and more readily upon a rough than a smooth surface.

(3.) Fissures and cracks caused by sudden and unequal expansion or contraction of the whole insulator or some of its parts. (The materials may, however, be so combined as to reduce this defect to a minimum. The quality and proportions of the substances employed in the manufacture of the porcelain should be chosen with a view of securing as constant an electrical resistance as practicable.)

(4.) Fissures caused by discharges of atmospheric electricity passing from the line-wire through the insulator to earth. (This occurs more readily when the insulator is of inferior quality, especially when the line-wire is attached to it by binding wire. In this case the latter, by encircling the upper part of the insulator, causes a large number of metallic points to be in contact with it, thus assisting the discharge through weak and defective places on the surface.)

(5.) The use of binding wire which frequently breaks and forms a direct contact. (When binding wire is wound round the insulator, its coating of zinc is invariably chafed off. It then rapidly oxidises through the moisture of the atmosphere, and rust is deposited over the surface of the insulator, thereby greatly reducing the insulation.)

Description of Capanema's Insulator.

This insulator has been designed with a view to avoid the above causes of defective insulation, and to obtain a method of securely fastening the line-wire to the insulator, while at the same time allowing repairs to be easily effected in case of breakage. The wire is securely attached to each insulator, so that in the event of a break occurring in any span, the insulators on each side hold the fractured wires and prevent them from slipping back in the adjoining spans.

Fig. 1 shows a section and fig. 2 a plan of this insulator. When a line is being constructed the wire is strained from pole to pole, and the place where it will rest in the insulator is marked. A bullet-shaped piece of tin-solder (the same as used for soldering joints) is then cast upon the wire at this mark and placed in the insulator. In the porcelain just above the bullet, there are two small holes for the reception of a pin which serves to keep the wire in its place. On properly-constructed lines, however, the wire is retained in the insulator by its own weight, and the pin is only required when the line has been erected in an irregular manner.

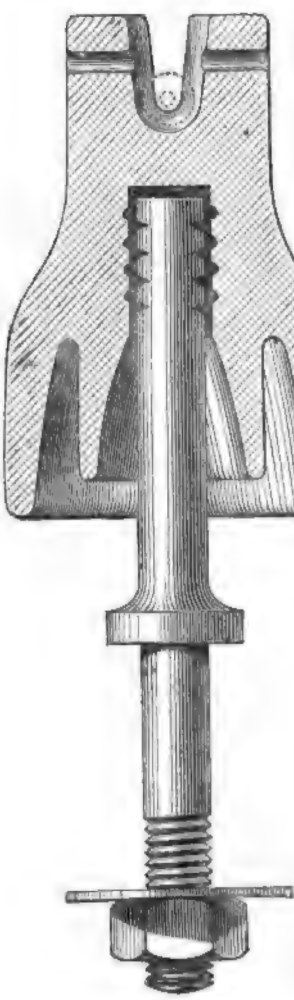

FIG. 1.

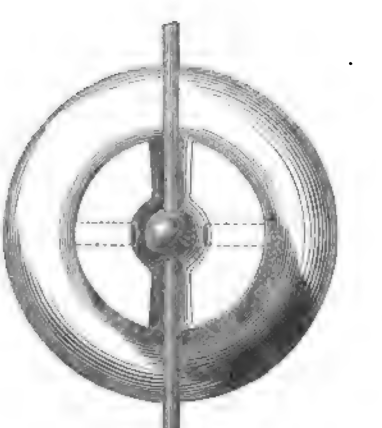

FIG. 2.

Experience has proved that the wire does not slip through the bullet, and that both are capable of bearing an equal strain. In order, however, to obtain complete security against slipping, the line-wire should be first dipped into the molten tin solder and heated, and the bullet then cast upon en the union of the metals becomes complete. facilitate this operation a bul et mould is used, through which the tin is allowed to flow, thus heating the wire, and after the latter has been sufficiently heated, the outflow of metal is stopped by a shutter, and the bullet is then formed. If the wire is not previously heated as above described, it slips through the bullet, just before its breaking strain is reached.

These insulators, which are of double-cup form, are made of the best highly-glazed porcelain, and the disadvantages attending the use of binding-wire (referred to in paragraphs 4 and 5), are avoided by the adoption of the bullet form of attachment. The line-wire, by means of this attachment, touches the insulator only at one point, so that discharges of atmospheric electricity are much less likely to destroy the insulator than when binding-wire is employed.

The method of fastening the line-wire by means of binding wire round each insulator is objectionable on account of its giving rise to loss of current during damp weather. In Capanema's insulator this leakage is greatly reduced by the small point of contact between the insulator and line-wire, and the electrical resistance remains consequently more constant.

Another advantage of the bullet attachment is, that it offers an easy and substantial way of suspending the line-wire, and in such a manner that the swinging motion of the latter is rendered harmless, and when faulty insulators require renewal, that operation can be carried out without touching the wire and interfering with the correspondence on the line.

These qualities render the insulator especially suitable for long lines with few wires in countries where constant supervision and repairs are difficult.

The favourable results obtained induced the Brazilian Government State Telegraph Department to adopt this insulator, and their lines, which are over 10,000 kilometres in length, have thereby been greatly improved in insulation.

In the discussion (on Mr. Sivewright's paper) which took place at a meeting of the Society of Telegraph Engineers on April 9th, 1879, Mr. Andrew Bell, Superintendent of the British Postal Telegraph Factories, referred to Capanema's insulator as possessing some "excellent features," and further remarked that "the metallic, or wire surface in contact with the insulator being very small diminished leakage, and another good point was that it would be free from a serious defect that attends the use of the common wire-binding. When the galvanising wears off the line and binding-wire, an oxide of iron soon covers the surface of the insulator and causes great leakage." These articles are manufactured by the firm of Messrs. Siemens Bros. & Co.

ELECTRIC CLOCKS AND TIME TELEGRAPHS.

By LOUIS H. SPELLIER.

(Abstract of a Paper read at the Stated Meeting of the Franklin Institute, May 17th, 1882.)

Two years ago I read a paper * before the Institute on the subject of "Electro-magnetic Time Telegraphs," or electric clocks that receive the time telegraphed in certain intervals from a weight or spring clock.

I then stated that "they mainly depend upon the action of one electro-magnet and one armature." The latter is a piece of iron which is attracted by the poles of the electro-magnet, when the telegraphing clock completes the circuit of a galvanic battery connected with it. As soon as the clock breaks the circuit again, the armature is repelled to its former position by a spring or weight. This movement of the armature turns a wheel which drives time-indicating machinery, and is repeated as often as this machinery requires to indicate the time of the clock, which makes or breaks the electric circuit.

Such instruments work very well if the action of the armature is needed about once every minute, but if repeated every second or two, then its imperfections become apparent. The movement of the armature is sudden and

* See ELECTRICAL REVIEW, June 1st, 1880.

rapid. With a lightning-like velocity the armature moves toward the magnet, and is checked instantaneously in its rapid progress just at a time when nearest to the magnet and most powerfully attracted. Naturally the wheel, which receives its impulse directly from the armature, moves with the same rapidity and is checked as suddenly. These sudden checks offered to the armature and wheel show their damaging results in a short time, and soon impair the correctness of such instruments.

With the aid of the accompanying cuts (figs. 1 and 2), which show the principle of my electro-magnetic escapement in its two main positions, I will be able to explain the manner in which I have corrected these evils by the invention of my system. Referring then to figs. 1 and 2, G is the electro-magnet, B is an iron wheel that has on its circumference the projections, H. Those projections are armatures. Fastened to the same axle with this iron wheel is the escape wheel, A, with the peculiarly shaped cog shown in the

FIG. 4.

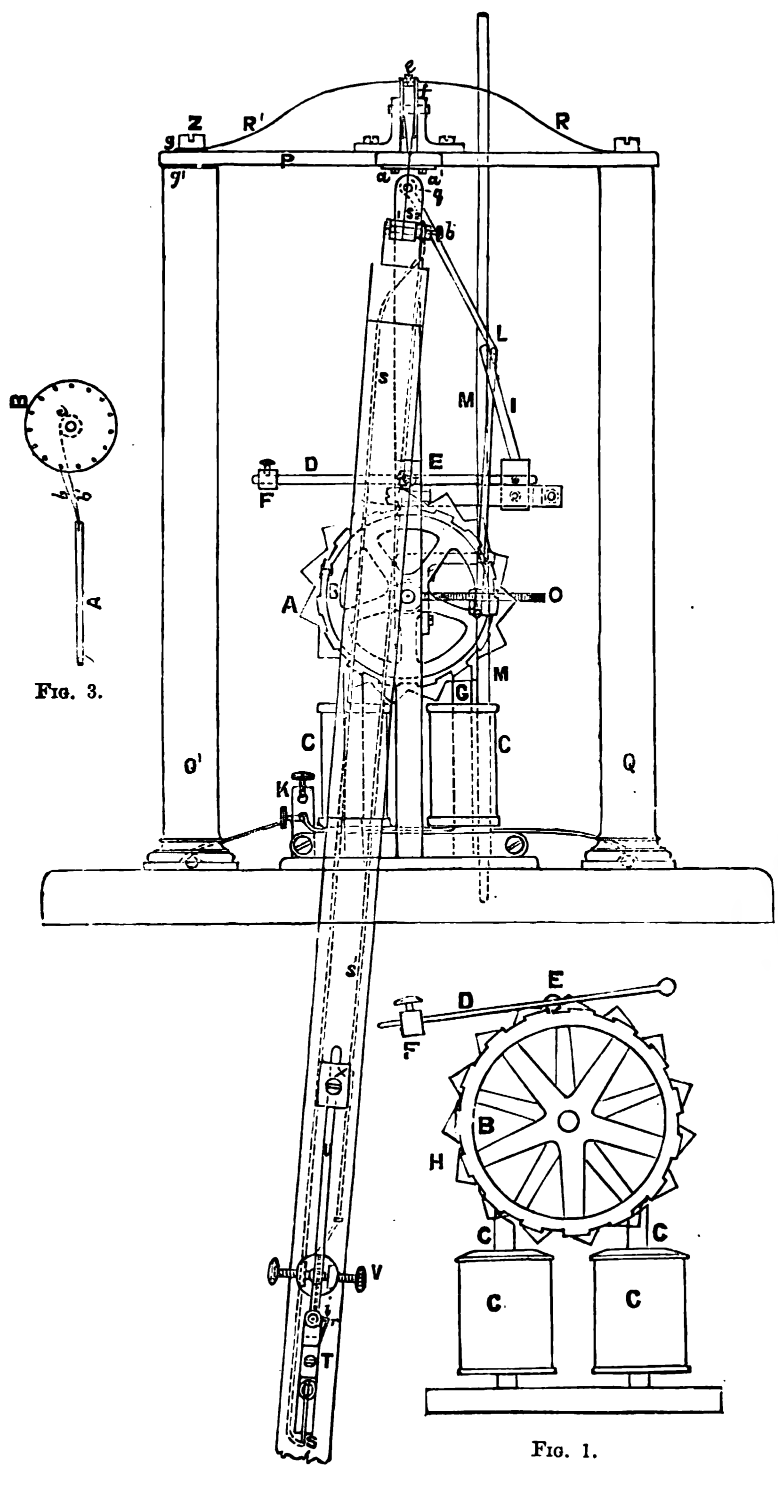

FIG. 3.

FIG. 1.

FIG. 5.

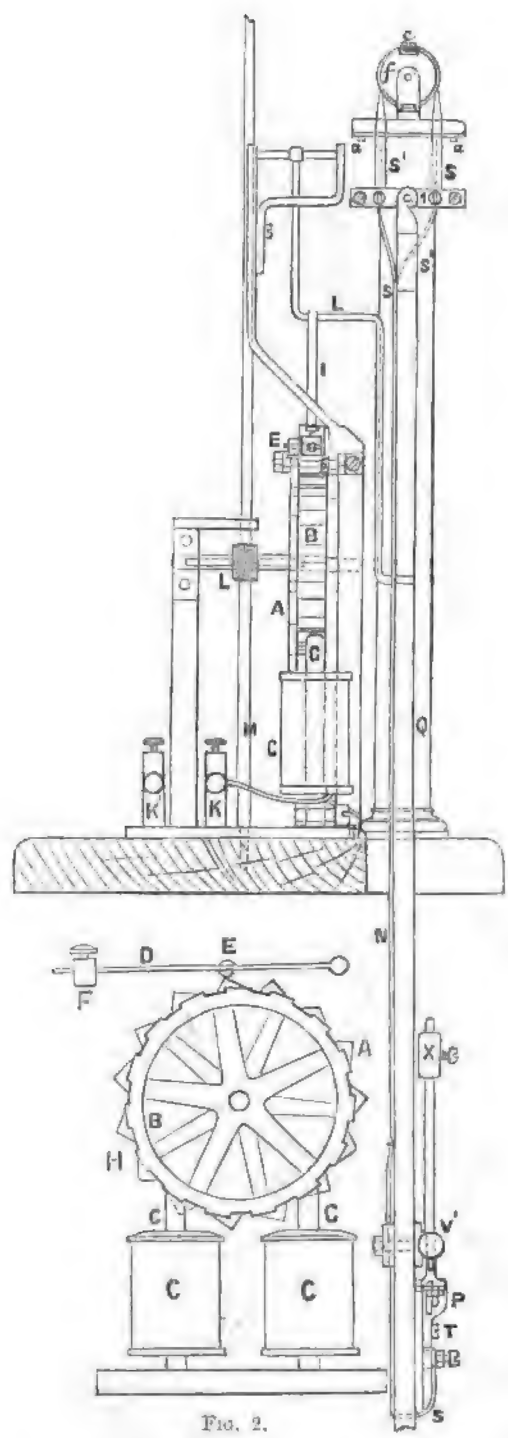

FIG. 2.

These clocks, as a rule, soon get out of repair, as may be seen by those in use at the Pennsylvania Railway Depot in this city. Their noise resembles that of a hammer striking forcibly upon an anvil, and it is only surprising that they run as long as they do.

To meet the above-mentioned faults of electric clocks is the purpose of the device of my electro-magnetic escapement, of which I exhibited here my first model about two years ago, and which is, indeed, the only second system of time telegraphs that is new in its fundamental principle that has been invented in almost half a century.

drawing. D is a lever with an adjustable weight at F, and presses by means of the pulley, E, on its circumference and rests at the bottom of the cog, when the electro-magnet is not charged with magnetism. When in that position, as shown by the drawing to the left, two of the armatures are very near to the poles of the electro-magnet.

At the moment when the electric current passes through the coil, C, and the poles, G, become magnetised, the two armatures will be attracted and take their position right over the poles of the electro-magnet as shown by the drawing to the right.

The escape-wheel, A, fastened to the same axle with B has moved with it and lifted up the lever, D, and has in its movement gone so far as to allow the pulley, E, to glide over the point of the cog and keep its position, shown on the drawing to the right, until the electric circuit is broken again; then the poles, G, become demagnetised, the armatures are no longer attracted, and the wheels, A and B, move under the pressure of the pulley until it has reached the bottom of the cog. By this movement the next succeeding two armatures have taken their position shown to the left, again ready to be attracted at the next closing of the electric current. In this manner is produced, by alternately opening and closing the circuit, a step-like movement of A and B. You will perceive that the object aimed at to avoid violent checks of the armature is completely achieved. Another advantage of no less significance is gained, namely, that it is impossible for the escape-wheel to move without an extra provision, at any given impulse, more than one cog.

Before I show the application of my escapement to time telegraphs I will explain the manner in which I make and break the circuit by means of a weight clock, in order to transmit the time to the electromagnetic escapement. This current-breaker, fig. 3, I have found to be very effective. B is a metal disc fastened to the axle of the escape-wheel of a clock. It has platinum pins vertically upon its face. C is another smaller platinum disc fastened to the pin-bearing disc, *b* and *b'* are two springs with platinum terminations. The spring, *b*, rests on the platinum disc, while *b'* forms the contact with the platinum pins.

When the disc moves with the escape-wheel of the clock it will complete the circuit of the galvanic battery, whenever the spring, *b'*, comes in contact with one of the pins, and when the spring is removed from the pin the circuit is broken.

I found this current breaker fully to answer its purpose and to meet all the requirements. It prevents by means of friction all accumulation of dust and oxidation and keeps the contact surface bright.

The best clocks for making the contact for time telegraphs are undoubtedly those provided with a gravity escapement invented by Edmund Becket. Clocks with gravity escapements allow an increase in the weight of the clock to such an extent as is needed for a secure metallic connection of this contact-breaker without affecting perceptibly the impulse given to the pendulum.

I now come to a subject of less general interest, but of not less importance, that of real electric clocks, where the moving power of the whole mechanism is electro-magnetism only. I called such clocks in my paper two years ago more of a scientific curiosity than a useful invention; and yet some of the most prominent philosophers and mechanicians have devoted their time and genius to their construction to make them correct time-pieces. The first who constructed such clocks was Bain, about forty-five years ago. At present the clocks of Dr. Hipp seem to take the lead, but although he claims great accuracy for them, they seem not to sustain the claim in every instance. One small specimen of his clocks is exhibited in the window of Mr. Thomas Shaw, Ridge Avenue, above Ninth Street, of our city. In principle I think it to be a step backwards, as it is but a modified and improved clock of the Bain type.

There are three main difficulties in the way of making electric pendulum clocks a success.

They are, first, the variation of the strength of the electric current of galvanic batteries; second, the danger that the current-breaker will not make a sufficiently secure contact for the passage of the electric current, since the contact is made by the pendulum, which has not in all cases sufficient surplus of power to make a secure contact; and, third, the obstruction which the current-breaker offers to the pendulum in its oscillations. Therefore, electric clocks can only be a success when the above-mentioned difficulties are avoided. I think I have met the difficulties successfully by a clock exhibited here to-night, presently to be explained.

I shall first explain the current-breaker of my clock, and to show how far it differs from those employed up to this day I will introduce this explanation by a brief description of the current-breaker now in use at the astronomical observatory in Paris.

There the pendulum of the clock has two side-extending metal arms. Each of these arms is provided with three screws with platinum terminations. Three levers, separately movable, but in metallic connection, corresponding to the screws, will be either in contact with, or removed from the screws as the pendulum moves to and fro. The levers and the arms are inserted into the circuit of a galvanic battery and an opening and closing of the same, corresponding to the oscillations of the pendulum, will be effected. That the pendulum meets with a comparatively great obstruction in its movement by such a current-breaker cannot well be disputed, and yet the contact cannot be formed with a great deal of force to make it as secure as desired, since the levers have to be very light so that they will not obstruct the pendulum too much in its movements.

I now will show how I effect with a new device of a current-breaker a secure and firm contact, and yet at the same time allow the pendulum to follow the course of its oscillations without meeting with any obstruction. Fig. 4 shows a front view of my electric clock, and fig. 5 a side view, in which N is the pendulum and T, V and V' its current-breaker. You see an upright standing lever, U, with a weight, X, on the top. Near its fulcrum are two screws, V V', against the one or the other the lever will rest, if the pendulum is out of its vertical position to one side or the other. Two electric wires, S S', coming down the pendulum rod are in metallic connection with the two suspension-springs, S S'; both springs are fastened together at *e* by an insulated substance, and each of these suspension-springs is again connected with its corresponding spring, R R'. Now let the poles of the galvanic battery be connected with the springs, R R', and set the pendulum oscillating. If the pendulum has its present position, the lever, U, rests against the screw, V, and forms a metallic contact with the screw. The screw is connected with one of the wires coming down the pendulum rod from one of the supension-springs, and the lever is again connected with the other wire coming from the other suspension-spring, so that the electric current can pass through the contact made by the lever, U, and the screw, V. If the pendulum has its position on the opposite side, the lever will bear against the screw, V'. This screw has an insulating substance upon its termination that keeps the circuit broken. Thus, by the movements of the pendulum to and fro the lever, U, will bear against one or the other screw, and make and break the electric circuit. The fall of the lever from one to the other screw is so small that it needs very careful watching to perceive it. The contact formed proves to be secure. It is made with a great deal of force, since it is formed very near the fulcrum of the lever. You will observe that this simple contrivance of my current-breaker removes two of the principal difficulties which electric clocks have to combat with. It now remains to show how I made the impulse given to the pendulum for its movements independent of the strength of the electric current acting upon the electro-magnet of the clock. The springs, R R', are connected with the electro-magnet and inserted into the circuit of the galvanic battery. You see in the drawing fastened to the axle of the lever, D, that moves the escape-wheel, an arm, I. Against this arm, rests the lever, L, with its fulcrum at *q*. The extension of this lever touches the pendulum, while resting on the arm, I, when the pendulum hangs in its vertical position.

Now, if the pendulum is moved to the left, as it is shown in fig. 4, the lever of the current-breaker will bear against the screw, V, and close the circuit. The armatures nearest to the magnet are attracted, and the lever, D, that moves the escape-wheel is raised, and with it the arm, I, is moved, which in turn raises the lever, L. There it remains until the pendulum has taken its position to the right. Then the lever of the current-breaker drops against the insulated screw, V', and the circuit is broken, then the lever, D, suddenly drops down, moving the escape-wheel, while the lever, L, drops against the pendulum and the pressure of its weight gives the pendulum the impulse for its oscillations. This action of the mechanism is repeated as the pendulum swings to and fro. If we now consider that the lever is always lifted up to the same height, and its weigh' ... is not subjected to any changes, the power, acting upo the ... the pendulum to keep up its oscillations, must be the s... me at every impulse given, without regard to the attracting ... force of the electro-magnet. It will be seen that this ele... ctric clock makes a firm contact for the electric current t... pass; and that it

does not obstruct the pendulum in the course of its movements, and also that it makes the movements of the pendulum independent of the strength of the galvanic current. This, I think, embraces all the elements necessary for a true timepiece.

Some few words are in place regarding some details of the clock, to make the entire mechanism understood.

Two hard rubber plates, *g* and *g'*, are essential to insulate the metal plate, P, from the screw, Z, and the post, Q, to prevent the current from going directly through the plate, P, from Q to Q', in which case the current would escape the passage through the current-breaker, and the circuit would be continuously closed.

To avoid the passage of the current through the holes in which the pivots of the lever, U, move, a spring, *p*, is fastened to the support of the lever, pressing against a platinum pin, *i*, at the axle of the lever. The pulley, *f*, over which the suspension-springs, S S' are laid, is of hard rubber, to keep the springs insulated. 1 and 2 are two bars, also of hard rubber, which support the pendulum, and between which the two ends of the suspension-springs are fastened. The plates *a* and *a'* are of the same material, and are used to hold the suspension-springs in their proper positions.

THE BRITISH ASSOCIATION.

[*Specially reported for the* ELECTRICAL REVIEW.]

A NEW FORM OF ARC LAMP.

[Paper read before Section G, Monday, August 28th. By Prof. G. FORBES.]

PROF. FORBES stated that this lamp was specially devised for powerful currents—for lighthouse lamps, or projectors, where a powerful current was used, and where there was some difficulty in feeding the carbons. It had been found necessary under such circumstances to have the power not only of causing the carbons to approach each other, but sometimes to cause them to rub slightly, and that was a point not usually required in the construction of an arc lamp. At the same time, the arc lamp he held differed from others in this, that the point where the light came from was fixed, and did not vary in the consumption of the carbon. The two supports for the carbons were both connected with racks, and there were pinions mounted in the same axes, but insulated from each other. The size of these pinions was so regulated that the one carbon moved twice as quickly as the other, and therefore always kept focus, which was a necessary point in lighthouse illumination. A shunt current passes through a ring, which is really the armature of a Gramme machine. The main current passes through an upper series of coils, while the derived current from the armature passes through a lower series. The carbons, of course, are at first in contact, but as they wear away the resistance of the arc increases, the current diminishes in the main circuit and increases in the derived one, which goes in an opposite direction to the other, and the effect is utilised on a worm wheel, which turns to feed the carbons, so that the position of the light is always kept constant. The main circuit is continually tending, by the mechanical arrangement of the lamp, to pull the carbons apart, and the derived circuit to keep them in contact. If the current is too weak, the main circuit separates them a little further, so that the regulation is always kept constant.

Mr. Preece remarked that there appeared to be a special inventive effort just now in the direction of new systems of arc lighting. There seemed to be a great deal of novelty and ingenuity about that which Prof. Forbes had exhibited, and he hoped that it would be a success in practice.

A NEW HAND DYNAMO MACHINE.

[Paper read before Section A, August 25th. By W. H. PREECE, F.R.S.]
